- **What kind of respiratory protection should HCWs use when transporting patients with suspected or confirmed infectious TB disease?** The risk assessment for the setting should consider the potential for shared air. Drivers, HCWs and other staff who are transporting patients with suspected or confirmed infectious TB disease in an enclosed vehicle should consider wearing an N95 disposable respirator. If the patient has symptoms or signs of infectious TB disease (e.g., productive cough or positive AFB sputum smear result), the patient should wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when other persons are present. Patients who cannot tolerate masks because of medical conditions should observe strict respiratory hygiene and cough etiquette procedures.
- **What type of respiratory protection should be used in the operating room (OR) by HCWs with facial hair or other factors that preclude proper fitting of an N95 respirator?** Will wearing a surgical or procedure mask underneath a PAPR solve this problem? HCWs with facial hair should not wear negative pressure respirators (e.g., N95 disposable respirators that require a tight faceseal). In the OR, HCWs with facial hair who are caring for a person with suspected or confirmed infectious TB disease should consult their infection-control committee and respirator manufacturers regarding optimal respiratory protection and adequate infection-control measures. The HCW in this case might wear a surgical or procedure mask to protect the surgical field underneath a loose-fitting PAPR. However, the user cannot be assured of proper operation unless the PAPR's manufacturer tested the PAPR over a surgical or procedure mask or N95 respirator. All respiratory-protection equipment should be used in accordance with the manufacturer's instructions.
- **Should bacterial filters be used routinely on the breathing circuits of all ventilators and anesthesia equipment on patients with suspected or confirmed infectious TB disease?** Yes, bacterial filters should be used routinely on the exhalation breathing circuits of patients with suspected or confirmed infectious TB disease to prevent exhaled air containing infectious droplet nuclei from contaminating the room air. Filters should be used on mechanical ventilators and also on hand-held ventilating bags (i.e., manual resuscitators [e.g., ambu-bags®]). The bacterial filter should be specified by the manufacturer to filter particles 0.3 µm in both the unloaded and the loaded states, with a filter efficiency of ≥95% (i.e., filter penetration of <5%) at the maximum design flow rates of the ventilator.
- **Who should not wear an N95 respirator?** Any HCW who is restricted from using a respirator because of medical reasons should not wear one nor should persons who cannot pass a fit test because of the presence of facial hair or other condition that interferes with the seal of the respirator to the face.
- **How long can I use my respirator for TB exposures before I discard it?** Disposable respirators can be functional for weeks to months and reused by the same HCW. Reuse is limited by hygiene, damage, and breathing resistance, and manufacturer instructions should be considered.
- **Should persons who perform maintenance on and replace filters on any ventilation system that is likely to be contaminated with *M. tuberculosis* wear a respirator?** Laboratory studies indicate that re-aerosolization of viable mycobacteria from HEPA filters and N95 disposable respirator filter media is unlikely under normal conditions; however, the risks associated with handling loaded HEPA filters in ventilation systems under field-use conditions have not been evaluated. Therefore, persons performing maintenance and replacing filters on any ventilation system that is likely to be contaminated with *M. tuberculosis* should wear a respirator (see Respiratory Protection) and adhere to local recommendations for eye protection and gloves.

Cough-Inducing and Aerosol-Generating Procedures

- **Should a bronchoscopic procedure be performed on a patient with TB disease?** If possible, bronchoscopic procedures should be avoided for patients with 1) a clinical syndrome consistent with infectious pulmonary or laryngeal TB disease and 2) in persons with positive AFB sputum smear results, because bronchoscopic procedures substantially increase the risk for transmission either through an airborne route or a contaminated bronchoscope. If the diagnosis of TB is suspected, consideration should be given to empiric antituberculosis treatment, but a bronchoscopic procedure might have the advantage of confirmation of the diagnosis with histologic specimens; collection of additional specimens, including post bronchoscopy sputum,

can increase the diagnostic yield and increase the opportunity to confirm an alternate diagnosis. Microscopic examination of three consecutive sputum specimens obtained at least 8 hours apart is recommended instead of bronchoscopy.

- **For ORs without an AII room, postoperative recovery is usually in the OR suite. Is this location acceptable?** If the OR has an anteroom, this location is acceptable. Reversible flow rooms (OR or isolation) are not recommended by CDC, AIA, or ASHRAE.

Acknowledgments

The authors acknowledge contributions from leaders of substantial medical, scientific, public health and labor organizations, and other experts in the fields of TB, HIV/AIDS, infection control, hospital epidemiology, microbiology, ventilation, industrial hygiene, nursing, dental practice, and emergency medical services.

Terms and Abbreviations Used in this Report

ACET	Advisory Council for the Elimination of Tuberculosis
ACGIH	American Conference of Governmental Industrial Hygienists
ACGIH	American Conference of Governmental Industrial Hygienists
ACGIH	American Conference of Governmental Industrial Hygienists
ACH	Air changes per hour
ACOG	American College of Obstetricians and Gynecologists
AERS	Adverse event reporting system
AFB	Acid-fast bacilli
AIA	American Institute of Architects
AIDS	Acquired immunodeficiency syndrome
AII	Airborne infection isolation
ALA	American Lung Association
ALT	Alanine aminotransferase
ANSI	American National Standards Institute
APF	Assigned protection factor
APIC	Association for Professionals in Infection Control and Epidemiology, Inc.
ART	Antiretroviral therapy
ASHRAE	American Society of Heating, Refrigerating, and Air-Conditioning Engineers, Inc.
AST	Aspartate aminotransferase
ATS	American Thoracic Society
BAMT	Blood assay for <i>Mycobacterium tuberculosis</i>
BCG	Bacille Calmette-Guérin
BIDR	Blinded independent duplicate reading
BMBL	Biosafety in Microbiological and Biomedical Laboratories
BSL	Biosafety level
BSC	Biological safety cabinet
CAV	Constant air volume
CDC	Centers for Disease Control and Prevention
CEL	Certified equipment list
CFM	Cubic feet per minute
CFR	Code of Federal Regulations
CoV	Coronavirus
CPL	Compliance policy directive

CT	Computed tomography
DHHS	U.S. Department of Health and Human Services
DNA	Deoxyribonucleic acid
DTBE	Division of Tuberculosis Elimination
DOT	Directly observed therapy
DTH	Delayed-type hypersensitivity
ED	Emergency department
EMS	Emergency medical service
EPA	Environmental Protection Agency
ESRD	End-stage renal disease
ETL	Electrical Testing Laboratories
FDA	U.S. Food and Drug Administration
FGI	Facility Guideline Institute
FPM	Feet per minute
HAART	Highly active antiretroviral therapy
HCW	Health-care worker
HEPA	High-efficiency particulate air
HIV	Human immunodeficiency virus
HMO	Health maintenance organization
HPLC	High-pressure liquid chromatograph
HVAC	Heating, ventilation, air conditioning
ICU	Intensive care unit
IDSA	Infectious Diseases Society of America
IFN- γ	Inteferon-gamma
IGRA	Interferon gamma release assay
INH	Isoniazid
IUATLD	International Union Against Tuberculosis and Lung Disease
JCAHO	Joint Commission on Accreditation of Healthcare Organizations
LTBI	Latent tuberculosis infection
MDR	TB Multidrug-resistant tuberculosis
MOTT	Mycobacterium other than tuberculosis
NAA	Nucleic acid amplification
NCID	National Center for Infectious Diseases
NIAID	National Institute of Allergy and Infectious Diseases
NIH	National Institutes of Health
NIOSH	National Institute for Occupational Safety and Health
NM	Nanometer
NNRTI	Nonnucleoside reverse transcriptase inhibitors
NPIN	National Prevention Information Network
NTCA	National Tuberculosis Controllers Association
NTM	Nontuberculous mycobacteria
OR	Operating room
OSHA	Occupational Safety and Health Administration
PAPR	Powered air-purifying respirator
PCP	Pneumocystis pneumonia

PCR	Polymerase chain reaction
PE	Protective environment
PET	Permissible exposure time
PI	Protease inhibitor
PPD	Purified protein derivative
PPE	Personal protective equipment
QC	Quality control
QFT	QuantiFERON®-TB test
QFT-G	QuantiFERON®-TB Gold test
QLFT	Qualitative fit test
QNFT	Quantitative fit test
REL	Recommended exposure limit
RFLP	Restriction fragment length polymorphism
RNA	Ribonucleic acid
RZ	Rifampin and pyrazinamide
SARS	Severe acute respiratory syndrome
SGOT	Serum glutamic-oxalacetic transaminase*
SGPT	Serum glutamic-pyruvic transaminase†
SWPF	Simulated workplace protection factor
TB	Tuberculosis
TNF-α	Tumor necrosis factor-alpha
TU	Tuberculin unit
TST	Tuberculin skin test
UL	Underwriters Laboratories
UV	Ultraviolet
UVGI	Ultraviolet germicidal irradiation
VAV	Variable air volume
WHO	World Health Organization
WPF	Workplace protection factor

* Older term for AST.

† Older term for ALT.

Glossary of Definitions

acid-fast bacilli (AFB) examination	A laboratory test that involves microscopic examination of a stained smear of a patient specimen (usually sputum) to determine if mycobacteria are present. A presumptive diagnosis of pulmonary tuberculosis (TB) can be made with a positive AFB sputum smear result; however, approximately 50% of patients with TB disease of the lungs have negative AFB sputum smear results. The diagnosis of TB disease is usually not confirmed until Mycobacterium tuberculosis is identified in culture or by a positive nucleic acid amplification (NAA) test result.
administrative controls	Managerial measures that reduce the risk for exposure to persons who might have TB disease. Examples include coordinating efforts with the local or state health department; conducting a TB risk assessment for the setting; developing and instituting a written TB infection-control plan to ensure prompt detection, airborne infection isolation (AII), and treatment of persons with suspected or confirmed TB disease; and

	screening and evaluating health-care workers (HCWs) who are at risk for TB disease or who might be exposed to <i>M. tuberculosis</i> .
aerosol	Dispersions of particles in a gaseous medium (e.g., air). Droplet nuclei are an example of particles that are expelled by a person with an infectious disease (e.g., by coughing, sneezing, or singing). For <i>M. tuberculosis</i> , the droplet nuclei are approximately 1–5 μm . Because of their small size, the droplet nuclei can remain suspended in the air for substantial periods and can transmit <i>M. tuberculosis</i> to other persons.
air change rate	Ratio of the airflow in volume units per hour to the volume of the space under consideration in identical volume units, usually expressed in air changes per hour (ACH).
air change rate (equivalent)	Ratio of the volumetric air loss rate associated with an environmental control (or combination of controls) (e.g., an air cleaner or ultraviolet germicidal irradiation [UVGI] system) divided by the volume of the room where the control has been applied. The equivalent air change rate is useful for describing the rate at which bioaerosols are removed by means other than ventilation.
air change rate (mechanical)	Ratio of the airflow to the space volume per unit time, usually expressed in air changes per hour (ACH).
air changes per hour (ACH)	Air change rate expressed as the number of air exchange units per hour.
airborne infection isolation (AII) precautions	The isolation of patients infected with organisms spread through airborne droplet nuclei 1–5 μm in diameter. This isolation area receives substantial ACH (≥ 12 ACH for new construction since 2001 and ≥ 6 ACH for construction before 2001) and is under negative pressure (i.e., the direction of the air flow is from the outside adjacent space [e.g., the corridor] into the room). The air in an AII room is preferably exhausted to the outside, but can be recirculated if the return air is filtered through an high efficiency particulate respirator (HEPA) filter.
AII room	A room designed to maintain AII. Formerly called negative pressure isolation room, an AII room is a single-occupancy patient-care room used to isolate persons with suspected or confirmed infectious TB disease. Environmental factors are controlled in AII rooms to minimize the transmission of infectious agents that are usually spread from person-to-person by droplet nuclei associated with coughing or aerosolization of contaminated fluids. AII rooms should provide negative pressure in the room (so that air flows under the door gap into the room), an air flow rate of 6–12 ACH, and direct exhaust of air from the room to the outside of the building or recirculation of air through a HEPA filter.
American Institute of Architects/Facility Guideline Institute (AIA/FGI)	A professional organization that develops standards for building design and construction, including ventilation parameters, and enforced by the Joint Commission on Accreditation of Healthcare Organizations.
American Society of Heating, Refrigerating, and Air-Conditioning Engineers, Inc. (ASHRAE)	A professional organization that develops guidelines for building ventilation.
aminotransaminases	Also called transaminases. Used to assess for hepatotoxicity in persons taking antituberculosis medications and include aspartate amino transferase (AST), serum glutamic oxalacetic transaminase, formerly SGOT, and amino alanine transferase, formerly ALT.

aminotransferases	Also called transaminases. Used to assess for hepatotoxicity in persons taking antituberculosis medications and include aspartate amino transferase (AST) (formerly serum glutamic oxalacetic transaminase) and amino alanine transferase (ALT) (formerly serum glutamic pyruvic transaminase).
anaphylactic shock	An often severe and sometimes fatal systemic reaction upon a second exposure to a specific antigen (as wasp venom or penicillin) after previous sensitization that is characterized especially by respiratory symptoms, fainting, itching, and hives.
anemometer	An instrument used to measure the velocity (speed) of air.
anergy	A condition in which a person has a diminished ability to exhibit delayed T-cell hypersensitivity to antigens because of a condition or situation resulting in altered immune function. An inability to react to a skin test is called cutaneous anergy. Skin tests for anergy (i.e., control antigens) have poor predictive value and are not recommended.
anteroom	Small room leading from a corridor into an AII room. An anteroom is separated from both the AII room and the corridor by doors. An anteroom can act as an airlock, preventing the escape of contaminants from the AII room into the corridor.
apical	Relating to or located at the tip (an apex).
assigned protection factor (APF)	The minimum anticipated protection provided by a properly worn and functioning respirator or class of respirators.
asymptomatic	Neither causing nor exhibiting signs or symptoms of disease.
Bacille Calmette-Guérin (BCG)	A vaccine for TB named after the French scientists Calmette and Guérin used in most countries where TB disease is endemic. The vaccine is effective in preventing disseminated and meningeal TB disease in infants and young children. It may have approximately 50% efficacy for preventing pulmonary TB disease in adults.
baseline TB screening	Screening HCWs for LTBI and TB disease at the beginning of employment. TB screening includes a symptom screen for all HCWs, and tuberculin skin tests (TSTs) or blood assay for <i>Mycobacterium tuberculosis</i> (BAMT) for those with previous negative test results for <i>M. tuberculosis</i> infection.
baseline TST or baseline BAMT	The TST or BAMT is administered at the beginning of employment to newly hired HCWs. If the TST method is used, for HCWs who have not had a documented negative test result for <i>M. tuberculosis</i> during the preceding 12 months, the baseline TST result should be obtained by using the two-step method. BAMT baseline testing does not need the two-step method.
biological safety cabinet (BSC)	A ventilated box that provides HCWs with a degree of protection against hazardous aerosols that are generated within it. BSC is the principal device used to contain infectious splashes or aerosols generated by multiple microbiology processes. BSC provides physical barriers and directional airflow to carry hazards away from the HCW. Maintenance is an essential part of ensuring proper BCS function.
Biosafety in Microbiological and Biomedical Laboratories (BMBL)	A publication of the U.S. Public Health Service that describes the combinations of standard and special microbiology practices, safety equipment, and facilities constituting biosafety levels (BSLs) 1–4, which are recommended for work with various infectious agents in laboratory settings. The recommendations are advisory and intended to provide a voluntary guide or code of practice.

biosafety levels (BSLs)	Four BSLs are described in Section III of BMBL that comprise combinations of laboratory practices and techniques, safety equipment, and laboratory settings.
blinded independent duplicate reading (BIDR)	Process in which two or more TST readers immediately measure the same TST result by standard procedures, without consulting or observing one another's readings, and record results. BIDRs help ensure that TST readers continue to read TST results correctly.
blood assay for Mycobacterium tuberculosis (BAMT)	A general term to refer to recently developed in vitro diagnostic tests that assess for the presence of infection with <i>M. tuberculosis</i> . This term includes, but is not limited to, IFN- γ release assays (IGRA). In the United States, the currently available test is QuantiFERON®-TB Gold test (QFT-G).
BAMT converter	A change from a negative to a positive BAMT result over a 2-year period.
boosting	When nonspecific or remote sensitivity to tuberculin purified protein derivative (PPD) in the skin test wanes or disappears over time, subsequent TSTs can restore the sensitivity. This process is called boosting or the booster phenomenon. An initially small TST reaction size is followed by a substantial reaction size on a later test, and this increase in millimeters of induration can be confused with a conversion or a recent <i>M. tuberculosis</i> infection. Two-step testing is used to distinguish new infections from boosted reactions in infection-control surveillance programs.
bronchoscopy	A procedure for examining the lower respiratory tract in which the end of the endoscopic instrument is inserted through the mouth or nose (or tracheostomy) and into the respiratory tree. Bronchoscopy can be used to obtain diagnostic specimens. Bronchoscopy also creates a high risk for <i>M. tuberculosis</i> transmission to HCWs if it is performed on an untreated patient who has TB disease (even if the patient has negative AFB smear results) because it is a cough-inducing procedure.
case	A particular instance of a disease (e.g., TB). A case is detected, documented, and reported.
cavity (pulmonary)	A hole in the lung parenchyma, usually not involving the pleural space. Although a lung cavity can develop from multiple causes, and its appearance is similar regardless of its cause, in pulmonary TB disease, cavitation results from the destruction of pulmonary tissue by direct bacterial invasion and an immune interaction triggered by <i>M. tuberculosis</i> . A TB cavity substantial enough to see with a normal chest radiograph predicts infectiousness.
clinical examination	A physical evaluation of the clinical status of a patient by a physician or equivalent practitioner.
close contact (TB)	A person who has shared the same air space in a household or other enclosed environment for a prolonged period (days or weeks, not minutes or a couple hours) with a person with suspected or confirmed TB disease. Close contacts have also been referred to as high-priority contacts because they have the highest risk for infection with <i>M. tuberculosis</i> .
cluster (TB)	A group of patients with LTBI or TB disease that are linked by epidemiologic, location, or genotyping data. Two or more TST conversions within a short period can be a cluster of TB disease and might suggest transmission within the setting. A genotyping cluster is

	two or more cases with isolates that have an identical genotyping pattern.
combination product surgical mask/N95 disposable respirator	Product certified by CDC's National Institute for Occupational Safety and Health (NIOSH) and cleared by the Food and Drug Administration (FDA) that provides both respiratory protection and bloodborne pathogen protection.
constant air volume (CAV)	A descriptor for an air-handling system which, as the name implies, supplies and exhausts air at a constant flow rate. The flow rate does not change over time based on temperature load or other parameters.
contact (TB)	Refers to someone who was exposed to <i>M. tuberculosis</i> infection by sharing air space with an infectious TB patient.
contact investigation	Procedures that occur when a case of infectious TB is identified, including finding persons (contacts) exposed to the case, testing and evaluation of contacts to identify LTBI or TB disease, and treatment of these persons, as indicated.
contagious	Describes a characteristic of a disease that can be transmitted from one living being to another through direct contact or indirect contact; communicable. The agent responsible for the contagious character of a disease is also described as being infectious; the usual culprits are microorganisms.
contraindication	Any condition, especially any condition of disease, which renders a certain line of treatment improper or undesirable.
conversion	See TST conversion.
conversion rate	The percentage of a population with a converted test result (TST or BAMT) for <i>M. tuberculosis</i> within a specified period. This is calculated by dividing the number of conversions among eligible HCWs in the setting in a specified period (numerator) by the number of HCWs who received tests in the setting over the same period (denominator) multiplied by 100.
culture	Growth of microorganisms in the laboratory performed for detection and identification in sputum or other body fluids and tissues. This test usually takes 2–4 weeks for mycobacteria to grow (2–4 days for most other bacteria).
cough etiquette	See respiratory hygiene and cough etiquette.
cross contamination	When organisms from one sample are introduced into another sample, causing a false-positive result.
delayed-type hypersensitivity (DTH)	Cell-mediated inflammatory reaction to an antigen, which is recognized by the immune system usually because of previous exposure to the same antigen or similar ones. Cell-mediated reactions are contrasted with an antibody (or humoral) response. DTH typically peaks at 48–72 hours after exposure to the antigen.
deoxyribonucleic acid	DNA fingerprinting is a clinical laboratory technique used to distinguish between different strains of <i>M. tuberculosis</i> and to help assess the likelihood of TB transmission.
differential pressure	A measurable difference in air pressure that creates a directional airflow between adjacent compartmentalized spaces.
directly observed therapy (DOT)	Adherence-enhancing strategy in which an HCW or other trained person watches a patient swallow each dose of medication. DOT is the standard care for all patients with TB disease and is a preferred option for patients treated for LTBI.

disposable respirator	A respirator designed to be used and then discarded; also known as a filtering-facepiece respirator. Respirators should be discarded after excessive resistance, physical damage, or hygiene considerations.
droplet nuclei	Microscopic particles produced when a person coughs, sneezes, shouts, or sings. These particles can remain suspended in the air for prolonged periods and can be carried on normal air currents in a room and beyond to adjacent spaces or areas receiving exhaust air.
drug-susceptibility test	A laboratory determination to assess whether an <i>M. tuberculosis</i> complex isolate is susceptible or resistant to antituberculosis drugs that are added to mycobacterial growth medium or are detected genetically. The results predict whether a specific drug is likely to be effective in treating TB disease caused by that isolate.
environmental control measures	Physical or mechanical measures (as opposed to administrative control measures) used to reduce the risk for transmission of <i>M. tuberculosis</i> . Examples include ventilation, filtration, ultraviolet lamps, AII rooms, and local exhaust ventilation devices.
epidemiologic cluster	A closely grouped series of cases in time or place.
erythema	Abnormal redness of the skin. Erythema can develop around a TST site but should not be read as part of the TST result.
expert TST trainer	A designated instructor who has documented TST training experience. This may include having received training on placing and reading multiple TST results.
exposed cohorts	Groups of persons (e.g., family members, co-workers, friends, club, team or choir members, persons in correctional facilities, or homeless shelter residents) who have shared the same air space with the suspected patient with TB disease during the infectious period. A person in the exposed cohort is a contact. See also contact and close contact.
exposure	The condition of being subjected to something (e.g., an infectious agent) that could have an adverse health effect. A person exposed to <i>M. tuberculosis</i> does not necessarily become infected. See also transmission.
exposure period	The coincident period when a contact shared the same air space as the index TB patient during the infectious period.
exposure site	A location that the index patient visited during the infectious period (e.g., school, bar, bus, or residence).
extrapulmonary TB	TB disease in any part of the body other than the lungs (e.g., kidney, spine, or lymph nodes). The presence of extrapulmonary disease does not exclude pulmonary TB disease.
false-negative TST or BAMT result	A TST or BAMT result that is interpreted as negative in a person who is actually infected with <i>M. tuberculosis</i> .
false-positive TST or BAMT result	A TST or BAMT result that is interpreted as positive in a person who is not actually infected with <i>M. tuberculosis</i> . A false-positive TST result is more likely to occur in persons who have been vaccinated with BCG or who are infected with nontuberculous mycobacteria (NTM).
facility	A physical building or set of buildings.
filtering-facepiece respirator	A type of air purifying respirator that uses a filter as an integral part of the facepiece or with the entire facepiece composed of the filtering medium.
fit check	See user-seal check.

fit factor	A quantitative estimate of the fit of a particular respirator to a specific person; typically estimates the ratio of the concentration of a substance in ambient air to its concentration inside the respirator when worn.
fit test	The use of a protocol to qualitatively or quantitatively evaluate the fit of a respirator on a person. See also QLFT and QNFT.
flutter strips	Physical indicators used to provide a continuous visual sign that a room is under negative pressure. These simple and inexpensive devices are placed directly in the door and can be useful in identifying a pressure differential problem.
genotype	The DNA pattern of <i>M. tuberculosis</i> used to discriminate among different strains.
health-care–associated	Broader term used instead of "nosocomial."
health-care setting	A place where health care is delivered.
health-care workers (HCWs)	All paid and unpaid persons working in health-care settings.
heating, ventilating, or air conditioning (HVAC)	Mechanical systems that provide either collectively or individually heating, ventilating, or air conditioning for comfort within or associated with a building.
high efficiency particulate air (HEPA) filter	A filter that is certified to remove $\geq 99.97\%$ of particles $0.3 \mu\text{m}$ in size, including <i>M. tuberculosis</i> –containing droplet nuclei; the filter can be either portable or stationary. Use of HEPA filters in building ventilation systems requires expertise in installation and maintenance.
high-pressure liquid chromatograph (HPLC)	Laboratory method used to identify Mycobacterium species by analysis of species-specific fatty acids called mycolic acids, which are present in the cell walls of mycobacteria.
human immunodeficiency virus (HIV) infection	Infection with the virus that causes acquired immunodeficiency syndrome (AIDS). A person with both LTBI and HIV infection is at high risk for developing TB disease.
hemoptysis	The expectoration or coughing up of blood or blood-tinged sputum; one of the symptoms of pulmonary TB disease. Hemoptysis can also be observed in other pulmonary conditions (e.g., lung cancer).
hypersensitivity	A state in which the body reacts with an exaggerated immune response to a foreign substance. Hypersensitivity reactions are classified as immediate or delayed, types I and IV, respectively. See also delayed-type hypersensitivity.
immunocompromised and immunosuppressed	Describes conditions in which at least part of the immune system is functioning at less than normal capacity. According to certain style experts, "immunocompromised" is the broader term, and "immunosuppressed" is restricted to conditions with iatrogenic causes, including treatments for another condition.
incentive	A gift given to patients to encourage or acknowledge their adherence to treatment.
incidence	The number of new events or cases of disease that develop during a specified period.
index case	The first person with TB disease who is identified in a particular setting. This person might be an indicator of a potential public health problem and is not necessarily the source case. See also source case or patient.

induration	The firmness in the skin test reaction; produced by immune-cell infiltration in response to the tuberculin antigen that was introduced into the skin. Induration is measured transversely by palpation, and the result is recorded in millimeters. The measurement is compared with guidelines to determine whether the test result is classified as positive or negative.
infection with <i>M. tuberculosis</i>	In some persons who are exposed to and who inhale <i>M. tuberculosis</i> bacteria, the bacteria are not promptly cleared by respiratory defense systems, and the bacteria multiply and are spread throughout the body, thereby infecting the exposed person. In the majority of persons who become infected, the body is able to fight the bacteria to stop the bacteria from growing, further establishing a latent state. The bacteria are inactive, but they remain alive in the body and can become active later. In other persons, the infection with <i>M. tuberculosis</i> can progress to TB disease more promptly. <i>M. tuberculosis</i> infection encompasses both latent TB infection and TB disease. See also latent TB infection and reinfection.
infectious	See contagious.
infectious droplet nuclei	Droplet nuclei produced by an infectious TB patient that can carry tubercle bacteria and be inhaled by others. Although usually produced from patients with pulmonary TB through coughing, aerosol-generating procedures can also generate infectious droplet nuclei.
infectious period	The period during which a person with TB disease might have transmitted <i>M. tuberculosis</i> organisms to others. For patients with positive AFB sputum smear results, the infectious period begins 3 months before the collection date of the first positive smear result or the symptom onset date (whichever is earlier) and ends when the patient is placed into AII or the date of collection for the first of consistently negative smear results. For patients with negative AFB sputum smear results, the infectious period extends from 1 month before the symptom onset date and ends when the patient is placed into AII (whichever was earlier).
interferon- γ release assays (IGRA)	A type of an ex vivo test that detects cell-mediated immune response to this cytokine. In the United States, QFT-G is a currently available IGRA.
isoniazid (INH)	A highly active antituberculosis chemotherapeutic agent that is a cornerstone of treatment for TB disease and the cornerstone of treatment for LTBI.
laryngeal TB	A form of TB disease that involves the larynx and can be highly infectious.
latent TB infection (LTBI)	Infection with <i>M. tuberculosis</i> without symptoms or signs of disease have manifested. See also Infection with <i>M. tuberculosis</i> .
manometer	An instrument used to measure pressure differentials (i.e., pressure inside an AII room relative to the corridor of the room).
Mantoux method	A skin test performed by intradermally injecting 0.1 mL of PPD tuberculin solution into the volar or dorsal surface of the forearm. This method is the recommended method for TST.
mask	A device worn over the nose and mouth of a person with suspected or confirmed infectious TB disease to prevent infectious particles from being released into room air.
mechanical ACH	Air change rate based on only the mechanical ventilation flowrates.

medical evaluation	An examination to diagnose TB disease or LTBI, to select treatment, and to assess response to therapy. A medical evaluation can include medical history and TB symptom screen, clinical or physical examination, screening and diagnostic tests (e.g., TSTs, chest radiographs, bacteriologic examination, and HIV testing), counseling, and treatment referrals.
meningeal TB	A serious form of TB disease involving the meninges, the covering of the brain. Meningeal TB can result in serious neurologic complications.
miliary TB	A serious form of TB disease sometimes referred to as disseminated TB. A dangerous and difficult form to diagnose of rapidly progressing TB disease that extends throughout the body. Uniformly fatal if untreated; in certain instances, it is diagnosed too late to save a life. Certain patients with this condition have normal findings or ordinary infiltrates on the chest radiograph.
mitogen	A substance that stimulates the growth of certain white blood cells. Mitogen is used as a positive control in BAMT tests.
multidrug-resistant tuberculosis (MDR TB)	TB disease caused by <i>M. tuberculosis</i> organisms that are resistant to at least INH and rifampin.
mycobacteria other than tuberculosis (MOTT)	See NTM.
Mycobacterium tuberculosis	The namesake member organism of <i>M. tuberculosis</i> complex and the most common causative infectious agent of TB disease in humans. In certain instances, the species name refers to the entire <i>M. tuberculosis</i> complex, which includes <i>M. bovis</i> , <i>M. african</i> , <i>M. microti</i> , <i>M. canettii</i> , <i>M. caprae</i> , and <i>M. pinnipedii</i> .
<i>M. tuberculosis</i> culture	A laboratory test in which the organism is grown from a submitted specimen (e.g., sputum) to determine the presence of <i>M. tuberculosis</i> . In the absence of cross-contamination, a positive culture confirms the diagnosis of TB disease.
N95 disposable respirator	An air-purifying, filtering-facepiece respirator that is $\geq 95\%$ efficient at removing 0.3 μm particles and is not resistant to oil. See also respirator.
negative pressure	The difference in air-pressure between two areas. A room that is under negative pressure has a lower pressure than adjacent areas, which keeps air from flowing out of the room and into adjacent rooms or areas. Also used to describe a nonpowered respirator. See also AII and AII room.
nontuberculous mycobacteria (NTM)	Refers to mycobacterium species other than those included as part of <i>M. tuberculosis</i> complex. Although valid from a laboratory perspective, the term can be misleading because certain types of NTM cause disease with pathologic and clinical manifestations similar to TB disease. Another term for NTM is mycobacterium other than tuberculosis (MOTT). NTM are environmental mycobacteria.
nosocomial	Acquired in a hospital. The broader term "health-care-associated" is used in this report.
nucleic acid amplification (NAA)	Laboratory method used to target and amplify a single DNA or RNA sequence usually for detecting and identifying a microorganism. The NAA tests for <i>M. tuberculosis</i> complex are sensitive and specific and can accelerate the confirmation of pulmonary TB disease.
periodic fit testing	Repetition of fit testing performed in accordance with local, state, and federal regulations. Additional fit testing should be used when 1) a new model of respirator is used, 2) a physical characteristic of the user

	changes, or 3) when the user or respiratory program administrator is uncertain that the HCW is obtaining an adequate fit.
pleural effusion	Abnormal accumulation of fluid between the lining of the lung and the chest wall. Persons with TB pleural effusions might also have concurrent unsuspected pulmonary or laryngeal TB disease. These patients should be considered contagious until infectious TB disease is excluded.
polymerase chain reaction (PCR)	A system for in vitro amplification of DNA that can be used for diagnosis of infections.
positive predictive value of a TST	The probability that a person with a positive TST result is actually infected with <i>M. tuberculosis</i> . The positive predictive value is dependent on the prevalence of infection with <i>M. tuberculosis</i> in the population being tested and on the sensitivity and specificity of the test.
potential ongoing transmission	A risk classification for TB screening, including testing for <i>M. tuberculosis</i> infection when evidence of ongoing transmission of <i>M. tuberculosis</i> is apparent in the setting. Testing might need to be performed every 8–10 weeks until lapses in infection controls have been corrected, and no further evidence of ongoing transmission is apparent. Use potential ongoing transmission as a temporary risk classification only. After corrective steps are taken, reclassify the setting as medium risk. Maintaining the classification of medium risk for at least 1 year is recommended.
powered air-purifying respirator (PAPR)	A respirator equipped with a tight-fitting facepiece (rubber facepiece) or loose-fitting facepiece (hood or helmet), breathing tube, air-purifying filter, cartridge or canister, and a fan. Air is drawn through the air-purifying element and pushed through the breathing tube and into the facepiece, hood, or helmet by the fan. Loose-fitting PAPRs (e.g., hoods or helmets) might be useful for persons with facial hair because they do not require a tight seal with the face.
prevalence	The proportion of persons in a population who have a disease at a specific time.
protection factor	A general term for three specific terms: 1) APF, 2) SWPF, and 3) WPF. These terms refer to different methods of defining adequacy of respirator fit. See also APF, SWPF, and WPF.
pulmonary TB	TB disease that occurs in the lung parenchyma, usually producing a cough that lasts ≥ 3 weeks.
purified protein derivative (PPD) tuberculin	A material used in diagnostic tests for detecting infection with <i>M. tuberculosis</i> . In the United States, PPD solution is approved for administration as an intradermal injection (5 TU per 0.1 mL), a diagnostic aid for LTBI (see TST). In addition, PPD tuberculin was one of the antigens in the first-generation QFT.
qualitative fit test (QLFT)	A pass-fail fit test to assess the adequacy of respirator fit that relies on the response of the person to the test agent.
quality control (QC)	A function to ensure that project tools and procedures are reviewed and verified according to project standards.
QFT and QFT-G	Types of BAMT that are in vitro cytokine assays that detects cell-mediated immune response (see also DTH) to <i>M. tuberculosis</i> in heparinized whole blood from venipuncture. This test requires only a single patient encounter, and the result can be ready within 1 day. In 2005, QuantiFERON(r)-TB was replaced by QuantiFERON(r)-TB Gold (QFT-G), which has greater specificity because of antigen selection.

	QFT-G appears to be capable of distinguishing between the sensitization caused by <i>M. tuberculosis</i> infection and that caused by BCG vaccination.
quantitative fit test (QNFT)	An assessment of the adequacy of respirator fit by numerically measuring the amount of leakage into the respirator.
recirculation	Ventilation in which all or the majority of the air exhausted from an area is returned to the same area or other areas of the setting.
recommended exposure limit (REL)	The occupational exposure limit established by CDC/NIOSH. RELs are intended to suggest levels of exposure to which the majority of HCWs can be exposed without experiencing adverse health effects.
reinfection	A second infection that follows from a previous infection by the same causative agent. Frequently used when referring to an episode of TB disease resulting from a subsequent infection with <i>M. tuberculosis</i> and a different genotype.
resistance	The ability of certain strains of mycobacteria, including <i>M. tuberculosis</i> , to grow and multiply in the presence of certain drugs that ordinarily kill or suppress them. Such strains are referred to as drug-resistant strains and cause drug-resistant TB disease. See also multidrug-resistant TB.
respirator	A CDC/NIOSH-approved device worn to prevent inhalation of airborne contaminants.
respiratory hygiene and cough etiquette	Procedures by which patients with suspected or confirmed infectious TB disease can minimize the spread of infectious droplet nuclei by decreasing the number of infectious particles that are released into the environment. Patients with a cough should be instructed to turn their heads away from persons and to cover their mouth and nose with their hands or preferably a cloth or tissue when coughing or sneezing.
respiratory protection	The third level in the hierarchy of TB infection-control measures after administrative and environmental controls is used because of the risk for exposure.
restriction fragment length polymorphism (RFLP)	A technique by which organisms can be differentiated by analysis of patterns derived from cleavage of their DNA. The similarity of the patterns generated can be used to differentiate strains from one another. See also genotype.
reversion	A subsequent TST or BAMT result that is substantially smaller than a previous test; reversion has been observed to be more likely when the intervening time between TSTs increases.
Rifampin	A highly active antituberculosis chemotherapeutic agent that is a cornerstone of treatment for TB disease.
screening (TB)	Measures used to identify persons who have TB disease or LTBI. See also symptom screen.
secondary (TB) case	A new case of TB disease that is attributed to recent transmission as part of the scenario under investigation. The period for "recent" is not defined but usually will be briefer than 2 years. Technically, all cases are secondary, in that they originate from other contagious cases.
simulated workplace protection factor (SWPF)	A surrogate measure of the workplace protection provided by a respirator.
smear (AFB smear)	A laboratory technique for preparing a specimen so that bacteria can be visualized microscopically. Material from the specimen is spread onto a glass slide and usually dried and stained. Specific smear, stain, and microscopy methods for mycobacteria are designed to optimally detect members of this genus. The slide can be scanned by light or fluorescent

high-power microscopy. These methods require ongoing quality assurance for prompt and reliable results. The results for sputum smears usually are reported as numbers of AFB per high-powered microscopy field or as a graded result, from +1 to +4. The quantity of stained organisms predicts infectiousness. See also AFB.

source case or patient	The person or the case that was the original source of infection for secondary cases or contacts. The source case can be, but is not necessarily, the index case.
source case investigation	An investigation to determine the source case could be conducted in at least two circumstances: 1) when a health-care setting detects an unexplained cluster of TST conversions among HCWs or 2) when TB infection or disease is diagnosed in a young child. The purposes of a source case investigation are to ascertain that the source case has been diagnosed and treated, to prevent further <i>M. tuberculosis</i> transmission, and to ensure that other contacts of that source case are also evaluated and, if indicated, provided treatment.
source control	A process for preventing or minimizing emission (e.g., aerosolized <i>M. tuberculosis</i>) at the place of origin. Examples of source-control methods are booths in which a patient coughs and produces sputum, BSCs in laboratories, and local exhaust ventilation.
spirometry	A procedure used to measure time expired and the volume inspired, and from these measurements, calculations can be made on the effectiveness of the lungs.
sputum	Mucus containing secretions coughed up from inside the lungs. Tests of sputum (e.g., smear and culture) can confirm pulmonary TB disease. Sputum is different from saliva or nasal secretions, which are unsatisfactory specimens for detecting TB disease. However, specimens suspected to be inadequate should still be processed because positive culture results can still be obtained and might be the only bacteriologic indication of disease.
sputum induction	A method used to obtain sputum from a patient who is unable to cough up a specimen spontaneously. The patient inhales a saline mist, which stimulates coughing from deep inside the lungs.
supervised TST administration	A procedure in which an expert TST trainer supervises a TST trainee who performs all procedures on the procedural observation checklist for administering TSTs.
supervised TST reading	A procedure in which an expert TST trainer supervises a TST trainee who performs all procedures on the procedural observation checklist for reading TST results.
suspected TB	A tentative diagnosis of TB that will be confirmed or excluded by subsequent testing. Cases should not remain in this category for longer than 3 months.
symptomatic	A term applied to a patient with health-related complaints (symptoms) that might indicate the presence of disease. In certain instances, the term is applied to a medical condition (e.g., symptomatic pulmonary TB).
symptom screen	A procedure used during a clinical evaluation in which patients are asked if they have experienced any departure from normal in function, appearance, or sensation related to TB disease (e.g., cough).
targeted testing	A strategy to focus testing for infection with <i>M. tuberculosis</i> in persons at high risk for LTBI and for those at high risk for progression to TB disease if infected.

tuberculosis (TB) disease	Condition caused by infection with a member of the <i>M. tuberculosis</i> complex that has progressed to causing clinical (manifesting symptoms or signs) or subclinical (early stage of disease in which signs or symptoms are not present, but other indications of disease activity are present [see below]) illness. The bacteria can attack any part of the body, but disease is most commonly found in the lungs (pulmonary TB). Pulmonary TB disease can be infectious, whereas extrapulmonary disease (occurring at a body site outside the lungs) is not infectious, except in rare circumstances. When the only clinical finding is specific chest radiographic abnormalities, the condition is termed "inactive TB" and can be differentiated from active TB disease, which is accompanied by symptoms or other indications of disease activity (e.g., the ability to culture reproducing TB organisms from respiratory secretions or specific chest radiographic finding).
TB case	A particular episode of clinical TB disease. Refers only to the disease, not to the person with the disease. According to local laws and regulation, TB cases and suspect TB cases must be reported to the local or state health department.
TB contact	A person who has shared the same air space with a person who has TB disease for a sufficient amount of time to allow possible transmission of <i>M. tuberculosis</i>.
TB exposure incident	A situation in which persons (e.g., HCWs, visitors, and inmates) have been exposed to a person with suspected or confirmed infectious TB disease (or to air containing <i>M. tuberculosis</i>), without the benefit of effective infection-control measures.
TB infection	See LTBI.
TB infection-control program	A program designed to control transmission of <i>M. tuberculosis</i> through early detection, isolation, and treatment of persons with infectious TB. A hierarchy of control measures are used, including 1) administrative controls to reduce the risk for exposure to persons with infectious TB disease and screening for HCWs for LTBI and TB disease, 2) environmental controls to prevent the spread and reduce the concentration of infectious droplet nuclei in the air, and 3) respiratory protection in areas where the risk for exposure to <i>M. tuberculosis</i> is high (e.g., AII rooms). A TB infection-control plan should include surveillance of HCWs who have unprotected high-risk exposure to TB patients or their environment of care.
TB screening	An administrative control measure in which evaluation for LTBI and TB disease are performed through initial and serial screening of HCWs, as indicated. Evaluation might comprise TST, BAMT, chest radiograph, and symptom screening. See also symptom screen.
TB screening program	A plan that health-care settings should implement to provide information that is critical in caring for HCWs and information and that facilitates detection of <i>M. tuberculosis</i> transmission. The TB screening program comprises four major components: 1) baseline testing for <i>M. tuberculosis</i> infection, 2) serial testing for <i>M. tuberculosis</i> infection, 3) serial screening for signs or symptoms of TB disease, and 4) TB training and education.
TB risk assessment	An initial and ongoing evaluation of the risk for transmission of <i>M. tuberculosis</i> in a particular health-care setting. To perform a risk assessment, the following factors should be considered: the community rate of TB, number of TB patients encountered in the setting, and the speed with which patients with TB disease are suspected, isolated, and

evaluated. The TB risk assessment determines the types of administrative and environmental controls and respiratory protection needed for a setting.

transmission	Any mode or mechanism by which an infectious agent is spread from a source through the environment or to a person (or other living organism). In the context of health-care–associated TB infection control, transmission is the airborne conveyance of aerosolized <i>M. tuberculosis</i> contained in droplet nuclei from a person with TB disease, usually from the respiratory tract, to another person, resulting in infection.
treatment for LTBI	Treatment that prevents the progression of infection into disease.
tuberculin skin test (TST)	A diagnostic aid for finding <i>M. tuberculosis</i> infection. A small dose of tuberculin is injected just beneath the surface of the skin (in the United States by the Mantoux method), and the area is examined for induration by palpation 48–72 hours after the injection. The indurated margins should be read transverse (perpendicular) to the long axis of the forearm. See also Mantoux method and PPD.
TST conversion	A change in the result of a test for <i>M. tuberculosis</i> infection wherein the condition is interpreted as having progressed from uninfected to infected. An increase of ≥ 10 mm in induration during a maximum of 2 years is defined as a TST conversion for the purposes of a contact investigation. A TST conversion is presumptive evidence of new <i>M. tuberculosis</i> infection and poses an increased risk for progression to TB disease. See also conversion rate.
tubercle bacilli	<i>M. tuberculosis</i> organisms.
tuberculin	A precipitate made from a sterile filtrate of <i>M. tuberculosis</i> culture medium.
tumor necrosis factor-alpha (TNF- α)	A small molecule (called a cytokine) discovered in the blood of animals (and humans) with tumors but which has subsequently been determined to be an essential host mediator of infection and inflammation. TNF- α is released when humans are exposed to bacterial products (e.g., lipopolysaccharide) or BCG. Drugs (agents) that block human TNF- α have been demonstrated to increase the risk for progression to TB disease in persons who are latently infected.
two-step TST	Procedure used for the baseline skin testing of persons who will receive serial TSTs (e.g., HCWs and residents or staff of correctional facilities or long-term-care facilities) to reduce the likelihood of mistaking a boosted reaction for a new infection. If an initial TST result is classified as negative, a second step of a two-step TST should be administered 1–3 weeks after the first TST result was read. If the second TST result is positive, it probably represents a boosted reaction, indicating infection most likely occurred in the past and not recently. If the second TST result is also negative, the person is classified as not infected. Two-step skin testing has no place in contact investigations or in other circumstances in which ongoing transmission of <i>M. tuberculosis</i> is suspected.
ulceration (TST)	A break in the skin or mucosa with loss of surface tissue.
ultraviolet germicidal radiation (UVGI)	Use of ultraviolet germicidal irradiation to kill or inactivate microorganisms.
UVGI lamp	An environmental control measure that includes a lamp that kills or inactivates microorganisms by emitting ultraviolet germicidal

irradiation, predominantly at a wavelength of 254 nm (intermediate light waves between visible light and radiographs). UVGI lamps can be used in ceiling or wall fixtures or within air ducts of ventilation systems as an adjunct to other environmental control measures.

user-seal check

Formerly called "fit check." A procedure performed after every respirator is donned to check for proper seal of the respirator.

variable air volume (VAV)

VAV ventilation systems are designed to vary the quantity of air delivered to a space while maintaining a constant supply air temperature to achieve the desired temperature in the occupied space. Minimum levels are mechanical, and outside air is maintained.

vesiculation

An abnormal elevation of the outer layer of skin enclosing a watery liquid; blister.

wheel

A small bump that is produced when a TST is administered. The wheal disappears in approximately 10 minutes after TST placement.

workplace protection factor (WPF) A measure of the protection provided in the workplace by a properly functioning respirator when correctly worn and used.

Guidelines for Preventing the Transmission of Mycobacterium tuberculosis in Health-Care Settings, 2005

TB Infection-Control Guidelines Work Group: Diane I. Bennett, MD, Michael F. Iademarco, MD, Paul A. Jensen, PhD, Lauren A. Lambert, MPH, Beverly Metchock, DrPH, Renee Ridzon, MD, Division of Tuberculosis Elimination, National Center for HIV, STD and TB Prevention, CDC (Currently with the Bill and Melinda Gates Foundation); Paul M. Arguin, MD, Denise M. Cardo, MD, Amy B. Curtis, PhD, Adelisa L. Panlilio, MD, Patricia M. Simone, MD, Division of Global Migration and Quarantine, National Center for Infectious Diseases, CDC; Jennifer L. Cleveland, DMD, Amy S. TABLE 1. Air changes per hour (ACH) and time required for removal efficiencies of 99% and 99.9% of airborne contaminants*

ACH	Minutes required for removal efficiency†	
	99%	99.9%
2	138	207
4	69	104
6	46	69
12	23	35
15	18	28
20	14	21
50	6	8
400	<1	1

* This table can be used to estimate the time necessary to clear the air of airborne *Mycobacterium tuberculosis* after the source patient leaves the area or when aerosol-producing procedures are complete.

† Time in minutes to reduce the airborne concentration by 99% or 99.9%.

BOX 1. Indications for two-step tuberculin skin tests (TSTs)

Situation	Recommended testing
No previous TST result	Two-step baseline TSTs
Previous negative TST result (documented or not) >12 months before new employment	Two-step baseline TSTs
Previous documented negative TST result ≤12 months before new employment	Single TST needed for baseline testing; this test will be the second-step
≥2 previous documented negative TSTs but most recent TST >12 months before new employment	Single TST; two-step testing is not necessary (result would have already boosted)
Previous documented positive TST result	No TST
Previous undocumented positive TST result*	Two-step baseline TST(s)
Previous BCG [†] vaccination	Two-step baseline TST(s)
Programs that use serial BAMT, [§] including QFT [¶] (or the previous version QFT ^{**})	See Supplement, Use of QFT-G ^{**} for Diagnosing <i>M. tuberculosis</i> Infections in Health-Care Workers (HCWs)

* For newly hired health-care workers and other persons who will be tested on a routine basis (e.g., residents or staff of correctional or long-term-care facilities), a previous TST is not a contraindication to a subsequent TST, unless the test was associated with severe ulceration or anaphylactic shock, which are substantially rare adverse events. If the previous positive TST result is not documented, administer two-step TSTs or offer BAMT. **SOURCES:** Aventis Pasteur. BOX 2. Interpretation of QuantiFERON(r)-TB Gold test (QFT-G) results

QFT-G result	Interpretation
Positive	
ESAT-6 or CFP-10* responsiveness detected	<i>Mycobacterium tuberculosis</i> infection probable
Negative	
No ESAT-6 and CFP-10 responsiveness detected	<i>M. tuberculosis</i> infection unlikely, but cannot be excluded, especially when
	1. any illness is consistent with TB disease, and
	2. the likelihood of progression to TB disease is increased (e.g., because of immunosuppression)
Indeterminate	Test not interpretable

* ESAT-6 is a 6-kDa early secretory antigenic target, and CFP-10 is 10-kDa culture filtrate protein.

FIGURE 1. The tuberculin skin test result in this picture should be recorded as 16 mm. The "0" mm ruler line is inside the edge of the left dot.

A48946859

BOX 3. Interpretations of tuberculin skin test (TST) and QuantiFERON(r)-TB test (QFT) results according to the purpose of testing for Mycobacterium tuberculosis infection in a health-care setting

Purpose of testing	TST	QFT
1. Baseline	1. ≥ 10 mm is considered a positive result (either first- or second-step); 0–9 mm is considered a negative result	1. Positive (only one-step)
2. Serial testing without known exposure	2. Increase of ≥ 10 mm is considered a positive result (TST conversion)	2. Change from negative to positive (QFT conversion)
3. Known exposure (close contact)	3. ≥ 5 mm is considered a positive result in persons who have a baseline TST result of 0 mm; an increase of ≥ 10 mm is considered a positive result in persons with a negative baseline TST result or previous follow-up screening TST result of >0 mm	3. Change to positive

TABLE 3. Standard drug regimens for treatment of latent TB infection (LTBI)*

Drugs	Months of duration	Interval	Minimum no. of standard doses*
Isoniazid (INH)	9 [†]	Daily	270
		Twice weekly	76
INH	6	Daily	180
		Twice weekly	52
Rifampin (RIF)	4	Daily	120
Rifampin/Pyrazinamide (RIF/PZA or RZ)	§	§	§

* **SOURCE:** American Thoracic Society, CDC. Targeted tuberculin testing and treatment of latent tuberculosis infection. MMWR 2000;49(No. RR-6).

[†]Nine months of INH is preferred, but 6 months of INH or 4 months of rifampin are acceptable alternatives.

§ Generally should not be offered for treatment of LTBI. **SOURCE:** CDC. Update: adverse event data and revised American Thoracic Society/CDC recommendations against the use of rifampin and pyrazinamide for treatment of latent tuberculosis infection—United States, 2003. MMWR 2003;52:735–9.

BOX 4. Conditions requiring caution in interpreting QuantiFERON(r)-TB Gold test results

- Human immunodeficiency virus infection or acquired immunodeficiency syndrome
- Immunosuppressive drugs, including those used for managing organ transplantation
- TNF*- α
- Diabetes mellitus
- Silicosis
- Chronic renal failure
- Certain hematological disorders (e.g., leukemias and lymphomas)
- Other specific malignancies (e.g., carcinoma of the head, neck, or lung)

* Tumor necrosis factor.

BOX 5. Factors affecting treatment decisions during the medical and diagnostic evaluation, by tuberculin skin test (TST) result

TST result ≥ 5 mm is positive	TST result ≥ 10 mm is positive	TST result ≥ 15 mm is positive*
- Persons infected with HIV[†] - Recent contacts of a person with tuberculosis (TB) disease - Persons with fibrotic changes on chest radiograph consistent with previous TB disease - Organ transplant recipients and other immunosuppressed persons (e.g., persons receiving ≥ 15 mg/day of prednisone for ≥ 1 month)[‡] - TB suspects[§]	- Recent immigrants (i.e., within the previous 5 years) from countries with a high incidence of TB disease - Persons who inject illicit drugs - Residents and employees (including health-care workers [HCWs])** of the following congregate settings - hospitals and other health-care facilities - long-term-care facilities (e.g., hospices and skilled nursing facilities) - residential facilities for patients with AIDS^{††} or other immunocompromising conditions - correctional facilities - homeless shelters - Mycobacteriology laboratory personnel - Persons with any of the following clinical conditions or immunocompromising conditions that place them at high risk for TB disease - diabetes mellitus - silicosis - chronic renal failure - certain hematologic disorders (e.g., leukemias and lymphomas) - other specific malignancies (e.g., carcinoma of the head, neck, or lung) - unexplained weight loss of $\geq 10\%$ of ideal body weight - gastrectomy - jejunoileal bypass - Persons living in areas with high incidence of TB disease - Children aged <4 years - Infants, children, and adolescents exposed to adults at high risk for developing TB disease - Locally identified groups at high risk	- Persons with no known risk factors for TB disease - HCWs who are otherwise at low risk for TB disease and who received baseline testing at the beginning of employment as part of a TB screening program**

* TST results ≥ 15 mm is positive in anyone. These persons should receive a symptom screen and do not need to be tested again. They should be evaluated for TB disease, and if disease is excluded, they should be offered treatment for latent TB infection (LTBI) if they have no contraindication to treatment.

[†] Human immunodeficiency virus.

[‡] The risk for TB disease in persons treated with corticosteroids increases with higher doses and longer duration of corticosteroid use.

[§] Persons with suspected TB disease can be treated based on the medical and diagnostic evaluation, regardless of the TST results.

** For HCWs who are otherwise at low risk for LTBI and progression to TB disease if infected and who received baseline testing at the beginning of employment as part of a TB infection-control screening program, a TST result of ≥ 15 mm (instead of ≥ 10 mm) is considered to be positive. Although a result of ≥ 10 mm on baseline or follow-up testing is considered a positive result for HCWs for the purposes of referral for medical and diagnostic evaluation, if the TST result is 10–14 mm on baseline or follow-up testing, the referring clinician might not recommend treatment of LTBI. SOURCE: Marsh BJ, SanVicente J, vonReyn E. Utility of dual skin tests to evaluate tuberculin skin test reactions of 10 to 14 mm in health-care workers. *Infect Control Hosp Epidemiol* 2003;24:821–4.

^{††} Acquired immunodeficiency syndrome.

FIGURE 2. An enclosing booth designed to sweep air past a patient with tuberculosis disease and collect the infectious droplet nuclei on a high efficiency particulate air (HEPA) filter

FIGURE 3. Room airflow patterns designed to provide mixing of air and prevent short-circuiting*

* Short-circuiting is the passage of air directly from the air supply to the exhaust.

FIGURE 4. Empirical relation between differential airflow, differential pressure, and leakage areas*

* Black solid lines indicate leakage areas. **SOURCE:** Hayden II CS, Fischbach TJ, Johnston OE, Hughes RT, Jensen PA. A model for calculating leakage areas into negative pressure isolation rooms. Cincinnati, OH: US Department of Health and Human Services, CDC; 1996.

FIGURE 5. Smoke tube testing and manometer placement to determine the direction of airflow into and out of a room

FIGURE 6. Cross-sectional view of a room indicating the location of negative pressure measurement*

* Airflow pressure at location 1 might differ from that at location 2. Measure pressure at location 2 for correct indication of negative pressure.

FIGURE 7. Fixed ducted room-air recirculation system using a high efficiency particulate air (HEPA) filter inside an air duct

FIGURE 8. Fixed ceiling-mounted room-air recirculation system using a high efficiency particulate air (HEPA) filter

BOX 6. Examples of ultraviolet germicidal irradiation (UVGI) signs

- Wall sign for upper-air UVGI

CAUTION
ULTRAVIOLET ENERGY
SWITCH OFF LAMPS BEFORE
ENTERING UPPER ROOM

- General warning posted near UVGI lamps

CAUTION
ULTRAVIOLET ENERGY
PROTECT EYES AND SKIN

- Warning posted on the door of air handlers where UVGI is present in ductwork

CAUTION
ULTRAVIOLET ENERGY IN DUCT
DO NOT SWITCH OFF SAFETY BUTTON
OR ACTIVATE LAMPS WITH DOOR OPEN

TABLE 4. Nonpowered air-purifying respirator filter classes certified in 42 CFR* 84

Resistance to efficiency filter degradation	Filter efficiencies [†]		
	95 (95%)	99 (99%)	100 (99.97%)
N (Not resistant to oil)	N95	N99	N100
R (Resistant to oil)	R95	R99	R100
P (Oil proof)	P95	P99	P100

* Code of Federal Regulations.

[†] The percentages in parenthesis indicate the minimum allowable laboratory filter efficiency value when challenged with 0.3 μ m particles.

Appendix A. Administrative, environmental, and respiratory-protection controls for selected health-care settings

Setting	Administrative controls [*]	Environmental controls [†]	Respiratory-protection controls [§]
Settings in Which Patients with Suspected or Confirmed Infectious Tuberculosis (TB) Disease are not Expected to be Encountered			
Triage only: Initial evaluation of patients who will transfer to another setting	- Implement a written infection-control plan for triage of patients with suspected or confirmed TB disease. Update annually. - Promptly recognize and transfer patients with suspected or confirmed TB disease to a facility that treats persons with TB disease. - Before transferring the patient out of this setting, hold the patient in an area separate from health-care workers (HCWs) and other persons.	- Settings in which patients with suspected or confirmed TB disease are rarely seen and not treated do not need an airborne infection isolation (AII) room. - Place any patient with suspected or confirmed TB disease in an AII room if available or in a separate room with the door closed, away from others and not in a waiting area. - Air-cleaning technologies (e.g., high efficiency particulate air [HEPA] filtration and ultraviolet germicidal irradiation [UVGI]) can be used to increase the number of equivalent air changes per hour (ACH) (see Supplement, Environmental Controls).	- Settings in which patients with suspected or confirmed TB disease are rarely seen and not treated do not need a respiratory-protection program. - If the patient has signs or symptoms of infectious TB disease (positive acid-fast bacilli [AFB] sputum smear result), consider having the patient wear a surgical or procedure mask (if possible) during transport, in waiting areas, or when others are present.
Inpatient Settings in Which Patients with Suspected or Confirmed Infectious TB Disease are Expected to be Encountered			
	- Perform an annual risk assessment for the setting. - Implement a written infection-control plan for the setting and evaluate and update annually. - Provide TB training, education, and screening for HCWs as part of the infection-control plan. - Establish protocols for problem evaluation. - When possible, postpone nonurgent procedures that might put HCWs at risk for possible exposure to <i>M. tuberculosis</i> until patients are determined to not have TB disease or are noninfectious. - Collaborate with state or local health departments when appropriate.	- In settings with a high volume of patients with suspected or confirmed TB disease, at least one room should meet requirements for an AII room (see Supplement, Environmental Controls). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls).	- For HCWs, visitors,[¶] and others entering the AII room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease consider having the patient wear a surgical or procedure mask, if possible, (e.g., if patient is not using a breathing circuit) during transport, in waiting areas, or when others are present.
Patient rooms	- Place patients with suspected or confirmed TB disease in an AII room. - Persons infected with human immunodeficiency virus (HIV) or who have other immunocompromising conditions should especially avoid exposure to persons with TB disease.	- At least one inpatient room should meet requirements for an AII room to be used for patients with suspected or confirmed infectious TB disease (see Supplement, Environmental Controls). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (Table 2).	- For HCWs, visitors,[¶] and others entering the AII room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, (e.g., if patient is not using a breathing circuit) during transport, in waiting areas, or when others are present.

Appendix A. (Continued) Administrative, environmental, and respiratory-protection controls for selected health-care settings

Setting	Administrative controls [*]	Environmental controls [†]	Respiratory-protection controls [‡]
Inpatient Settings in Which Patients with Suspected or Confirmed Infectious TB Disease are Expected to be Encountered			
Emergency departments (EDs)	- Implement a written infection-control plan for triage of patients with suspected or confirmed TB disease. Update annually. - Patients with signs or symptoms of infectious TB disease should be moved to an All room as soon as possible.	- In settings classified as medium risk or potential ongoing transmission, at least one room should meet requirements for an All room to be used for patients with suspected or confirmed infectious TB disease (see Supplement, Environmental Controls; Table 2). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls).	- For HCWs, visitors,[¶] and others entering the All room of a patient with suspected or confirmed TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible. (e.g., if patient is not using a breathing circuit) during transport, in waiting areas, or when others are present.
Intensive care units (ICUs)	Place patients with suspected or confirmed infectious TB disease in an All room, separate from HCWs and other patients, if possible.	- In settings with a high volume of patients with suspected or confirmed TB disease, at least one room should meet requirements for an All room to be used for such patients (see Supplement, Environmental Controls; Table 2). - Bacterial filters should be used routinely in breathing circuits of patients with suspected or confirmed TB disease and should filter particles 0.3 µm in size in unloaded and loaded situations with a filter efficiency of ≥95%.	- For HCWs, visitors,[¶] and others entering the All room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease and is suspected of being contagious (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible (e.g., if patient is not using a breathing circuit) during transport, in waiting areas, or when others are present.
Surgical suites	Schedule a patient with suspected or confirmed TB disease for surgery when a minimum number of HCWs and other patients are present, and as the last surgical case of the day to maximize the time available for removal of airborne contamination (see Supplement, Environmental Controls; Table 1). For postoperative recovery, place patients in a room that meets requirements for an All room.	- If a surgical suite has an operating room (OR) with an anteroom, that room should be used for TB cases. - If surgery is needed, use a room or suite of rooms that meet requirements for All rooms (see Supplement, Environmental Controls). - If an All or comparable room is not available for surgery or postoperative recovery, air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls). - If the health-care setting has an anteroom, reversible flow rooms (OR or isolation) are not recommended by the American Institute of Architects or American Society of Heating, Refrigerating and Air-conditioning Engineers, Inc. - Bacterial filters should be used routinely in breathing circuits of patients with suspected or confirmed TB disease and should filter particles 0.3 µm in size in an unloaded and loaded situation with a filter efficiency of ≥95%.	- For HCWs present during surgery of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators, unvalved, should be worn. - Standard surgical or procedure masks for HCWs might not have fitting or filtering capacity for adequate protection. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, before and after the procedure. - Valved or positive-pressure respirators should not be used because they do not protect the sterile surgical field.

Appendix A. (Continued) Administrative, environmental, and respiratory-protection controls for selected health-care settings

Setting	Administrative controls [*]	Environmental controls [†]	Respiratory-protection controls [‡]
Inpatient Settings in Which Patients with Suspected or Confirmed Infectious TB Disease are Expected to be Encountered			
Laboratories ^{**}	- Conduct a laboratory-specific risk assessment. - In general, biosafety level (BSL)-2 practices, procedures, containment equipment, and facilities are required for nonaerosol-producing manipulations of clinical specimens. BSL-3 practices, procedures, and containment equipment might be necessary for certain aerosol-generating or aerosol-producing manipulations.	- Environmental controls should meet requirements for clinical microbiology laboratories in accordance with guidelines by Biosafety in Microbiological and Biomedical Laboratories (BMBL) and the AIA. - Perform all manipulation of clinical specimens that could result in aerosolization in a certified class I or II biosafety cabinet (BSC).	For laboratory workers who manipulate clinical specimens (from patients with suspected or confirmed infectious TB disease) outside of a BSC, at least N95 disposable respirators should be worn.
Bronchoscopy suites ^{††}	- Use a dedicated room to perform bronchoscopy procedures. - If a patient with suspected or confirmed infectious TB disease must undergo bronchoscopy, schedule the procedure when a minimum number of HCWs and other patients are present, and schedule the patient at the end of the day. - Do not allow another procedure to be performed in the bronchoscopy suite until sufficient time has elapsed for adequate removal of <i>M. tuberculosis</i>-contaminated air (Table 1).	- Bronchoscopy suites should meet requirements for an AII room to be used for patients with suspected or confirmed infectious TB disease (Table 2). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls). - Closing ventilatory circuitry and minimizing opening of such circuitry of intubated and mechanically ventilated patients might minimize exposure. - Keep patients with suspected or confirmed infectious TB disease in the bronchoscopy suite until coughing subsides.	- For HCWs present during bronchoscopic procedures of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. Protection greater than an N95 (e.g., a full-facepiece elastomeric respirator or powered air-purifying respirator [PAPR]) should be considered. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, before and after the procedure.
Sputum induction and inhalation therapy rooms	- Implement a written infection-control plan in the setting. Update annually. - Use a dedicated room to perform sputum induction and inhalation therapy. - Schedule sputum induction and inhalation therapy when a minimum number of HCWs and other patients are present, and schedule the patient at the end of the day. - Do not perform another procedure in a booth or room where sputum induction or inhalation therapy on a patient with suspected or confirmed infectious TB disease was performed until sufficient time has elapsed for adequate removal of <i>M. tuberculosis</i>-contaminated air (Table 1).	- Perform sputum induction and inhalation therapy in booths with special ventilation, if possible. If booths are not available, sputum induction or inhalation therapy rooms should meet requirements for an AII room to be used for patients with suspected or confirmed infectious TB disease (Table 2). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls). - Keep patients with suspected or confirmed infectious TB disease in the sputum induction or inhalation therapy room after sputum collection or inhalation therapy until coughing subsides.	- For HCWs present during sputum induction and inhalation therapy of a patient with suspected or confirmed infectious TB disease, a respirator with a level of protection of at least N95 disposable respirators should be worn. Respiratory protection greater than an N95 (e.g., a full-facepiece elastomeric respirator or PAPR) should be considered (see Supplement, Respiratory Protection). - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, before and after the procedure.

Appendix A. (Continued) Administrative, environmental, and respiratory-protection controls for selected health-care settings

Setting	Administrative controls [*]	Environmental controls [†]	Respiratory-protection controls [‡]
Inpatient Settings in Which Patients with Suspected or Confirmed Infectious TB Disease are Expected to be Encountered			
Autopsy suites	• Ensure proper coordination between attending physician(s) and pathologist(s) for proper infection control and specimen collection during autopsies performed on bodies with suspected or confirmed infectious TB disease. • Allow sufficient time to elapse for adequate removal of <i>M. tuberculosis</i>-contaminated air (Table 1) before performing another procedure.	• Autopsy suites should meet ACH requirements for an All room to be used for bodies with suspected or confirmed TB disease (Table 2). • Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls). • Consider using local exhaust ventilation to reduce exposures to infectious aerosols and vapors from embalming fluids.	• For those present during autopsy on bodies with suspected or confirmed infectious TB disease, a respirator with a level of protection of at least an N95 should be worn. Protection greater than an N95 (e.g., a full-facepiece elastomeric respirator or PAPR) should be considered (see Supplement, Respiratory Protection), especially if aerosol generation is likely. • If another procedure cannot be delayed until sufficient time has elapsed for adequate removal of <i>M. tuberculosis</i>-contaminated air, staff should continue wearing respiratory protection while in the room (Table 1).
Embalming rooms	• Implement a written infection-control plan in the setting. Update annually.	• Embalming rooms should meet ACH requirements for an All room to be used for bodies with suspected or confirmed TB disease (Table 2). • Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls).	• For staff present during embalming procedures on bodies with suspected or confirmed infectious TB disease, a respirator with a level of protection of at least N95 should be worn. Protection greater than an N95 (e.g., a full-facepiece elastomeric respirator or PAPR) should be considered (see Supplement, Respiratory Protection), especially if aerosol generation is likely. • If another procedure cannot be delayed until sufficient time has elapsed for adequate removal of <i>M. tuberculosis</i>-contaminated air, staff should continue wearing respiratory protection while in the room.
Outpatient Settings^{§§} in Which Patients with Suspected or Confirmed Infectious TB Disease are Expected to be Encountered			
	• Perform an annual risk assessment for the setting. • Develop and implement a written infection-control plan for the setting and evaluate and update annually. • Provide TB training, education, and screening for HCWs as part of the infection-control plan. • Establish protocols for problem evaluation. • Collaborate with state or local health departments when appropriate.	• Environmental controls should be implemented based on the types of activities that are performed. • Patients with suspected or confirmed infectious TB disease requiring transport should be transported as discussed below under Emergency Medical Services (EMS).	• For HCWs, visitors,[¶] and others entering an All room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. • If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible (e.g., if patient is not using a breathing circuit), during transport, in waiting areas, or when others are present. • If risk assessment indicates that respiratory protection is needed, drivers or HCWs who are transporting patients with suspected or confirmed infectious TB disease in an enclosed vehicle should wear at least an N95 disposable respirator. The risk assessment should consider the potential for shared air.

Appendix A. (Continued) Administrative, environmental, and respiratory-protection controls for selected health-care settings

Setting	Administrative controls [*]	Environmental controls [†]	Respiratory-protection controls [‡]
Outpatient Settings in Which Patients with Suspected or Confirmed Infectious TB Disease are Expected to be Encountered			
TB treatment facilities ^{¶¶}	- Physically separate immunosuppressed patients from those with suspected or confirmed infectious TB. - Schedule appointments to avoid exposing HIV-infected or other severely immunocompromised persons to <i>M. tuberculosis</i>.	- If patients with TB disease are treated in the clinic, at least one room should meet requirements for an All room (Table 2). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls). - Perform all cough-inducing or aerosol-generating procedures by using environmental controls (e.g., booth) or in an All room. - Keep patients in the booth or All room until coughing subsides. - Do not allow another patient to enter the booth or All room until sufficient time has elapsed for adequate removal of <i>M. tuberculosis</i>-contaminated air (see Supplement, Environmental Controls; Table 1).	- For HCWs, visitors,[¶] and others entering the All room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when others are present.
Medical offices and ambulatory-care settings	Implement a written infection-control plan in the setting. Update annually.	In medical offices or ambulatory-care settings where patients with TB disease are treated, at least one room should meet requirements for an All room to be used for patients with suspected or confirmed infectious TB disease (Table 2).	- For HCWs in medical offices or ambulatory care settings with patients with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when others are present.
Dialysis units	Schedule dialysis for patients with TB disease when a minimum number of HCWs and other patients are present and at the end of the day to maximize the time available for removal of airborne contamination (Table 1).	- Perform dialysis for patients with suspected or confirmed infectious TB disease in a room that meets requirements for an All room (Table 2). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls).	- For HCWs, visitors,[¶] and others entering the All room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when others are present. - If risk assessment indicates the need for respiratory protection, drivers or HCWs who are transporting patients with suspected or confirmed infectious TB disease in an enclosed vehicle should wear at least an N95 disposable respirator. The risk assessment should consider the potential for shared air.

Appendix A. (Continued) Administrative, environmental, and respiratory-protection controls for selected health-care settings

Setting	Administrative controls [*]	Environmental controls [†]	Respiratory-protection controls [‡]
Outpatient Settings in Which Patients with Suspected or Confirmed Infectious TB Disease are Expected to be Encountered			
Dental-care settings	If possible, postpone dental procedures of patients with suspected or confirmed infectious TB disease until the patient is determined not to have TB disease or to be noninfectious.	- Treat patients with suspected or confirmed infectious TB disease in a room that meets requirements for an All room (Table 2). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls).	For dental staff performing procedures on a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn.
Nontraditional Facility-Based Settings			
	- Perform an annual risk assessment for the setting. - Develop and implement a written infection-control plan for the setting and evaluate and update annually. - Provide TB training, education, and screening for HCWs as part of the infection-control plan. - Establish protocols for problem evaluation. - Collaborate with state or local health departments when appropriate.	- Environmental controls should be implemented based on the types of activities that are performed (see Supplement, Environmental Controls). - Patients with suspected or confirmed infectious TB disease requiring transport should be transported as discussed in the EMS section.	- For HCWs, visitors,[§] and others entering the All room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible (e.g., if patient is not using a breathing circuit), during transport, in waiting areas, or when others are present.
EMS	Include exposed emergency medical HCWs in the contact investigation of patients with TB disease if administrative, environmental, and respiratory-protection controls for TB infection control were not followed.	- Patients with suspected or confirmed infectious TB disease requiring transport should be transported in an ambulance whenever possible. The ambulance ventilation system should be operated in the non-recirculating mode, and the maximum amount of outdoor air should be provided to facilitate dilution. If the vehicle has a rear exhaust fan, use this fan during transport. Airflow should be from the cab (front of vehicle), over the patient, and out the rear exhaust fan. - If an ambulance is not used, the ventilation system for the vehicle should bring in as much outdoor air as possible, and the system should be set to non-recirculating. If possible, physically isolate the cab from the rest of the vehicle and have the patient sit in the back.	- If risk assessment indicates the need for respiratory protection, drivers or HCWs who are transporting patients with suspected or confirmed infectious TB disease in an enclosed vehicle should wear at least an N95 disposable respirator. The risk assessment should consider the potential for shared air. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when others are present.

Appendix A. (Continued) Administrative, environmental, and respiratory-protection controls for selected health-care settings

Setting	Administrative controls*	Environmental controls†	Respiratory-protection controls‡
Nontraditional Facility-Based Settings			
Medical settings in correctional facilities	- Follow recommendations for inpatient and outpatient settings as appropriate. In waiting rooms or areas, follow recommendations for TB treatment facilities. - If possible, postpone transporting patients with suspected or confirmed infectious TB disease until they are determined not to have TB disease or to be noninfectious.	- At least one room should meet requirements for an AII room (Table 2). - Air-cleaning technologies (e.g., HEPA filtration and UVGI) can be used to increase the number of equivalent ACH (see Supplement, Environmental Controls). - When transporting patients with suspected or confirmed infectious TB disease in a vehicle (ideally an ambulance), if possible, physically isolate the cab (the front seat) from rest of the vehicle, have the patient sit in the back seat, and open the windows.	- For HCWs or others entering the AII room of a patient with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when others are present.
Home-based health-care and outreach settings	- Patients and household members should be educated regarding the importance of taking medications, respiratory hygiene and cough etiquette procedures, and proper medical evaluation. - If possible, postpone transporting patients with suspected or confirmed infectious TB disease until they are determined not to have TB disease or to be noninfectious. - Certain patients can be instructed to remain at home until they are determined not to have TB disease or to be noninfectious.	Do not perform cough-inducing or aerosol-generating procedures unless appropriate environmental controls are in place (see Supplement, Environmental Controls), or perform those procedures outside, if possible.	- For HCWs entering the homes of patients with suspected or confirmed infectious TB disease, at least N95 disposable respirators should be worn. - For HCWs transporting patients with suspected or confirmed infectious TB disease in a vehicle, consider at least an N95 disposable respirator. - If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when others are present.
Long-term-care settings (e.g., hospices and skilled nursing facilities)	Patients with suspected or confirmed infectious TB disease should not be treated in a long-term-care setting, unless proper administrative and environmental controls and a respiratory-protection program are in place.	Do not perform cough-inducing or aerosol-generating procedures unless appropriate infection controls are in place (see Supplement, Environmental Controls), or perform those procedures outside, if possible.	If the patient has signs or symptoms of infectious TB disease (positive AFB sputum smear result), consider having the patient wear a surgical or procedure mask, if possible, during transport, in waiting areas, or when others are present.

* Administrative controls must be implemented to ensure the effectiveness of environmental controls and respiratory-protection programs, and should be in place for all settings where patients with suspected or confirmed TB disease are expected to be encountered. Administrative controls include a written TB infection-control plan (which should be reassessed at least annually), assignment of responsibility for the plan, setting risk assessment, HCW risk classification, HCW training and education, and a TB screening program to test HCWs for infection with *M. tuberculosis*.

† Environmental controls include local exhaust and general ventilation (i.e., achieving negative pressure), using AII rooms, and air-cleaning methods (i.e., HEPA filtration and UVGI).

‡ All settings where patients with suspected or confirmed TB disease will be encountered need to have a respiratory-protection program. A respiratory-protection program might not be necessary for settings where patients with TB disease are not encountered or where a procedure exists for the prompt transfer of patients with suspected or confirmed TB disease to a setting where they can be evaluated.

§ Visitors with suspected or confirmed TB disease should not have contact with patients, including contact with those who have suspected or confirmed TB disease.

** Laboratories that are not based in inpatient settings should observe the same TB infection-control measures as laboratories in inpatient settings.

†† Certain bronchoscopy suites are built to have positive pressure.

§§ Although the majority of these settings are routinely considered "outpatient," they might be part of inpatient services in certain settings. If so, follow the recommendations for inpatient settings for patient rooms.

¶¶ TB treatment facilities can include TB clinics, infectious disease clinics, or pulmonary clinics.

Appendix B. Tuberculosis (TB) risk assessment worksheet

This model worksheet should be considered for use in performing TB risk assessments for health-care settings and nontraditional facility-based settings. Facilities with more than one type of setting will need to apply this table to each setting.

Scoring: ✓ or Y = Yes X or N = No NA = Not Applicable

1. Incidence of TB

- a. What is the incidence of TB in your community (county or region served by the health-care setting), and how does it compare with the state and national average?
- b. What is the incidence of TB in your facility and specific settings, and how do those rates compare? (Incidence is the number of TB cases in your community during the previous year. A rate of TB cases per 100,000 persons should be obtained for comparison.)^{*} This information can be obtained from the state or local health department.

Rate

Community _____
 State _____
 National _____
 Facility _____
 Department 1 _____
 Department 2 _____
 Department 3 _____

- c. Are patients with suspected or confirmed TB disease encountered in your setting (inpatient and outpatient)?

- 1) If yes, how many are treated in your health-care setting in 1 year? (Review laboratory data, infection-control records, and databases containing discharge diagnoses for this information.)

No. patients

Year	No. patients	
	Suspected	Confirmed
1 year ago	_____	_____
2 years ago	_____	_____
5 years ago	_____	_____

- 2) If no, does your health-care setting have a plan for the triage of patients with suspected or confirmed TB disease?

- d. Currently, does your health-care setting have a cluster of persons with confirmed TB disease that might be a result of ongoing transmission of *Mycobacterium tuberculosis*?

2. Risk Classification

a. Inpatient settings

- 1) How many inpatient beds are in your inpatient setting?
- 2) How many patients with TB disease are encountered in the inpatient setting in 1 year? (Review laboratory data, infection-control records, and databases containing discharge diagnoses.)
- 3) Depending on the number of beds and TB patients encountered in 1 year, what is the risk classification for your inpatient setting?

Quantity _____

Previous year _____

5 years ago _____

___ Low risk
 ___ Medium risk
 ___ Potential ongoing transmission

- 4) Does your health-care setting have a plan for triaging patients with suspected or confirmed TB disease?

b. Outpatient settings

- 1) How many TB patients are evaluated at your outpatient setting in 1 year? (Review laboratory data, infection-control records, and databases containing discharge diagnoses for this information.)

Previous year _____

5 years ago _____

- 2) Is your health-care setting a TB clinic? (If yes, a classification of at least medium risk is recommended.)

- 3) Does evidence exist that a high incidence of TB disease has been observed in the community that the health-care setting serves?

- 4) Does evidence exist of person-to-person transmission of *M. tuberculosis* in the health-care setting? (Use information from case reports. Determine if any TST or blood assay for *M. tuberculosis* [BAMT] conversions have occurred among health-care workers [HCWs].)

- 5) Does evidence exist that ongoing or unresolved health-care-associated transmission has occurred in the health-care setting (based on case reports)?

- 6) Does a high incidence of immunocompromised patients or HCWs in the health-care setting exist?

- 7) Have patients with drug-resistant TB disease been encountered in your health-care setting within the previous 5 years?

Year encountered _____

- 8) When was the first time a risk classification was done for your health-care setting?

Date of classification _____

- 9) Considering the items above, would your health-care setting need a higher risk classification?

Appendix B. (Continued) Tuberculosis (TB) risk assessment worksheet

_____ 10) Depending on the number of TB patients evaluated in 1 year, what is the risk classification for your outpatient setting (Appendix C)?

_____ 11) Does your health-care setting have a plan for the triage of patients with suspected or confirmed TB disease?

c. Nontraditional facility-based settings

_____ 1) How many TB patients are encountered at your setting in 1 year?

_____ 2) Does evidence exist that a high incidence of TB disease has been observed in the community that the setting serves?

_____ 3) Does evidence exist of person-to-person transmission of *M. tuberculosis* in the setting?

_____ 4) Have any recent TST or BAMT conversions occurred among staff or clients?

_____ 5) Is there a high incidence of immunocompromised patients or HCWs in the setting?

_____ 6) Have patients with drug-resistant TB disease been encountered in your health-care setting within the previous 5 years?

_____ 7) When was the first time a risk classification was done for your setting?

_____ 8) Considering the items above, would your setting require a higher risk classification?

_____ 9) Does your setting have a plan for the triage of patients with suspected or confirmed TB disease?

_____ 10) Depending on the number of patients with TB disease who are encountered in a nontraditional setting in 1 year, what is the risk classification for your setting (Appendix C)?

3. Screening of HCWs for *M. tuberculosis* infection

_____ a. Does the health-care setting have a TB screening program for HCWs?

If yes, which HCWs are included in the TB screening program? (check all that apply)

_____ Physicians	_____ Service workers
_____ Mid-level practitioners (nurse practitioners [NP] and physician's assistants [PA])	_____ Janitorial staff
_____ Nurses	_____ Maintenance or engineering staff
_____ Administrators	_____ Transportation staff
_____ Laboratory workers	_____ Dietary staff
_____ Respiratory therapists	_____ Receptionists
_____ Physical therapists	_____ Trainees and students
_____ Contract staff	_____ Volunteers
_____ Construction or renovation workers	_____ Others _____

_____ b. Is baseline skin testing performed with two-step TST for HCWs?

_____ c. Is baseline testing performed with QuantiFERON®-TB or other BAMT for HCWs?

_____ d. How frequently are HCWs tested for *M. tuberculosis* infection?

_____ e. Are *M. tuberculosis* infection test records maintained for HCWs?

_____ f. Where are test records for HCWs maintained?

_____ g. Who maintains the records?

_____ h. If the setting has a serial TB screening program for HCWs to test for *M. tuberculosis* infection, what are the conversion rates for the previous years?†

_____ i. Has the test conversion rate for *M. tuberculosis* infection been increasing or decreasing, or has it remained the same over the previous 5 years? (check one)

_____ Low risk
_____ Medium risk
_____ Potential ongoing transmission

Previous year _____
5 years ago _____

Year encountered _____

Date of classification _____

_____ Low risk
_____ Medium risk
_____ Potential ongoing transmission

Frequency _____

Location _____

Name _____

1 year ago _____
2 years ago _____
3 years ago _____
4 years ago _____
5 years ago _____

_____ Increasing
_____ Decreasing
_____ No change in previous 5 years

Appendix B. (Continued) Tuberculosis (TB) risk assessment worksheet

_____ j. Do any areas of the health-care setting (e.g., waiting rooms or clinics) or any group of HCWs (e.g., laboratory workers, emergency department staff, respiratory therapists, and HCWs who attend bronchoscopies) have a test conversion rate for *M. tuberculosis* infection that exceeds the health-care setting's annual average? Rate _____
If yes, list. _____

_____ k. For HCWs who have positive test results for *M. tuberculosis* infection and who leave employment at the health setting, are efforts made to communicate test results and recommend follow-up of latent TB infection treatment with the local health department or their primary physician? _____ Not applicable

4. TB Infection-Control Program

_____ a. Does the health-care setting have a written TB infection-control plan? Name _____

_____ b. Who is responsible for the infection-control program? Date _____

_____ c. When was the TB infection-control plan first written? Date _____

_____ d. When was the TB infection-control plan last reviewed or updated?

_____ e. Does the written infection-control plan need to be updated based on the timing of the previous update (i.e., >1 year, changing TB epidemiology of the community or setting, the occurrence of a TB outbreak, change in state or local TB policy, or other factors related to a change in risk for transmission of *M. tuberculosis*)?

_____ f. Does the health-care setting have an infection-control committee (or another committee with infection-control responsibilities)?

1) If yes, which groups are represented on the infection-control committee? (check all that apply)

_____ Physicians	_____ Health and safety staff
_____ Nurses	_____ Administrator
_____ Epidemiologists	_____ Risk assessment
_____ Engineers	_____ Quality control
_____ Pharmacists	_____ Others (specify)
_____ Laboratory personnel	

2) If no, what committee is responsible for infection control in the setting? Committee _____

5. Implementation of TB Infection-Control Plan Based on Review by Infection-Control Committee

_____ a. Has a person been designated to be responsible for implementing an infection-control plan in your health-care setting? If yes, list the name. Name _____

_____ b. Based on a review of the medical records, what is the average number of days for the following:

- _____ Presentation of patient until collection of specimen.
- _____ Specimen collection until receipt by laboratory.
- _____ Receipt of specimen by laboratory until smear results are provided to health-care provider.
- _____ Diagnosis until initiation of standard antituberculosis treatment.
- _____ Receipt of specimen by laboratory until culture results are provided to health-care provider.
- _____ Receipt of specimen by laboratory until drug-susceptibility results are provided to health-care provider.
- _____ Receipt of drug-susceptibility results until adjustment of antituberculosis treatment, if indicated.
- _____ Admission of patient to hospital until placement in airborne infection isolation (AII).

_____ c. Through what means (e.g., review of TST or BAMT conversion rates, patient medical records, and time analysis) are lapses in infection control recognized? Means _____

_____ d. What mechanisms are in place to correct lapses in infection control? Mechanisms _____

_____ e. Based on measurement in routine QC exercises, is the infection-control plan being properly implemented?

_____ f. Is ongoing training and education regarding TB infection-control practices provided for HCWs?

Appendix B. (Continued) Tuberculosis (TB) risk assessment worksheet

6. Laboratory Processing of TB-Related Specimens, Tests, and Results Based on Laboratory Review

- a. Which of the following tests are either conducted in-house at your health-care setting's laboratory or sent out to a reference laboratory? (check all that apply)

In-house **Sent out**

- _____ Acid-fast bacilli (AFB) smears
 _____ Culture using liquid media (e.g., Bactec and MB-BacT)
 _____ Culture using solid media
 _____ Drug-susceptibility testing
 _____ Nucleic acid amplification testing

- b. What is the usual transport time for specimens to reach the laboratory for the following tests?

AFB smears _____
 Culture using liquid media (e.g., Bactec, MB-BacT) _____
 Culture using solid media _____
 Drug-susceptibility testing _____
 Nucleic acid amplification testing _____
 Other (specify) _____

- c. Does the laboratory at your health-care setting or the reference laboratory used by your health-care setting report AFB smear results for all patients within 24 hours of receipt of specimen? What is the procedure for weekends?

7. Environmental Controls

- a. Which environmental controls are in place in your health-care setting? (check all that apply and describe)

<u>Environmental control</u>	<u>Description</u>
_____ All rooms	_____
_____ Local exhaust ventilation (enclosing devices and exterior devices)	_____
_____ General ventilation (e.g., single-pass system, recirculation system)	_____
_____ Air-cleaning methods (e.g., high efficiency particulate air [HEPA] filtration and ultraviolet germicidal irradiation [UVGI])	_____

- b. What are the actual air changes per hour (ACH) and design for various rooms in the setting?

<u>Room</u>	<u>ACH</u>	<u>Design</u>
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____

- c. Which of the following local exterior or enclosing devices such as exhaust ventilation devices are used in your health-care setting? (check all that apply)

- _____ Laboratory hoods
 _____ Booths for sputum induction
 _____ Tents or hoods for enclosing patient or procedure

- d. What general ventilation systems are used in your health-care setting? (check all that apply)

- _____ Single-pass system
 _____ Variable air volume
 _____ Constant air volume
 _____ Recirculation system
 _____ Other _____

- e. What air-cleaning methods are used in your health-care setting? (check all that apply)

<u>HEPA filtration</u>	<u>UVGI</u>
_____ Fixed room-air recirculation systems	_____ Duct irradiation
_____ Portable room-air recirculation systems	_____ Upper-air irradiation
	_____ Portable room-air cleaners

Appendix B. (Continued) Tuberculosis (TB) risk assessment worksheet

f. How many All rooms are in the health-care setting? _____

Quantity _____

g. What ventilation methods are used for All rooms? (check all that apply)

Primary (general ventilation):

___ Single-pass heating, ventilating, and air conditioning (HVAC)

___ Recirculating HVAC systems

Secondary (methods to increase equivalent ACH):

___ Fixed room recirculating units

___ HEPA filtration

___ UVGI

___ Other (specify) _____

h. Does your health-care setting employ, have access to, or collaborate with an environmental engineer (e.g., professional engineer) or other professional with appropriate expertise (e.g., certified industrial hygienist) for consultation on design specifications, installation, maintenance, and evaluation of environmental controls?

i. Are environmental controls regularly checked and maintained with results recorded in maintenance logs?

j. Is the directional airflow in All rooms checked daily when in use with smoke tubes or visual checks?

k. Are these results readily available?

l. What procedures are in place if the All room pressure is not negative?

m. Do All rooms meet the recommended pressure differential of 0.01-inch water column negative to surrounding structures?

8. Respiratory-Protection Program

a. Does your health-care setting have a written respiratory-protection program?

b. Which HCWs are included in the respiratory-protection program? (check all that apply)

___ Physicians

___ Mid-level practitioners (NPs and PAs)

___ Nurses

___ Administrators

___ Laboratory personnel

___ Contract staff

___ Construction or renovation staff

___ Service personnel

___ Janitorial staff

___ Maintenance or engineering staff

___ Transportation staff

___ Dietary staff

___ Students

___ Others (specify) _____

c. Are respirators used in this setting for HCWs working with TB patients? If yes, include manufacturer, model, and specific application (e.g., ABC model 1234 for bronchoscopy and DEF model 5678 for routine contact with infectious TB patients).

Manufacturer

Model

Specific application

d. Is annual respiratory-protection training for HCWs performed by a person with advanced training in respiratory protection?

e. Does your health-care setting provide initial fit testing for HCWs? If yes, when is it conducted?

Date _____

f. Does your health-care setting provide periodic fit testing for HCWs? If yes, when and how frequently is it conducted?

Date _____

Frequency _____

g. What method of fit testing is used?

Method _____

h. Is qualitative fit testing used?

i. Is quantitative fit testing used?

Appendix B. (Continued) Tuberculosis (TB) risk assessment worksheet

9. Reassessment of TB Risk

a. How frequently is the TB risk assessment conducted or updated in the health-care setting?

Frequency _____

b. When was the last TB risk assessment conducted?

Date _____

c. What problems were identified during the previous TB risk assessment?

- 1) _____
- 2) _____
- 3) _____
- 4) _____
- 5) _____

d. What actions were taken to address the problems identified during the previous TB risk assessment?

- 1) _____
- 2) _____
- 3) _____
- 4) _____
- 5) _____

e. Did the risk classification need to be revised as a result of the last TB risk assessment?

* If the population served by the health-care facility is not representative of the community in which the facility is located, an alternate comparison population might be appropriate.

† Test conversion rate is calculated by dividing the number of conversions among HCWs by the number of HCWs who were tested and had previous negative results during a certain period (see Supplement, Surveillance and Detection of *M. tuberculosis* Infections in Health-Care Settings).

Appendix C. Risk classifications for various health-care settings and recommended frequency of screening for *Mycobacterium tuberculosis* infection among health-care workers (HCWs)*

Risk classification[†]

Setting	Low risk	Medium risk	Potential ongoing transmission [§]
Inpatient <200 beds	<3 TB patients/year	≥3 TB patients/year	Evidence of ongoing <i>M. tuberculosis</i> transmission, regardless of setting
Inpatient ≥200 beds	<6 TB patients/year	≥6 TB patients/year	
Outpatient; and nontraditional facility-based	<3 TB patients/year	≥3 TB patients/year	
TB treatment facilities	Settings in which • persons who will be treated have been demonstrated to have latent TB infection (LTBI) and not TB disease • a system is in place to promptly detect and triage persons who have signs or symptoms of TB disease to a setting in which persons with TB disease are treated • no cough-inducing or aerosol-generating procedures are performed	Settings in which • persons with TB disease are encountered • criteria for low risk are not otherwise met	
Laboratories	Laboratories in which clinical specimens that might contain <i>M. tuberculosis</i> are not manipulated	Laboratories in which clinical specimens that might contain <i>M. tuberculosis</i> might be manipulated	

Recommendations for Screening Frequency

Baseline two-step TST or one BAMT [¶]	Yes, for all HCWs upon hire	Yes, for all HCWs upon hire	Yes, for all HCWs upon hire
Serial TST or BAMT screening of HCWs	No ^{**}	At least every 12 months ^{††}	As needed in the investigation of potential ongoing transmission ^{§§}
TST or BAMT for HCWs upon unprotected exposure to <i>M. tuberculosis</i>	Perform a contact investigation (i.e., administer one TST or BAMT as soon as possible at the time of exposure, and, if the result is negative, give a second test [TST or BAMT, whichever was used for the first test] 8–10 weeks after the end of exposure to <i>M. tuberculosis</i>) ^{¶¶}		

* The term Health-care workers (HCWs) refers to all paid and unpaid persons working in health-care settings who have the potential for exposure to *M. tuberculosis* through air space shared with persons with TB disease.

† Settings that serve communities with a high incidence of TB disease or that treat populations at high risk (e.g., those with human immunodeficiency virus infection or other immunocompromising conditions) or that treat patients with drug-resistant TB disease might need to be classified as medium risk, even if they meet the low-risk criteria.

§ A classification of potential ongoing transmission should be applied to a specific group of HCWs or to a specific area of the health-care setting in which evidence of ongoing transmission is apparent, if such a group or area can be identified. Otherwise, a classification of potential ongoing transmission should be applied to the entire setting. This classification should be temporary and warrants immediate investigation and corrective steps after a determination has been made that ongoing transmission has ceased. The setting should be reclassified as medium risk, and the recommended timeframe for this medium risk classification is at least 1 year.

¶ All HCWs upon hire should have a documented baseline two-step tuberculin skin test (TST) or one blood assay for *M. tuberculosis* (BAMT) result at each new health-care setting, even if the setting is determined to be low risk. In certain settings, a choice might be made to not perform baseline TB screening or serial TB screening for HCWs who 1) will never be in contact with or have shared air space with patients who have TB disease (e.g., telephone operators who work in a separate building from patients) or 2) will never be in contact with clinical specimens that might contain *M. tuberculosis*. Establishment of a reliable baseline result can be beneficial if subsequent screening is needed after an unexpected exposure to *M. tuberculosis*.

** HCWs in settings classified as low risk do not need to be included in the serial TB screening program.

†† The frequency of screening for infection with *M. tuberculosis* will be determined by the risk assessment for the setting and determined by the Infection Control team.

§§ During an investigation of potential ongoing transmission of *M. tuberculosis*, testing for *M. tuberculosis* infection should be performed every 8–10 weeks until a determination has been made that ongoing transmission has ceased. Then the setting should be reclassified as medium risk for at least 1 year.

¶¶ Procedures for contact investigations should not be confused with two-step TSTs, which are used for baseline TST results for newly hired HCWs.

Appendix D. Environmental controls record and evaluation*

Type of environmental control [†]	No. [§]	Location in the health-care setting [‡]	How often maintained ^{**}	How often evaluated ^{**}	Last evaluation date	Next evaluation due date

* Some settings will not be able to complete all parts of the table. List environmental controls in order of effectiveness.

† For example, ultraviolet germicidal irradiation (UVGI), high-efficiency particulate air (HEPA) filters, or airborne infection isolation (AII) room.

§ Number of UVGI units, HEPA filters, and AII rooms in each location of the health-care setting.

‡ For example, inpatient rooms, emergency departments, bronchoscopy suites, sputum induction rooms, outpatient areas, and waiting areas.

** Daily, weekly, monthly, annually, or other frequency (describe).

Appendix F. Quality control (QC) procedural observation checklists

Quality Control (QC) Procedural Observation Checklist for Placing Tuberculin Skin Tests (TSTs) — Mantoux Method

Date _____	Trainer (QC by) _____	Trainee (TST placed by) _____
------------	-----------------------	-------------------------------

Scoring: ✓ or Y = Yes X or N = No NA = Not Applicable

1. Preliminary ____ Uses appropriate hand hygiene methods before starting. ____ Screens patient for contraindications (severe adverse reactions to previous TST).[*] ____ Uses well-lit area. 2. Syringe[†] filled with exactly 0.1 mL of 5 tuberculin units (TU) purified protein derivative (PPD) antigen[‡] ____ Removes antigen vial from refrigeration and confirms that it is 5 TU PPD antigen.[§] ____ Checks label and expiration date on vial. ____ Marks opening date on multidose vial. ____ Fills immediately after vial removed from refrigeration. ____ Cleans vial stopper with antiseptic swab. ____ Twists needle onto syringe to ensure tight fit. ____ Removes needle guard. ____ Inserts needle into the vial. ____ Draws slightly over 0.1 mL of 5 TU PPD into syringe. ____ Removes excess volume or air bubbles to exactly 0.1 mL of 5 TU PPD while needle remains in vial to avoid wasting of antigen. ____ Removes needle from vial. ____ Returns antigen vial to the refrigerator immediately after filling. 3. TST administration site selected and cleaned ____ Selects upper third of forearm with palm up ≥2 inches from elbow, wrist, or other injection site.^{**} ____ Selects site free from veins, lesions, heavy hair, bruises, scars, and muscle ridge. ____ Cleans the site with antiseptic swab using circular motion from center to outside. ____ Allows site to dry thoroughly before administering antigen. 4. Needle inserted properly to administer antigen ____ Rests arm on firm, well-lit surface. ____ Stretches skin slightly.^{††}	____ Holds needle bevel-up and tip at 5°–15° angle to skin. ____ Inserts needle in first layer of skin with tip visible beneath skin. ____ Advances needle until entire bevel is under the first layer of skin. ____ Releases stretched skin. ____ Injects entire dose slowly. ____ Forms wheal, as liquid is injected. ____ Removes needle without pressing area. ____ Activates safety feature of device per manufacturer's recommendations, if applicable. ____ Places used needle and syringe immediately in puncture-resistant container without recapping needle. ____ Immediately measures wheal to ensure 6–10 mm in diameter (Actual wheal measurement _____ mm). ____ If blood or fluid is present, blots site lightly with gauze or cotton ball. ____ Discards used gauze or cotton ball according to local standard precautions. ____ If the TST is administered incorrectly (too deeply or too shallow) and the wheal is inadequate (<6 mm), a new TST should be placed immediately. Applying the second TST on the other arm or in a different area of the same arm (at least 2 inches from the first site) is preferable so that the TST result will be easier to read. ____ Documents all information required by the setting (e.g., date and time of TST placement, person who placed TST, location of injection site and lot number of tuberculin). ____ Uses appropriate hand hygiene methods after placing TST. 5. Explanation to the client regarding care instructions for the injection site ____ The wheal (bump) is normal and will remain about 10 minutes. ____ Do not touch wheal; avoid scratching. ____ Avoid pressure or bandage on injection site. ____ Rare local discomfort and irritation does not require treatment. ____ May wash with soap and water (without pressure) after 1 hour. ____ No lotions or liquids on site, except for light washing, as above. ____ Keep appointment for reading.
---	---

^{*} Severe adverse reactions to the TST are rare but include ulceration, necrosis, vesiculation, or bullae at the test site, or anaphylactic shock, which is substantially rare. These reactions are the only contraindications to having a TST administered.

[†] Use a 1/4–1/2-inch 27-gauge needle or finer, disposable tuberculin (preferably a safety-type) syringe.

[‡] Prefilling syringes is not recommended. Tuberculin is absorbed in varying amounts by glass and plastics. To minimize reduction in potency, tuberculin should be administered as soon after the syringe has been filled as possible. Following these procedures will also help avoid contamination. Test doses should always be removed from the vial under strictly aseptic conditions, and the remaining solution should remain refrigerated (not frozen). Tuberculin should be stored in the dark as much as possible and exposure to strong light should be avoided. **SOURCE:** American Thoracic Society, CDC, Infectious Disease Society of America. Diagnostic standards and classification of tuberculosis in adults and children. *Am J Respir Crit Care Med* 2000;161:1376–95.

[§] Preventing tuberculin antigen and vaccine (e.g., Td toxoid) misadministration is important. Measures should include physical separation of refrigerated products, careful visual inspection and reading of labels, preparation of PPD for patient use only at time of testing, and improved record keeping of lot numbers of antigens, vaccines, and other injectable products. **SOURCE:** CDC. Inadvertent intradermal administration of tetanus toxoid-containing vaccines instead of tuberculosis skin tests. *MMWR* 2004;53:662–4.

^{**} If neither arm is available or acceptable for testing, the back of the shoulder is a good alternate TST administration site. **SOURCE:** National Tuberculosis Controllers Association, National Tuberculosis Nurse Consultant Coalition. *Tuberculosis nursing: a comprehensive guide to patient care*. Smyrna, GA: National Tuberculosis Controllers Association; 1997.

^{††} Stretch skin by placing nondominant hand of health-care worker (HCW) on patient's forearm below the needle insertion point and then applying traction in the opposite direction of the needle insertion. Be careful not to place the nondominant hand of the HCW opposite the administration needle if the patient is likely to move during the procedure, which might cause an accidental needle-stick injury to the HCWs. In children and others who are likely to move during the procedure, certain trainers prefer stretching the skin in the opposite direction of the needle insertion by placing the nondominant hand of the HCW under the patient's forearm. This method should not be used for persons with poor skin turgor.

Appendix F. (Continued) Quality control (QC) procedural observation checklists

Quality Control (QC) Procedural Observation Checklist for Reading Tuberculin Skin Test (TST) Results — Palpation Method		
Date _____	Trainer (QC by) _____	Trainee (TST placed by) _____
Scoring: ✓ or Y = Yes X or N = No NA = Not Applicable		
1. Preliminary _____ Uses appropriate hand hygiene methods before starting. _____ Keeps fingernails shorter than fingertips to avoid misreading TST result. _____ Keeps TST reading materials at hand (eyeliner pencil or ballpoint pen,* and ruler). _____ Uses well-lit area. _____ Inspects for the site of the injection.	_____ Marks dots transverse (perpendicular) to long axis of forearm.	4. Placing and reading ruler _____ Places the "0" ruler line inside the edge of the left dot. Reads the ruler line inside right dot edge (uses lower measurement if between two gradations on millimeter scale) (Figure 1). _____ Uses appropriate hand hygiene methods after reading TST result.
2. Palpate — finding margin ridges (if any) _____ Palpates with arm bent at elbow at a 90° angle. _____ Lightly sweeps 2-inch diameter from injection site in four directions. _____ Uses zigzag featherlike touch. _____ Repeats palpation with arm bent at elbow at a 45° angle to determine presence or absence of induration.	5. Documenting results _____ Records all TST results in millimeters, even those classified as negative. Does not record only as "positive" or "negative." Records the absence of induration as "0 mm." _____ Correctly records results in mm; only a single measured induration in mm should be recorded. Trainee's measurement _____ mm. Trainer's (gold standard) measurement _____ mm. Trainee's result within 2 mm of gold standard reading? [§] Yes _____ No _____	NOTE: In rare instances, the reaction might be severe (vesiculation, ulceration, or necrosis of the skin). Report severe adverse events to the FDA MedWatch Adverse Events Reporting System (AERS), telephone: 800-FDA-1088; fax: 800-FDA-0178; http://www.fda.gov/medwatch report form 3500, Physicians' Desk Reference.
If induration is present, continue with these steps[†]:		
3. Placing marks _____ Holds palm over injection site. _____ Cleanse site with antiseptic swab using circular motion from center to outside. _____ Uses fingertips to find margins of the induration. _____ Marks the induration by placing small dots on both sides of the induration. _____ Inspects dots, repeats finger movements toward indurated margin, and adjusts dots if needed.	NOTE: In rare instances, the reaction might be severe (vesiculation, ulceration, or necrosis of the skin). Report severe adverse events to the FDA MedWatch Adverse Events Reporting System (AERS), telephone: 800-FDA-1088; fax: 800-FDA-0178; http://www.fda.gov/medwatch report form 3500, Physicians' Desk Reference.	
* A fine-tipped eyeliner pencil or ballpoint pen can be used as a marker. An eyeliner pencil is useful for TST training and for blinded independent duplicate readings (BIDRs) because the dots are easy to remove with a dot of lubricant (e.g., baby oil). Alternative TST result reading methods have been described, including the pen method.		
† If induration is not present, record the TST result as 0 mm and go to the end of this form (Documenting results).		
§ For example, if the TST trainer reads the TST result (the gold standard reading) as 11 mm, the trainee's TST reading should be between 9–13 mm to be considered correct.		

Appendix G. Model framework for medical evaluation request and questionnaire for users of N95 disposable respirators

Medical Evaluation Request		Yes	No
1. Today's date _____		_____	_____
2. Your name _____		_____	_____
3. Your age (to nearest year) _____		_____	_____
4. Sex _____ Male _____ Female _____		_____	_____
5. Your height _____ feet _____ inches _____		_____	_____
6. Your weight _____ pounds _____		_____	_____
7. Your job title _____		_____	_____
8. A phone number where you can be reached by the health-care professional who reviews this questionnaire (include area code) _____		_____	_____
9. The best time to phone you at this number _____		_____	_____
10. Has your employer told you how to contact the health-care professional who will review this questionnaire? _____ Yes _____ No _____		_____	_____
11. Check the type of respirator you will use (check all that apply)			
_____ N-, R-, or P-disposable respirator (filter-mask, noncartridge type only)		_____	_____
_____ Half-facepiece type		_____	_____
_____ Full-facepiece type		_____	_____
_____ Powered air-purifying respirator (PAPR) – tight-fitting		_____	_____
_____ PAPR – loose-fitting		_____	_____
_____ Other type (supplied-air or self-contained breathing apparatus)		_____	_____
12. Have you worn a respirator? _____ Yes _____ No _____		_____	_____
If "yes," what types? _____		_____	_____
Yes No	Questionnaire for Users of N95 Respirators		
_____	1. Do you currently or have you smoked tobacco during the previous month? If "yes"	_____	_____
_____	a. At what age did you start smoking? _____	_____	_____
_____	b. How long ago did you quit smoking? _____	_____	_____
_____	c. How many packs per day did or do you smoke? _____	_____	_____
_____	2. Have you ever had any of the following conditions?		
_____	a. Seizures (fits)	_____	_____
_____	b. Diabetes (sugar disease)	_____	_____
_____	c. Allergic reactions that interfere with your breathing	_____	_____
_____	d. Claustrophobia (fear of closed-in places)	_____	_____
_____	e. Trouble smelling odors	_____	_____
_____	3. Have you ever had any of the following pulmonary or lung problems?		
_____	a. Asbestosis	_____	_____
_____	b. Asthma	_____	_____
_____	c. Chronic bronchitis	_____	_____
_____	d. Emphysema	_____	_____
_____	e. Pneumonia	_____	_____

_____	h. Pneumothorax (collapsed lung)	_____	_____
_____	i. Lung cancer	_____	_____
_____	j. Broken ribs	_____	_____
_____	k. Any chest injuries or surgeries	_____	_____
_____	l. Any other lung problem that you have been told about	_____	_____
_____	4. Do you currently have any of the following symptoms of pulmonary or lung illness?		
_____	a. Shortness of breath	_____	_____
_____	b. Shortness of breath when walking quickly on level ground or walking up a slight hill or incline	_____	_____
_____	c. Shortness of breath when walking with other people at an ordinary pace on level ground	_____	_____
_____	d. Have to stop for breath when walking at your own pace on level ground	_____	_____
_____	e. Shortness of breath when washing or dressing yourself	_____	_____
	4. (Continued)		
	i. Shortness of breath that interferes with your job	_____	_____
	g. Coughing that produces phlegm (thick sputum)	_____	_____
	h. Coughing that wakes you early in the morning	_____	_____
	i. Coughing that occurs primarily when you are lying down	_____	_____
	j. Coughing up blood in the last month	_____	_____
	k. Wheezing	_____	_____
	l. Wheezing that interferes with your job	_____	_____
	m. Chest pain when you breathe deeply	_____	_____
	n. Any other symptoms that you think might be related to lung problems	_____	_____
	5. Have you ever had any of the following cardiovascular or heart problems?		
	a. Heart attack	_____	_____
	b. Stroke	_____	_____
	c. Angina	_____	_____
	d. Heart failure	_____	_____
	e. Swelling in your legs or feet (not caused by walking)	_____	_____
	f. Heart arrhythmia (heart beating irregularly)	_____	_____
	g. High blood pressure	_____	_____
	h. Any other heart problem that you have been told about	_____	_____
	6. Have you ever had any of the following cardiovascular or heart symptoms?		
	a. Frequent pain or tightness in your chest	_____	_____
	b. Pain or tightness in your chest during physical activity	_____	_____
	c. Pain or tightness in your chest that interferes with your job	_____	_____
	d. In the previous 2 years, have you noticed your heart skipping or missing a beat?	_____	_____
	e. Heartburn or indigestion that is not related to eating	_____	_____
	f. Any other symptoms that you think might be related to heart or circulation problems	_____	_____
	7. Do you currently take medication for any of the following problems?		
	a. Breathing or lung problems	_____	_____
	b. Heart trouble	_____	_____
	c. Blood pressure	_____	_____
	d. Seizures (fits)	_____	_____
	8. If you have used a respirator, have you ever had any of the following problems? (If you have never used a respirator, check here _____ and go to question 9.)		
	a. Eye irritation	_____	_____
	b. Skin allergies or rashes	_____	_____
	c. Anxiety	_____	_____
	d. General weakness or fatigue	_____	_____
	e. Any other problem that interferes with your use of a respirator	_____	_____
	9. Are you currently taking any medications? If yes, list here _____		
	10. Would you like to talk with the health-care professional who will review this questionnaire about your answers to this questionnaire?	_____	_____
	Please explain "yes" answers (use back of form if necessary)	_____	_____

Bone marrow transplant unit

Decontamination

Healthcare environment

Immunosuppression

Ventilation

Water

ABSTRACT

Background: Patients undergoing bone marrow transplantation or chemotherapy for cancer are profoundly immunosuppressed. They are at risk for both endogenous and exogenous infections and require enhanced protection from infection while in hospital.

Objectives: The aim of this narrative review was to determine the optimal design features of bone marrow transplant (BMT) units for reducing infection risk in these vulnerable patients.

Sources: A literature search was performed on PubMed and other databases for documents published between January 2000 and October 2021. Keywords were: bone marrow transplant unit OR hematopoietic stem cell transplant unit OR haematology unit OR haemato-oncology unit AND design OR design guidelines OR design criteria OR ventilation specification OR HEPA filtration OR water outbreaks OR water system design.

Content: Guidelines and other papers pertaining to BMT unit design are discussed. Key design features identified from the literature to reduce infection risks include high efficiency particulate air filtration, positive-pressure ventilation, sufficient air changes and sealed rooms. The evidence for each of these parameters and other findings are discussed. We found no guidelines specific to water quality and control in BMT units.

Implications: Guidelines on the various components of design were found, but no comprehensive guidance documents addressing all relevant aspects, such as ventilation, water, and other design features, were found. Literary publications and policy documents were combined and summarised to highlight key design features aimed at reducing infection risk in this vulnerable patient group. We propose the development of international guidance for the design of BMT units encompassing all components. **T. Inkster, Clin Microbiol Infect 2022;28:1091**

Introduction

Patients undergoing bone marrow transplantation (BMT) or intensive chemotherapy regimens for blood cancers are profoundly immunosuppressed and have multiple risk factors for infection [1,2]. Damage to mucosal surfaces, impaired barrier defences, pancytopenia, and impaired cell-mediated and humoral immunity occur as a result of treatment [1]. Patients are at risk for endogenous infection as well as pathogens from the surrounding environment, especially those from air, water, equipment, and surfaces [1,3]. Environmental organisms of little consequence to healthy

humans can pose a significant threat to transplant recipients [4–16]. Safe design of the patients' environment with expert input is therefore crucial to minimize exposure to ubiquitous pathogens from environmental sources. This paper aims to summarize existing recommendations using specifications developed from amalgamating related documents, supported by design criteria from international and literary sources.

Existing guidelines for bone marrow transplant units

Search strategy

A narrative review was performed using relevant search terms: bone marrow transplant unit OR hematopoietic stem cell transplant unit OR haematology unit OR haemato-oncology unit AND

design OR design guidelines OR design criteria OR ventilation specification OR HEPA filtration OR water outbreaks OR water system design. The databases employed were PubMed, CINAHL, CDSR, DARE and EMBASE from “Jan 2000 to Oct 2021” for guidelines, reviews, and original articles detailing recommendations for BMT facilities and/or outbreaks linked with transplant (and other immunosuppressed) patients. Relevant documents were scanned before exclusion, along with non-English papers, posters, and conference reports. Hospital types, study ward/unit, study length and size, outbreak pathogen, environmental involvement, infection control interventions, and other variables that might have an impact on the results were noted. Published data were checked for additional references and duplicate publication.

Findings

There are no bespoke guidelines for the design of BMT units incorporating all of ventilation, water, layout, and other key aspects of design of the built environment. Relevant guidance may be extracted from various technical and building documents.

International guidelines for preventing infections in BMT patients were published in 2009 by multiple agencies [17]. This multiagency publication delineates 10 global recommendations relevant to hospital design and ventilation for BMT patients [17]. A subsequent survey in 2018 revealed that the majority of respondents were unable to demonstrate that these recommendations had been implemented, with only one centre meeting all requirements [18]. In 2017, Crysandt et al. also highlighted the lack of standards for BMT unit infrastructure and commented on the variation of facilities [19]. They observed that local aspects dominated the decisions with regards to the technical specification of such units [19]. Throughout all documents reviewed, the key design features specified for a BMT unit are sealed rooms with high efficiency particulate air (HEPA) filtration, high air changes, and positive-pressure ventilation [1,17,20–26]. Anterooms are optional features but are required when BMT patients are isolated for airborne infections [23]. Given the lack of detail on BMT unit design, we propose additional recommendations for protective ventilation as follows, including risk management of water sources and a number of other relevant design features highlighted during this review.

Ventilation

HEPA filtration

Guidance documents from various countries recommend HEPA filtration [1,17,20–26]. The purpose of HEPA filtration is primarily to remove airborne particles from the room air supply. This is because it may include fungal spores as well as other contaminants from external air sources. The HEPA filtration stage can be incorporated into the air handling unit, such that all the air supplied to the BMT unit is filtered or at points of discharge into specific rooms. HEPA filters are tested at each filter's most penetrating particle size, normally around 0.2–0.4 microns because fungal spores are around 10 times larger. Each HEPA filter should also be tested on installation to verify that there are no gaps around the mounting through which air can bypass filtration. According to the European standard, there are various HEPA filter classifications, with effectiveness stated as between 99.95% and 99.999% for 0.3 micron particles [27]. Although some bodies have recommended specific grades of HEPA filter, there is probably little practical difference, even though the choice of HEPA has an impact on the performance and energy demands of an air handling unit.

Several studies support the use of HEPA filtration to protect BMT and leukaemic patients [28–32]. One paper reports the risk of hospital acquired aspergillosis as being tenfold greater in BMT

patients when not accommodated in a HEPA-filtered environment [28]. No cases were identified among 39 BMT patients accommodated in a HEPA-filtered room versus 14 cases in 74 BMT patients who were housed elsewhere [28]. Despite a range of control measures implemented in one haematology unit, cases of *Aspergillus* continued to occur. Introduction of HEPA filtration reduced the number of cases to zero with a subsequent reduction in diagnostic procedures and use of amphotericin B [29].

In another outbreak, 10 haematology patients developed invasive aspergillosis over a 6-month period [30]. After high counts of *Aspergillus* spores were detected in the air, HEPA filters were installed. Subsequently, only two patients developed invasive fungal infection – in the two years following the outbreak [30]. In the United States, HEPA filtration was installed in a newly constructed hospital in response to an increase in the number of patients with immunosuppression. Efficacy of the filtration system was demonstrated with air sampling markedly reducing *Aspergillus* spore counts to 0–0.7 cfu/m³ [31].

Ideally, a BMT suite should be supplied using HEPA-filtered air, including the corridor and supporting service areas such as prep and treatment rooms. In one study, invasive fungal infection cases were thought to be due to patients leaving their HEPA-filtered rooms for short periods; this exposed them to ingress of spores due to personnel entering the room from a non-HEPA-filtered corridor [32]. HEPA filtration in the BMT suite allows for patient movement outside the room and gives added protection to the patient when the room doors are opened.

Positive pressure (protective isolation)

Guidance documents reviewed recommend positive pressure but to varying degrees. Some documents stipulate a positive pressure of ten pascals [1,17,20–26]. Others do not specify the degree of positive pressure required [25,26]. BMT infection guidelines from the United States also highlight the importance of airflow direction, continuous pressure monitoring, and self-closing doors to maintain constant pressure differentials [22]. Positive pressure without HEPA-filtered air is unlikely to provide sufficient protection from fungal spores. The protective ventilation strategy aims to supply an excess of HEPA-filtered air into a room, and surplus air should leak outward through the inevitable gaps in the room's integrity (such as around and under door/windows and via cable conduits and integrated plumbing system panels). This outward airflow prevents unfiltered air in adjacent spaces from travelling into the room. Some guidance documents recommend a positive pressure of 10 Pa, which may help to reduce the risk of invasive fungal infection in the absence of corridor HEPA filtration [33]. The importance of positive air pressure may be seen from outbreak reports, particularly those with an identified source of fungal spores. While investigating 21 confirmed cases of invasive fungal infection among leukaemia and BMT patients, it was found that the pressure in the unit was negative relative to an adjacent building site. The assumption is that construction work led to dispersal of *Aspergillus* spp. spores, which entered the unit due to this pressure differential [4].

Air changes

Air changes per hour (ACHs) are a measure of how many times the air within the patient's room is replaced each hour. Air change rates serve three main functions (a) thermal comfort for the patient (b) odour control, and (c) dilution of infectious particles. The air change rate for BMT patient rooms and other rooms within the unit should therefore provide both comfort and safety. Vulnerable patients are protected from dilution of any airborne pathogens as well as aerosolised medication. Sufficient air change rates, specifically

for bathrooms, facilitate drying and aid the removal of excess humidity that might otherwise encourage fungal growth [34].

Computational fluid dynamic analysis concludes that six ACHs are the minimal rates required for patient comfort [35,36]. This is particularly important in the BMT setting because patients are isolated in rooms for a prolonged period. Applying the Wells-Riley equation means that increasing the volume of clean air in a patient room will expose the patient to fewer infectious particles [37]. There is a relationship between air changes and pathogen transmission with respect to airborne infections. At the present time, however, there are few studies and insufficient data to support minimal air change requirements [36]. The purpose of air changes in the protective isolation setting should be dilution and removal of infectious particles within the room. As such, recommended air change rates vary between guidance documents, with 10, greater or equal to 12, and 15 ACHs all being cited [1,17,20–26].

Sealing of rooms and corridor air

Bedrooms and en-suite walls, ceilings, and any maintenance access panels should be sealed. Adequate sealing ensures pressure differentials can be maintained and avoids ingress of unfiltered air into the room [17,20,21]. This includes sealing of all room services, such as electrical points, ceiling hatches, and sink panels. Permeability testing is recommended on initial validation and following any subsequent breach in integrity [38].

Not all documents recommend HEPA filtration of the ward corridor. To mitigate risk from the corridor, staff could potentially operate a door closing policy. This ensures that a drop in positive pressure when opening a door does not fall sufficiently to allow ingress of contaminated air from the corridor. Automatic door closures with a visual digital readout of pressure and an alarm at the nurses' station would be desirable.

Although an air lock entrance to the ward is not specified for neutropaenic wards, it functions as an additional measure to prevent ingress of air into the unit [17,20]. This is particularly important if a corridor has no HEPA-filtered air supply (apart from air spilling from the rooms themselves) and there are no patient anterooms.

Traditionally, anterooms are for donning and doffing of personal protective equipment and are not a requirement for protective isolation purposes. They are, however, likely to offer extra protection when accommodating immunosuppressed patients with airborne infections. This area is currently omitted from some guidance documents, but it features in those from the United States, with a recommendation for patients to be placed in a positive-pressure bedroom with a negative-pressure anteroom [23]. Patients with airborne infections in a positive-pressure room represent a serious risk to corridor traffic, which might include recovering patients, staff, and visitors.

BMT patients are known to be at increased risk for COVID-19 infection. It is unclear at this stage what role the ward environment has in prevention of COVID-19 infection in this vulnerable group. It is possible that, despite rigorous environmental control measures, patients may acquire infections from staff or visitors who are asymptomatic. Units that are designed with negative pressure anterooms may afford more protection. Table 1 summarises the ventilation requirements for a bone marrow transplant unit.

Monitoring of air quality

There is a lack of consensus in the literature regarding fungal air counts in BMT units along with variation in sampling methods [39]. Air sampling is performed on a monthly basis in the authors' own unit as a quality assurance check. If implementing a routine air

sampling policy, the pitfalls of air sampling and the factors that can influence results should be considered [40–46].

Water

Water control and monitoring

Immunosuppressed patients are at risk for waterborne pathogens such as *Ps. aeruginosa*, *Legionella* spp., other gram-negative bacteria, fungi, and atypical mycobacteria [5,9,47–52]. For this reason, control measures for water should be considered at the time of planning the unit. Outlets should be selected carefully. Tap components linked to *Pseudomonas* outbreaks have been reported since 1966, and flow straighteners have been linked with subsequent outbreaks [53,54]. Sinks should be designed with minimal splash in mind, and it has been suggested that sinks be located at least two metres from patients to minimise splash risk [55]. Little used outlets should be regularly surveyed and removed [54]. Flushing regimens should be incorporated into daily ward procedures to prevent stagnation, with regular maintenance programmes implemented for taps, tap filters, and other outlets.

Water testing for *Legionella* spp., *Ps. aeruginosa* and atypical mycobacteria is recommended before patients enter the unit and at regular intervals thereafter to demonstrate control. Should outbreaks of waterborne pathogens occur, accounts from published outbreaks contain detail on successful control measures. These include (a) avoidance of tap/shower water, (b) application of point-of-use filters, (c) replacement programme for showerheads and regular cleaning/disinfection, (d) cleaning and disinfection of storage tanks, (e) treatment of water system with biocides, (e) cleaning and thorough drying of infusion trays, and (f) protection of CVCs during showering/bathing [49,52,54,56–60].

Patient bathrooms

Patient bathrooms and associated plumbing represent a potential source of mould [34]. Surface finishes should be of a high standard with use of water-resistant products. Ongoing staff education is required for timely reporting of damage to en-suite flooring, shower areas, etc. to enable rapid repair and prevent buildup of mould. After 72 hours, the likelihood of fungal growth increases. In such high-risk units' disposable components such as showerheads may be desirable.

Other water sources

Other water sources, such as ice machines and water coolers, should not be installed in a BMT unit because they have frequently been associated with microbial contamination [61,62]. Air conditioning units have been linked to fungal contamination and should be avoided. If these are present, they should be regularly serviced, tested, and maintained [62,63]. Dishwashers have been shown to harbour pathogenic fungi such as *Aspergillus*, *Fusarium*, and *Exophiala* spp [64].

Energy efficiency

New technologies that promote energy efficiency are becoming a feature of new hospitals. Guidance recommends that energy efficiency methods, such as chilled beams for ventilation purposes, should not be installed in high-risk units [21]. Desired air changes for a BMT unit are unlikely to be achievable using this technology. Chilled beams involve a water source and can be prone to condensation, which along with potential accumulation of dust both poses a risk to immunosuppressed patients [65].

Table 1
Ventilation criteria for a bone marrow transplant unit

Recommendation	Rationale	References
All air entering the bedrooms must be HEPA filtered (minimum H13 [E12]) and located within the supply air diffuser (i.e., corridor and room air should be HEPA filtered).	External air carries fungal spores, and ducting may also become a source of fungus if not maintained or if there is any breach in the ducting or condensation/water ingress creating conditions for mould growth. Point-of-supply filtration ensures air entry into breathing space is in the cleanest state when supplied. Corridor air will ingress even into positive-pressured rooms when the door opens; increased filtration into the corridor space ensures a further level of protection. Patients will often need to travel along corridors and HEPA filtration ensures a degree of freedom during recovery phases.	[17,20–22,25,26,29]
Rooms should be positively pressurized to 10 pascals.	This robustly prevents ingress of unfiltered air into the patient room through all of the tiny gaps in the integrity of the room through which air can move depending on pressure differentials across the building, which can change with external factors such as wind direction and temperatures.	[17,20–22]
The minimum number of air changes at 10 ACHs should be achieved.	This ensures rapid dilution and removal of within room contamination (e.g., for airborne respiratory virus such as COVID; airborne bacteria such as those from water outlet aerosolisation, as well as any fungal spore ingress). Higher ACH can risk drafts and thermal discomfort.	[17,20–22,25,26]
Bedrooms and en-suite walls, ceilings, and any maintenance access panels should be sealed.	This ensures pressure differential can be maintained and avoids ingress of unfiltered air into the room.	[20–22,38]
All room services must be sealed (e.g., electrical points, ceiling hatches, sink panels).	As above.	[20–22,38]
Chilled beams should be avoided.	Condensation can occur on the chilled beam and promote damp conditions. Dirt can accumulate on the beam due to re-entrainment, and cleaning becomes a logistical issue when the beds are in use. Chilled beams involve a water source in the patient environment, so they introduce a potential biohazard in case of leaks (e.g., legionella and pseudomonas).	[65]
Avoid hatches placed in rooms that require regular access for maintenance of services.	Every breach in the seal of the room (such as ceiling voids and walls) requires the room to be resealed and tested to ensure that unfiltered air does not ingress into the room. Access to rooms for service work will mean the room needs to be emptied on a regular basis because work cannot take place when a high-risk patient is in the room due to risk of fungal spore ingress.	AR
A continuous pressure monitoring system with an automated alarm system should be installed for each room. Monitoring should be done with local digital readouts and central building management systems.	Alarms will give an early indication of a pressure drop and allow for risk assessment and moving of the patient, if required	[17,21,24,25]
Treatment, preparation rooms and supply stores should be HEPA filtered.	Reduction of bioburden in spaces where IVs are prepared is important for sterile field.	AR
Backup air handling unit should be fitted or detailed contingency plan if only a single AHU is present.	In the event of a failure and a patient <i>in situ</i> , there is usually no ability to reverse immune compromise and so the accommodation needs continuity of care ensured in event of failures.	AR
Ensure double-door entry system with a corridor airlock.	This provides additional protection from ingress of outside air.	AR
Ensure the whole system is commissioned and verified prior to being put into use. The results for the commissioning and verification should be signed off by all parties and all documentation recorded in the operating and maintenance manual.	When a unit is occupied, it is very difficult to rectify faults because the clinical needs are immediate.	[20,21]
Allowance should be made for annual verification of the system.	Service planning with careful coordination with the clinical teams is required to ensure access for verification is not denied. AHU failures in non-maintained systems will pose an immediate issue for high-risk patients.	[20,21,26]

HEPA, high efficiency particulate air; ACH, air changes/hour; AHU, air handling unit; AR, author recommendation.

Discussion

Given the vulnerabilities of the immunocompromised patient population, it seems that their accommodation in today's hospitals would benefit from more stringent guidance. Most documents reviewed recommended BMT units have HEPA-filtered patient rooms, with high air changes and positive pressure. However, not all recommend units have HEPA filtration in corridors.

With relation to water, there is no specific guidance document for water quality and control in BMT units. Outbreaks in BMT units have been described in the scientific literature in relation to *Legionella* spp., fungi, *Pseudomonas* spp., atypical mycobacteria and other Gram-negative bacteria such as *S. maltophilia* [9,10,47,50,51]. Evidence exists as to outlets, sinks, showers, and drains all being implicated in such outbreaks [9,10,66].

Guidance documents also omit detail in relation to other BMT ward areas such as treatment and preparation rooms. These BMT facilities might differ from the other wards in that, ideally, they should also be HEPA filtered. Patient bathrooms are frequently conducive to growth of mould [34], and guidance on how to mitigate the risks associated with this issue would be beneficial.

In conclusion, there is a notable absence of bespoke guidance for design and ventilation/water standards for BMT units. We combined findings from international guidance documents and published literature on outbreaks/incidents. We propose the development of international guidance for BMT units, which goes beyond ventilation specification to incorporate other environmental risks and provides overarching detail on ward design as a whole.

AN EVALUATION OF HOSPITAL SPECIAL-VENTILATION-ROOM PRESSURES

Nancy Rice, MPH; Andrew Streifel, MPH; Donald Vesley, PhD

ABSTRACT

OBJECTIVE: To quantitate the magnitude and consistency of positive (airflow out) and negative (airflow in) hospital special-ventilation-room (SVR) airflow.

DESIGN: A room-pressure evaluation was conducted during two seasons on a total of 18 rooms: standard rooms, airborne infection isolation rooms, and protective environment rooms. The pressures were measured using a digital pressure gauge-piezoresistive pressure sensor that measured pressure differentials. With doors closed, the rooms were measured a minimum of 30 times each for a cooling season and a heating season.

RESULTS: The standard rooms showed the least amount of variability in pressure differential, with an average of -0.2 Pa (median, -0.2 Pa), and an interquartile range (IQR) of 0.4 Pa. Airborne infection isolation rooms showed more variability in

pressure, with an average of -0.3 Pa (median, -0.2 Pa) and an IQR of 0.5 Pa. Protective environment rooms had the greatest fluctuation in pressure, with an average of 8.3 Pa (median, 7.7 Pa) and an IQR of 8.8 Pa. Dramatic pressure changes were observed during this evaluation, which may have been influenced by room architectural differences (sealed vs unsealed); heating, ventilation, and air-conditioning zone interactions; and stack effect.

CONCLUSION: The pressure variations noted in this study, which potentially affect containment or exclusion of contaminants, support the need for standardization of pressure requirements for SVRs. To maintain consistent pressure levels, creating an airtight seal and continuous pressure monitoring may be necessary (*Infect Control Hosp Epidemiol* 2001;22:19-23).

Pressurization controls for hospital ventilation systems play an important part in protecting employees and patients from airborne infection hazards. When these systems fail, disease outbreaks can result. An example of this occurred in 1991 in a New York hospital, where a highly infectious patient with multiple drug-resistant tuberculosis was housed in hospital rooms equipped with improperly functioning ventilation controls. Three patients and one correctional officer who were in the hospital at the time developed active multiple drug-resistant tuberculosis; two patients and the correctional officer died.¹

Another study of airborne-infection (AI) rooms in seven midwestern hospitals showed that nearly one half of the isolation rooms had air flowing in the wrong direction.² Instances like these underscore the need to ensure that ventilation systems are working properly.

In this survey, three room types at the University of Minnesota Hospital were monitored for pressure stability from June to August and September to December 1996, which allowed room pressurization to be observed under a variety of weather conditions. One room type, the standard patient room, was not designed to be under any particular pressurization. These rooms were constructed according to 1981 Guidelines for Minimum Requirements for Construction and Equipment in Hospitals.³ The second room type, the AI isolation room, was designed to be under

negative pressure in order to contain infectious agents. The third room type, the protective-environment room (PR), was designed to be under positive pressure to prevent airborne contaminants from entering the room.⁴

Given the degree of ventilation control on each room type, it was expected that the PR and AI rooms included in this study would hold pressure at fairly constant levels for the duration of the observation periods, while the standard rooms would show frequent fluctuations in pressure. The objective of this project was to determine which, if any, of the rooms would fluctuate in pressure, and to attempt to identify possible reasons for any large fluctuations that did occur.

METHODS

Room-pressure measurements took place on the fourth, fifth, and sixth floors in the northeastern wing of the eight-story hospital building.

The studied floors of the northeastern wing of the hospital had a total of 12 rooms, with 4 rooms on each of three sides of the wing (Figure 1). The fourth, fifth, and sixth floors all had 2 AI rooms, which were located on the northwest and southeast corners of each floor.

On the fourth floor, all of the patient rooms in the northeastern wing functioned as PR for bone marrow transplant patients. Two rooms on this floor, PR 4a and PR 4f,

FIGURE 1. Location of the sampled rooms in the northwest wing of the hospital. The sampled rooms were located on the fourth, fifth, and sixth floors of the wing.

were intended to serve patients requiring both infectious and protective isolation. These two protective-infectious isolation rooms had anterooms, while the other PR did not have anterooms. The patient rooms on this floor were designed with constant air-volume ventilation systems, which provide a consistent airflow rate to an area, with temperatures being altered as needed for thermal control. The hallways were designed with a variable air-volume system, which maintains temperature at a constant level while altering the airflow rates to an area for thermal control.

On both the fifth and sixth floors of the northeastern wing, there were 10 standard rooms (with no special ventilation control) and 2 AI rooms with anterooms. As on the fourth floor, the patient rooms had a constant air-volume ventilation system, while the hallways were designed with a variable air-volume ventilation system.

A total of 18 rooms were sampled for this project, with 6 arbitrarily selected rooms sampled on each of the fourth, fifth, and sixth floors. The sampled rooms were selected so that they would be located directly above or below sampled rooms of another floor, in a column configuration (Figure 1). This helped to ensure that the rooms on different floors would be subjected to approximately the same environmental conditions occurring outside of the building, such as wind and temperature. The 2 AI rooms were included in the sample of each floor. The other 4 rooms on each floor were chosen to include 2 adjacent rooms in the northeast corner of the hospital wing, and 2 non-adjacent rooms located in each row of 4 rooms on the northeast and southeast side of the hospital wing.

Pressure readings were taken three times per week in the early afternoon to obtain representation of room pressures at approximately the same time each sampling day. Rooms were sampled in approximately the same order

each time, with alterations made when activities in a particular room prevented immediate sampling. Occasionally, it was necessary to omit a room for 1 sampling day, due to nurses' request or circumstances that prevented closing the door to the patient rooms.

The first group of readings was collected from June 5 to August 16, 1996, with 32 sets of measurements obtained. The second group was collected from September 25 to December 20, 1996, with 37 sets of measurements obtained during this time period.

Pressure differentials were measured in Pascals ([Pa] $0.25 \text{ Pa} = 0.001 \text{ in water gauge [wg]}$) with a Minneapolis Digital Pressure and Fan Flow Gauge (Energy Conservatory, Bloomington, MN). This self-calibrating instrument had a sensitivity to 0.1 Pa (0.0004 in wg). The probe to this instrument was positioned under the closed door for sampling. Samples for both the rooms and anterooms always were taken from the hallway side of the door. For consistency, the probe was placed under the closed door about 20 cm from the hinged side of the door, perpendicular to the plane of the door frame. In the event of an unplanned door opening, rooms were allowed time for pressure stabilization after the door was reclosed before data were recorded. Each sample consisted of 12 consecutive 5-second readings, which were averaged and recorded as the pressure differential for the room on that day.

Windows and bathroom-door positions were not considered variables in this project, as the windows were locked and sealed and the bathroom doors were underfoot to allow for unrestricted airflow.

Weather variables were analyzed using multiple linear regression, with room pressure as the dependent variable and weather values, centered around their means, as the independent variables. Dummy variables were used to indicate wind direction (N, NE, E, SE, S, SW, W, or NW), with "1" coded to signify wind from a particular direction and "0" if the wind was not from that direction.

RESULTS

The data collected for this project showed that the pressure stability of the rooms varied by room type (see Table).

Standard Rooms

Standard rooms (5a to 6d) were the most stable of the three room types, with an overall mean pressure of -0.2 Pa (median, -0.2 Pa) and an interquartile range (IQR) of 0.4 Pa (see Table; as a point of reference, $-0.25 \text{ Pa} = -0.001 \text{ in of water}$, which is the 1994 Centers for Disease Control and Prevention [CDC] recommendation for AI isolation room pressure⁵). There were small fluctuations in pressure in most of the standard rooms of about $\pm 0.4 \text{ Pa}$, but the standard rooms usually had consistently weak positive ($0 \leq x \leq 1.0 \text{ Pa}$) or weak negative ($0 \geq -x \geq -1.0 \text{ Pa}$) pressure differentials throughout the sampling period. This consistency in pressure of the standard rooms would result in consistency of direction of airflow in these rooms.

TABLE
SUMMARY STATISTICS FOR ALL ROOM TYPES

Room Type	Readings	Mean Pressure (Pa)*	Median Pressure (Pa)	Interquartile Range† (Pa)	Minimum Pressure (Pa)	Maximum Pressure (Pa)	Range (Pa)
Standard room	533	-0.2‡	-0.2	0.4	-1.4	0.8	2.2
Airborne infection isolation room	274	-0.3	-0.2	0.5	-1.3	0.7	2.0
Protective environment room	551	8.3	7.7	8.8	-1.1	21.7	22.8

Abbreviation: Pa, Pascal.

* 0.25 Pa = 0.1 in. of water.

† Interquartile range = Q1-Q3, where Q1 is the median of observations below the median and Q3 is the median of observations above the median.

‡ Negative numbers indicate negative pressure (airflow into the room).

Infectious Isolation Rooms

The four AI (AI 5a to AI 6b) rooms showed more pressure fluctuation than the standard rooms, with an average pressure of -0.3 Pa (median, -0.2 Pa) and an IQR of 0.5 Pa (see Table). Unlike the standard rooms, where some rooms had consistently positive pressure and some rooms had consistently negative pressure, most of the AI rooms and their accompanying anterooms had an overall negative pressure differential, as intended. Of the 274 total sample readings taken of AI rooms, there were only 10 readings (3.6%) where both the anteroom and the patient room of an AI room had slightly positive (0.1 Pa) or neutral (0 Pa) pressure differentials. However, the magnitude of the negative pressure differentials varied over time. Adequate negative pressure, as suggested by the CDC, is -0.25 Pa (-0.001 in wg).⁵ Of the 274 pressure readings for AI rooms, 186 (68%) of the readings showed compliance with the CDC recommendations.

Air-balance data obtained from maintenance and operation records for these rooms showed that the rooms all had appropriate numbers of air changes per hour (ACH). All sampled isolation rooms had greater than the minimum of 6 ACH required by the CDC, but less than the 12 ACH that the CDC recommends. Although only one room, AI 6a, met the CDC recommendations that air be exhausted from the room at a rate of 10%, or 50 cubic feet per minute (cfm), greater than air supplied, two rooms were within 5 cfm of this requirement and the other was within 15 cfm.

Protective Isolation Rooms

The pressure differentials of the six PR (PR 4a to PR 4f) were much stronger than the AI rooms or the standard rooms (see Table). The PR pressure differentials also fluctuated to a much greater degree than the other two types of rooms. The average pressure for the PR was 8.3 Pa (median, 7.7 Pa) with an IQR of 8.8 Pa. There currently are no required positive pressure levels established for protective environment rooms. While the other types of rooms were relatively stable in pressure over time, the PR showed a large number of fluctuations, with a few sudden, dramatic changes in pressure.

The pressure differential of room PR 4d, for example, located in the middle of a set of four rooms, suddenly

FIGURE 2. Pressure fluctuation in a protective isolation room (PR 4).

dropped from 16.6 Pa to 2.0 Pa between two sample readings, taken 2 days apart. Twelve days later, the pressure dropped further to 0.0 Pa for this room (Figure 2). The following day, after notification of hospital maintenance staff, the pressure in this room was restored to 12.0 Pa after the fan belt was tightened. Sudden pressure increases or decreases such as this occurred in five of the six sampled rooms, with an average pressure change of 10.1 Pa, and ranging from 3.7 Pa to 14.6 Pa. The two PR that did not experience sudden pressure changes, PR 1a-r and PR 3, showed gradual increase or decrease in pressure over the entire sampling time, with overall pressure changes in the magnitude of 10.8 Pa and 3.4 Pa, respectively.

In most rooms, the rate of air change in the PR was somewhat lower than the original design of 15 ACH.⁴ However, the differences between the supply and exhaust rates were found to be 125 cfm or greater, which would help to ensure the room maintained positive pressure.

Room Pressure and Weather Variables

Analysis of weather variables by multiple regression showed little correlation for all rooms between the atmospheric pressure ($P > .05$) and room pressure, relative humidity ($P > .05$) and room pressure, or wind direction and speed ($P > .05$) and room pressure. One influencing factor on room pressure, in terms of weather, appeared to be outdoor temperature, with a slight statistical correlation ($R^2 \leq 0.5$) for 11 of the 18 rooms. The effect was negligible in a practical

sense, with an increase in room pressure of less than 0.01 Pa for each 1 degree Fahrenheit increase in outdoor temperature. Physical explanations for this association are not clear, though they may involve air movement within the building associated with stack effect.

DISCUSSION

This study demonstrated room-pressure fluctuations for the three types of rooms sampled using a method that quantifies the pressure differential. Because most of the studies use a qualitative analysis method vis-a-vis smoke stick, the degree of pressure (airflow direction) has been subjective.

The standard rooms in this study, which were not under any special ventilation control, were expected to have the greatest degree of variation in pressure. The results show, however, that the mean standard room pressurization during the study period was similar to the mean AI pressurization. Likewise, the IQR also was similar for the two rooms, although only about 30% of the readings for standard rooms would have met the CDC's 0.001 in wg requirement for isolation rooms, whereas 68% of the AI rooms met this requirement.⁵ The similarity of the pressurization for the two room types, along with the inconsistency of pressure magnitude, gives evidence of a need for better pressurization control in isolation rooms.

Some authors have suggested the need for greater pressure differentials for isolation rooms than the 0.001 in wg (0.25 Pa) that is recommended by the CDC.⁵ These suggestions have ranged from 0.005 to 0.05 in wg (0.5 Pa to 12.5 Pa).^{6,9} The American Institute of Architects reportedly will recommend in its 2001 guidelines for hospital construction that isolation rooms be constructed to maintain pressures differentials of 0.01 in wg (2.5 Pa). Greater pressure differentials may help to establish and maintain better infection control, but rooms still will need to be monitored closely. This is evidenced by the sharp fluctuations in the PR in this study, which maintained large pressure differentials, but occasionally experienced sharp drops in pressure differential. Therefore, while magnitude of pressure differential is an important factor for the special ventilation room (SVR), other factors need to be considered as well, including air tightness (seal) of the room, careful maintenance, and continuous monitoring of rooms.

The level of pressure due to the offset of ventilation (supply vs exhaust or return) in an SVR may be obviated with a room designed with excessive leakage. In fact, the areas in hospitals are designed to include smoke-barrier status, which means smoke should not be able to penetrate such areas, according to code requirements.¹⁰ Such a basic consideration for making an area airtight already is incorporated into healthcare design; however, little attention is paid to the detail necessary to seal a room completely to prevent leakage of air. The leakage occurs naturally around windows, utility connections (plumbing, electrical, and gas connections), and basic construction detail. To control air leakage and better maintain consistent pressurization of SVR, considerations for an airtight

design should include solid ceilings, caulked connections, and sealed windows.

During construction of the hospital studied, considerations for an airtight design were followed for PR,⁴ but not for AI. When selected rooms of each type (PR and AI) were tested with a pressure test device (blower door) for routine maintenance, pressure was applied to 50 Pa. The airflow into the room at that pressure was monitored, with the AI room allowing for 1,500 cfm leakage while the PR allowed for 150 cfm (personal communication, Andrew Streifel, MPH, 1997). However, the leakage around the ceiling panels in the AI rooms proved excessive. Until such deficiencies are corrected, control remains inconsistent.

It must be recognized that maintenance procedures should be conducted on ventilation systems, including adjusting dampers, tightening fan belts, testing fire-management systems, and thermostat adjustments. However, all of these maintenance operations potentially can alter the ventilation intention of an SVR. For example, we detected large pressure changes in a PR due to change in the position of a room return damper. Such a change was a result of an employee inadvertently moving the damper while cleaning dust from the surface, which resulted in an increase of airflow out of the room. In another instance, a fluctuation in pressure for an AI room was thought to be the result of tightening a fan belt; hence, making the exhaust fan more efficient by moving more air. The rooms with minimal pressure gradients are prone to such changes, which can result in the change of room airflow direction.

Fire-management tests required by the Joint Commission on Accreditation of Healthcare Organizations also may result in altered SVR pressurization if dampers do not reset. The common use of variable air volume in corridors may also change airflow direction in AI rooms that have minimal pressure differentials (<0.25 Pa) due to thermal comfort adjustments brought on by the thermostat demand for change of temperature.

These potential factors for altering airflow indicate a need for close monitoring of pressure variation. Unfortunately, pressure-monitoring devices have additional problems associated with nuisance alarms, often due to low pressure differentials. The PR in this study were equipped with Velocitrol (Honeywell, Minneapolis, MN) pressure monitors that were available during the design and construction phase of the University of Minnesota Hospital and Clinic.⁴ These monitors would sound an audible alarm if the airflow to a PR became too low, although the monitors were not equipped to provide quantitative or logged data. The advantage of such continuous monitoring is that it identifies changes occurring in critical ventilation systems that may alter the intended SVR purpose. For example, in the hospital studied, when a fan belt would start to slip, the alarm for the room at the end of a duct run would sound, indicating a problem with the airflow. This alarm would help to dictate maintenance schedules.

The results of this study indicated changes in the room pressures that at times altered the SVR ventilation

intent, which potentially could result in an infectious event. With the tuberculosis ventilation regulation, the AI are required to be evaluated before admission of a potential tuberculosis patient. There is not a regulation for PR. Continuous monitoring of SVRs is necessary to assure consistent airflow direction in critical patient-care environments. Hospitals should be designed to identify special ventilation needs with specification for ventilation control parameters.¹¹ Without detailed SVR standards, especially for creating an airtight (sealed) room, ventilation control may be inconsistent.

Chile Establishes Law to Control Antibiotic Use

Jaime Labarca

Antibiotics commonly are sold over the counter in Latin American countries. Bavestrello and colleagues from Hospital Dr. Gustavo Fricke, Viña del Mar, Chile, recently studied antimicrobial use and related costs in Chile and reported on how these data were used to implement a governmental policy mandated on prescriptions. Using antibiotic sales in Chile, per year, either in grams of antibiotics or in sale units, they reported a significant increase in the daily defined dose (DDD) per 1,000 person-days. From January 1997 to December 1998, they reported a 498% increase in amoxicillin, 309% increase in oral cephalosporin, and a 473% increase in oral fluoroquinolones. Chloramphenicol was the only antibiotic that decreased (18%) during this period.

A number of groups, including the Chilean Scientific Societies, Ministry of

Health, National Health Institute, and the Health Commission of Congress, met to review these data. It was agreed that a law requiring medical prescriptions for antibiotics was needed. Since it was anticipated that the law would be unpopular, a national educational campaign to rally public support was developed with assistance from the Chilean College of Physicians, the Chilean College Pharmacists, and the National Consumer Services.

One year after the intervention, a second study was done to evaluate the change in consumer behavior and trends in consumption of antibiotics. This second study compared the use of antibiotics in two trimesters, during the same calendar months, the first one before and the second one after the intervention. (October-December 1998 vs the same period in 1999). The consumption and sale of amoxicillin decreased 36%, ampicillin 56%, and

erythromycin 30%. This change resulted in a \$6.4 million (US) savings for the period of 1998 to 1999.

The studies show how scientific data can be used to influence governmental policy to optimize antibiotic use and to help prevent antimicrobial resistance. A collaborative effort among scientific societies and the government contributed to the success of this program. The researchers note that Chile is the first Latin American country to establish mandatory medical prescription for controlling antibiotic use in the outpatient setting.

Room-Based Assessment of Mobile Air Cleaning Devices Using a Bioaerosol Challenge

Alan Beswick^{1,*}, Jodi Brookes¹, Iwona Rosa¹, Claire Bailey¹, Charlotte Beynon², Stephen Stagg^{1,†}, and Neil Bennett¹

Abstract

Introduction: The widespread transmission of the SARS-CoV-2 virus has increased scientific and societal interest in air cleaning technologies, and their potential to mitigate the airborne spread of microorganisms. Here we evaluate room scale use of five mobile air cleaning devices.

Methods: A selection of air cleaners, containing high efficiency filtration, was tested using an airborne bacteriophage challenge. Assessments of bioaerosol removal efficacy were undertaken using a decay measurement approach over 3 h, with air cleaner performance compared with bioaerosol decay rate without an air cleaner in the sealed test room. Evidence of chemical by-product emission was also checked, as were total particle counts.

Results: Bioaerosol reduction, exceeding natural decay, was observed for all air cleaners. Reductions ranged between devices from <2-log per m³ room air for the least effective, to a >5-log reduction for the most efficacious systems. One system generated detectable ozone within the sealed test room, but ozone was undetectable when the system was run in a normally ventilated room. Total particulate air removal trends aligned with measured airborne bacteriophage decline.

Discussion: Air cleaner performance differed, and this could relate to individual air cleaner flow specifications as well as test room conditions, such as air mixing during testing. However, measurable reductions in bioaerosols, beyond natural airborne decay rate, were observed.

Conclusion: Under the described test conditions, air cleaners containing high efficiency filtration significantly reduced bioaerosol levels. The best performing air cleaners could be investigated further with improved assay sensitivity, to enable measurement of lower residual levels of bioaerosols.

Keywords: air cleaner, purification, HEPA, UV-C, bioaerosol, bacteriophage

Introduction

Air cleaning devices are intended to remove particulate material from the air, generally doing so in the background while the treated area is occupied. They differ in design and not all contain scientifically proven technology or provide relevant test data to support manu-

facturer claimed performance.¹ The claims made for the benefits of air cleaners have become so widely publicized, especially in the context of the COVID-19 pandemic, that a rapid evidence review was commissioned by United Kingdom (UK) Government in late 2020, to consider the efficacy of various systems.²

The information from Scientific Advisory Group for Emergencies-Environment and Modelling Group (Sage-EMG) and Chartered Institution of Building Services Engineers^{1,2} emphasizes that air cleaners are most appropriate for spaces where there is insufficient ventilation and/or where existing ventilation cannot be improved. The Sage-EMG also concluded that air cleaning devices using germicidal UV and/or high efficiency air filtration are most likely to achieve safe and effective bioaerosol removal, but that other air cleaning systems, such as those emitting free radicals or ionizing effects, are not excluded from consideration. These other particulate removal methods are, however, deemed less likely to have the impact required to influence airborne disease transmission, based on data available at the time of that review.²

Air cleaners are typically left running for long periods in treated spaces and as such, they should not produce harmful chemical by-products.³ One way to assess their performance is by measuring their clean air delivery rate (CADR). This indicates how rapidly an air cleaner can remove airborne particles from the air of a room and the higher the CADR, the more particles the air cleaner will remove and the larger the room volume it can serve.⁴⁻⁶ Some available systems are scalable, and others can be inserted into existing ventilation ductwork.¹ For the purposes of this study, only floor-standing or wall-mounted units were tested.

Most published air cleaner studies are small-scale assessments of one or two devices, with test conditions often differing greatly between studies, making comparisons of performance difficult. Some published reports are based on first principles, rather than scientific evidence.⁷ Others relate to non-biological air quality tests, rather than bioaerosols.^{8,9} In terms of expressing measured efficacy, some authors have used disease incidence or frequency of disease symptoms in a setting as a measurement method.^{10,11}

Other reports present environmental contamination levels measured before and after air cleaner intervention.^{9,12,13} However, precise data about the ability of a device to reduce bioaerosol levels remain limited and there is little consistency across the design of investigative tests. At the time of writing, no internationally accepted test standard exists for evaluating air cleaning devices performance against bioaerosol challenge, even at the most basic level. Straightforward side-by-side comparisons of multiple systems are also rare.

Safety in use is an important consideration for these devices but despite their widespread marketing, relatively little safety information exists. A published guidance note to health care premises does describe conditions for safe operation.¹⁴ This includes the recommended use of respiratory protective equipment and/or personal protective equipment when filters are changed and the importance of following the manufacturer's instructions

in relation to high efficiency particle arrestance (HEPA) filter/UV lamp replacement and any periodic cleaning of the air cleaner's interior surfaces.

Some reports have suggested ozone as a possible by-product, though this is dependent on the air cleaning mechanism used. Electrostatic particle precipitators are reported as those most likely to cause this by-product due to their use of corona discharge mechanisms.¹⁵ For other types of air cleaner the published information for ozone by-product is limited.¹⁶ Some air treatment devices do produce localized ozone by design, utilizing its biocidal effect, but these systems are generally based on the use of UV and ozone, have no HEPA filtration, and are outside the scope of this study.

The main aim of this study was to test and compare the performance of five air cleaning devices of standalone floor or wall-mounted design, incorporating either HEPA filtration only or HEPA filtration in combination with germicidal UV. The assessments were made using bacteriophage MS2 (hereafter known as MS2), as a bioaerosol challenge, with viable MS2 recovery assessed, alongside parallel total particle count data. MS2 is a single-stranded RNA virus that has been widely used as a mammalian virus surrogate and is known to survive well during aerosolization.¹⁷⁻¹⁹

The five tested devices were all monitored for ozone and hydrogen peroxide (H₂O₂) by-product generation using calibrated measurement sensors capable of parts per million (PPM) level detection or better.

Methods

Air Cleaner Systems Tested

For the purposes of this publication, we refer to the test equipment based on specification and design principles, rather than by brand name. The systems on test are described in Table 1 and all were run on their maximum flow rate during testing, if this feature was adjustable.

Test Room Facility

All testing was carried out in a fully gas sealable exposure chamber of brushed stainless steel construction, with a 34 m³ room volume and temperature and humidity control stabilized at 22°C and 40% relative humidity (RH) respectively, before each test. A stationary air mixing fan, 0.8 m high, was used to ensure the uniform mixing of particles inside the chamber for the duration of each test. On completion of each test, the room was purged with clean air for 30 min, before staff re-entering the room to recover equipment and materials.

Bioaerosol Generation

Bacteriophage MS2 (ATCC 15597-B1) was used as a bioaerosol test challenge for this work. Fresh cultures of MS2 were prepared from frozen bacteriophage stocks and propagated in *Escherichia coli* using nutrient broth

Table 1. Air cleaning equipment tested

Device ID reference	Mode of operation	Additional comments	Claimed air flow rate (if known)
#1	Combined high efficiency filtration and cold atmospheric pressure plasma unit	Small, portable unit. Floor or table top mounted. Brushed steel outer casing. Manual control. Dimensions: $0.19 \times 0.35 \times 0.28$ m. Max. claimed noise level: 55 dB	Claimed max. $150 \text{ m}^3/\text{h}$ with the specification tested. Scalable, depending on application.
#2	Circular HEPA filter unit with radially dispersed clean air delivery.	Wall mounted. Combined powder-coated steel/plastic outer casing. Manual control. Dimensions: $0.2 \times 0.5 \times 0.5$ m. Max. claimed noise level: 72.5 dB	Claimed max. $600 \text{ m}^3/\text{h}$
#3	HEPA EN 1822 H14 level air filtration unit with activated carbon filter.	Wall mounted with heavy duty powder-coated steel outer case. Remote control. Dimensions: $0.59 \times 0.39 \times 0.42$ m. Max. claimed noise level: 58 dB.	Claimed max. $1440 \text{ m}^3/\text{h}$ with cyclonic air circulation, designed to mix room air. Scalable, depending on application.
#4	HEPA EN 1822 H13 with activated carbon filter and UV lamp emitting at 253.7 nm.	Floor-standing unit with lightweight metal case. Remote control. Dimensions: $0.43 \times 0.13 \times 0.72$ m. Max. claimed noise level: 55 dB.	Claimed max. $380 \text{ m}^3/\text{h}$
#5	PM20 grade cotton prefilter, HEPA filter with activated carbon filter. UV lamp emitting at 253.7 nm.	Small portable unit. Floor or tabletop standing. Remote control. Dimensions: $0.30 \times 0.33 \times 0.13$ m. Noise level: not given.	Total air flow rate not provided but claimed CADR: $62 \text{ m}^3/\text{h}$

CADR, clean air delivery rate; HEPA, high efficiency particle arrestance.

(Oxoid) without supplements. Briefly, the preliminary *E. coli* culture (*E. coli* ATCC[®] 15597) was prepared by adding 1 mL *E. coli* stock to 100 mL nutrient broth (1.3% w/v) and maintained at 37°C for 3–4 h in a shaking incubator at 70 rpm. A 100 μL volume of MS2 stock was added to the *E. coli* host culture and maintained overnight at 35°C in a shaking incubator at 70 rpm.

After incubation, the MS2 suspension was centrifuged at 3000 rpm (1690 g) for 10 min to remove host cell debris. The supernatant was filtered consecutively through 0.45 and 0.2 μm filters (Millipore, United Kingdom). To quantify the stock MS2 as plaque forming units per mL (PFU/mL), the freshly filtered stock was diluted using a 10-fold serial dilution in phosphate-buffered saline (PBS). One hundred microliters of each dilution was mixed with 300 μL *E. coli* (3–6 h culture). The MS2:*E. coli* mix was then added to 3 mL nutrient agar overlay and poured onto 1.5% Oxoid nutrient agar plates without supplements and incubated overnight at 35°C. PFU/mL of the MS2 stock was then back calculated. Forty milliliters volumes of MS2 were added to the Collison nebulizer before each test run.

A bioaerosol of MS2 was generated in the exposure chamber using a Collison 6-jet nebulizer,²⁰ operated from breathing quality compressed air delivered at 25 psi for 30 min. This provides a nebulizer flow delivery rate of 12 L/min. The liquid bacteriophage suspension was prepared so as to sit at a starting level exactly 1 cm above the lower tip of the Collison inlet tube, as recom-

mended by the supplier. An assessment of particle sizes generated by the Collison nebulizer, based on Optical Particle Sizer (OPS) measurement, confirmed that the majority of nebulized particles fell within 0.1–1.4 μm size range (data not shown).

This is consistent with the findings of others^{21,22} and is within the respirable particle size fraction, that is, if inhaled, a particle of this size may penetrate deep into the lungs, rather than depositing in the upper airways. It is known that the diameter of droplets generated by sneezing, coughing or speech may vary from <1 to 100 μm , but also recognized that those particles in the medium to large size range may either fall out of the airborne state, or else reduce in diameter due to rapid drying effects while in the airborne state.^{23–25} Based on these earlier reports, the particle sizes produced by the Collison nebulizer were deemed appropriate for this air cleaning challenge study.

Bioaerosol Testing Procedure

Before bioaerosol generation, with the test chamber stabilized at a target temperature of 22°C and 40% RH, the stationary, oscillating air mixing fan was turned on to ensure uniform distribution of aerosols inside the chamber.

Twelve all glass impingers (AGI-30²⁶), each containing the recommended volume of sterile PBS, were placed in the chamber at one collective location. These were used to sample the air sequentially at 12.5 L/min over

four time points across a 3 h test period. The impingers were secured to their stands at worktop height. Vacuum pumps, positioned outside the test chamber, were connected to these via Teflon tubing running through a sealed port in the wall of the test room, allowing pump control from outside the test room. Three impingers were run simultaneously for 15 min at each time point as follows: immediately after aerosol generation ($T=0$); after $T=1$ h; $T=2$ h and $T=3$ h.

Using the earlier cited test conditions and sampling time points, three identical “baseline” control runs were undertaken, to assess the natural decay of the bio-aerosol over 3 h with no air cleaner in the room. A fourth control run was later completed as a final check of sampling equipment performance. This was done before air cleaner testing and the baseline testing was therefore the only test sequence to include four test runs, rather than three. This was then followed by three repeat test runs for each of the five air cleaner devices.

A pre-calibrated optical particle scanner TSI OPS (TSI, Buckinghamshire, UK) was used to log particle measurements over the test period, commencing at background levels just before activating the nebulizer, through to each run completion point. Particle count measurements were made for all control and test sampling runs.

Sample Processing and Quantification

A fresh *E. coli* culture was prepared for each test run by adding 1 mL *E. coli* stock suspension (10^{10} to 10^{11} CFU/mL) to 100 mL nutrient broth and incubating at 37°C for 4 h at 70 rpm in a shaking incubator. Impinger PBS sample volumes were removed by pipetting, and the recovered volume was noted. Sample losses during impinger use were calculated, and fresh sterile PBS was added to replenish the original total volume for each impinger. The air sample suspensions and MS2 stock (as used in the Collison nebulizer) were each prepared as 10-fold serial dilutions. Each dilution of MS2 sample was added in 100 μ L volumes to 300 μ L of the 4 h *E. coli* culture.

The MS2/*E. coli* was then mixed with 3 mL of nutrient semi-solid overlay (maintained at 55°C until used) and immediately poured onto nutrient agar plates. Samples were left to cool and solidify for 20 min and incubated at 35°C for overnight. After incubation, plates were examined visually for PFU, were counted and log reduction was calculated.

Ozone and H₂O₂ by-Product Measurement Close to Air Cleaners

Ozone levels were measured using a 2B Technologies Model 205 Dual Beam Ozone Monitor, accurate to within 1 part per billion (ppb). The pre-calibrated monitor was located outside of the test room, and appropriate diameter Teflon™ tubing was run in to the test area via an access port, with the tip of the tubing placed within

10 cm of the outlet of the air cleaner. Ozone levels were logged constantly, for the duration of each test. H₂O₂ levels were measured with an ATI Portasens III D16 portable gas detector fitted with a newly calibrated low level H₂O₂ sensor, capable of detecting to 0.1 ppm. The whole monitor was placed with its sampler tip within 10 cm of each device during air cleaner operation. The UK workplace exposure limit for both chemicals falls within the low ppm range.²²

Statistical Analysis

The microorganism concentration used for analysis was the mean of the air samples taken at each time point ($T=0$ h, $T=1$ h, $T=2$ h, $T=3$ h) across the multiple test runs. The bacteriophage impinger-based sampling method had a lower limit of detection (LOD) of 200 PFU/m³ of sampled room air. Therefore, an observed value of zero PFU of air might not represent a true zero. To account for this, a $\frac{1}{2}$ LOD value was used in place of a zero reading at sample level, before taking the mean of the three samples at each sampling time point.

Reduction in microorganism levels after 3 h of air cleaning treatment was measured using log reduction analysis over the test period, which was calculated as $\log_{10}$ (untreated air concentration) minus $\log_{10}$ (treated air concentration). As there were three runs for each air cleaning system, there are three log reduction figures and $\log_{10}$ (untreated air concentration) figures for each system. These data are best summarized by showing the range of the values obtained.

The variation in log reduction and log concentration with time was also determined for each system and plotted on graphs to allow a comparison of the systems. These figures were obtained by calculating the mean concentration at each time point across all samples and all runs for each system and then taking the log value. Thus, each point plotted is a log of the mean, rather than a mean of the logs.

The CADR combines the effects of filtration efficiency and the effectiveness of the air cleaner to draw the test chamber's air through it.^{4,5} CADR, therefore, provides an indication of comparable performance between different air cleaning systems. Foarde^{4,5} refers to CADR as CARm when it is applied to microbiological (bio)aerosols, and provides a formula for calculating CARm, which has been applied here in a slightly amended form to derive a metric (rather than imperial) measure:

$$\text{CARm} = 60V(k_e - k_n)$$

where: V is the volume of the test chamber in m³; k_e is the measured particulate decay rate (min⁻¹) for the bioaerosol; k_n is the natural decay rate (min⁻¹) for the bioaerosol; The expression is multiplied by 60 so that CARm is measured in units of m³/h.

The particulate decay rate is defined as the decrease in particles while the air cleaner is operating, whereas the natural decay rate is the decrease when an air cleaner is not used. The work of Foarde^{4,5} provides the formula that is used to calculate decay rate.

The CARM calculations were performed twice; first using the culture-based PFU data, and second using OPS particle counts, which were total counts of all particles within the test room air. In calculating CARM, the concentration of bioaerosols at all available time points was used. As the PFU concentration was measured at $T=0$ h and subsequently every hour for 3 h, the PFU dataset comprises four time points in each run that were used to calculate CARM. This was in contrast to the calculation of log reduction, where only the initial and final time points were used.

The OPS particle counts covering a wide range of particle sizes were logged, reflecting the range of particles present in the test room after bioaerosol generation. The Collison nebulizer produces particles mainly within the 1–10 μm range, and where particles of $<1 \mu\text{m}$ are present, these are counted less reliably by the OPS. For this reason, particles of $<1 \mu\text{m}$ were excluded from the OPS data analysis. The OPS allocates counted particles in to “bins” based on their size, and the closest bin to 1 μm had a minimum threshold of 1.117 μm , so all particles of this size or larger were included. These particles were summed at each time point.

For the purposes of calculating CARM, OPS data were used from the point at which aerosol generation was at its peak (immediately after the aerosol generator was stopped), until completion of the $T=3$ h triplicate air samples. Any values before or after these periods were excluded as they did not relate to the monitored bioaerosol decay period.

For both CARM calculations (using PFU and OPS counts), the decay rate was calculated for each run, and the mean rate obtained for each system, before calculating CARM and its standard error. The formula for the standard error of the CARM was derived here from the standard errors of the decay rates and the formula for CARM above. For example, for air cleaner #4:

Standard error of mean baseline decay rate, SE_B

$$= \sqrt{\frac{\text{Variance of baseline decay rate}}{\text{Number of baseline runs (4)}}}$$

Standard error of mean air cleaner #4 decay rate, SE_N

$$= \sqrt{\frac{\text{Variance of air cleaner #4 decay rate}}{\text{Number of air cleaner #4 runs (3)}}}$$

Standard error of CARM estimate for #4

$$= 60V \sqrt{(SE_B^2 + SE_N^2)},$$

where V is the air volume of the test chamber in m^3 .

Results

Log Reduction

The range of log reduction results obtained after a 3 h test period and $\log_{10}$ (untreated air concentration) for each system across the experimental runs are shown in Table 2.

The untreated concentration of bioaerosol in the room at the start of each test represents the maximum theoretically achievable log reduction, that is, bioaerosol levels present in the room air just as bioaerosol generation was stopped and air cleaning commenced. Bioaerosol reduction exceeding natural decay was observed for all air cleaners. Reductions varied between devices from <2 -log for the least effective, to a >5 -log reduction for the three most efficacious systems (Table 2).

In Table 2, performance differences can be seen for systems 1 and 4. For a well-performing air cleaner, a greater potential for bioaerosol reduction is best demonstrated when the bioaerosol challenge concentrations are higher. Table 2 shows that the starting concentrations for system 1 were lower at the top and bottom of the indicated range compared with systems 2, 3, and 4, despite efforts to maintain bioaerosol challenge consistency across tests.

This may have limited the demonstrable performance of system 1 compared with other air cleaners. Conversely, systems 2 and 5 had very similar bioaerosol starting concentrations, but showed quite different overall log reductions, and here it is clear that system 5 performed less effectively than system 2.

Full bioaerosol removal was never achieved for any of the test systems (Table 2). For some systems, this was where a zero PFU observation was observed after treatment, but where the assay LOD adjustment meant that a PFU figure above zero was substituted instead. This may have underestimated the actual removal efficiency of some air cleaning systems.

Table 2. Range of log reduction values and the range of log(untreated air concentration) values

System identifier	Log reduction range		Log(untreated air concentration) range ^a	
	Minimum	Maximum	Minimum	Maximum
Baseline ^b	0.12	1.55	7.59	9.90
#1	3.14	3.37	5.99	7.30
#2	4.03	5.41	8.14	8.64
#3	3.13	5.39	7.24	8.54
#4	4.71	5.31	7.44	8.86
#5	1.91	2.37	7.89	8.61

Log(untreated air concentration) varies for each system and each run and represents a “ceiling” for maximum log reduction that could be achieved.

^aThis range represents the bioaerosol concentrations immediately after the generation of the bioaerosol atmosphere but before air cleaner was switched on for systems #1 to #5.

^bNatural bioaerosol decay range observed over 3 h and based on four control runs, with no air cleaner in room.

Also in Table 2, the untreated bioaerosol baseline value represents a worst-case scenario in terms of bioaerosol decline as this is where no air cleaner is used and only the natural airborne decay of the MS2 challenge was recorded. Table 2 shows that test system 5 was the least effective of the systems tested, as it gave low levels of log reduction that were substantially below the other systems on test. From Table 2, systems 2, 3, and 4 all gave higher log reductions than system 1, but they also had higher untreated (starting) concentrations.

System 4 performance appeared better than the other systems. However, three data points were recorded for each test system, and at each time point a substantial spread of bioaerosol reduction values was observed despite the consistently applied test approach. This was especially true for system 3, and more data would be needed to unequivocally confirm which system (2, 3 or 4) offered the best levels of log reduction overall, based on PFU counts.

The change in log reduction over time, after the activation of each air cleaner, is shown in Figure 1. The data were derived from the log of the mean of the three test run concentrations obtained at each time point. Each system is represented by a different color and a different line type. As would be expected, the baseline data (no air cleaner) display the lowest rate of log reduction. The worst performing air cleaner system was system 5.

Of systems 1 to 4, three gave substantially higher log reductions (of around 4 logs) during the first hour, whereas the fourth system (system 1) was less effective, with a log reduction of only 1.1 logs after the first hour. However, system 1's log reduction performance continued to increase in a linear manner throughout the test period, reaching 3.3 logs after 3 h. The performance of systems 2 and 3 leveled off after the first hour, so that

their log reductions were 4.4 and 4.0 logs respectively after 3 h. System 4 performance leveled off only after 2 h, achieving a bioaerosol reduction of 5.3 logs after 3 h. Based on Figure 1, system 4 was the best performing air cleaner of those tested.

Table 3 shows the log reduction achieved for each system after 3 h alongside values for the untreated concentration. These data also show the log reduction as a percentage of the "ceiling," another indication of overall system performance, with system 4 again giving the greatest impact by this measure, system 5 the least. Figure 1 presents these data visually, showing the progressive log reduction for each system over time, with Figure 2 providing a further comparison of system performances, showing variation in log concentration over time.

Despite a number of zero PFU counts being recorded over the course of all testing (17 zero counts from a total of 45 mean PFU counts obtained during air cleaners use; data not shown), Table 3 confirms that the adjustment of zero counts using $\frac{1}{2}$ LOD values had only a small effect on calculated log reduction. Data obtained with or without a zero count adjustment demonstrated the same trends and very similar measurement values for each tested air cleaner.

Clean Air Delivery Rate

The calculations of CARM based on PFU concentrations are shown in Table 4 in descending order of efficacy and show that system 5 was the least effective system tested. This was consistent with calculations based on bioaerosol log reduction data, with system 1 the next worst performer. Data in Table 4 show that system 4 had the highest CARM based on PFU concentrations. However, the relatively high standard errors for the three units

Figure 1. Observed log reduction after 3 h and log (untreated air concentration) values by system and run. The log reduction at each time point after the air cleaner is activated is shown. The log reduction here is derived from the log of the mean of the MS2 bacteriophage concentrations across the three runs for each system (four runs for untreated baseline air).

Table 3. Log reduction value after 3 h and showing the “ceiling” log reduction

System	Log reduction after 3 h			Log reduction (as percentage of “ceiling”)	
	Zeroes replaced with $\frac{1}{2}$ LOD value	Include zero counts	“Ceiling” log reduction	Zeroes replaced with $\frac{1}{2}$ LOD value (%)	Include zero counts (%)
Baseline	0.85	0.85	9.38	9	9
1	3.32	3.36	6.99	48	48
2	4.36	4.36	8.48	51	51
3	4.00	4.00	8.15	49	49
4	5.25	5.34	8.46	62	63
5	2.09	2.09	8.45	25	25

The log reduction is derived from the log of the mean of the concentrations across the three runs for each system (four runs for baseline). Two scenarios are included: the first where recorded zero PFU counts are substituted with $\frac{1}{2}$ LOD values; the second where the zero counts are included and not replaced. LOD, limit of detection; PFU, plaque forming units.

with the highest CARM values mean it is not possible to conclude from these data which was the best performing system. System 3 had a particularly high standard error, and this was consistent with the observations in Table 2, as influenced by its performance during test run 1, which was better than its second and third test runs.

An Analysis of Variance test found that there was a highly significant difference in the system decay rates underlying these CARM values (p -value=0.006). A Tukey multiple comparison of means (with a 95% family-wise confidence level) showed that none of the system decay rates were found to be significantly different from each other (adjusted p -value >0.05), with the following exceptions: systems 5 and 2 were significantly different (adjusted p -value=0.021) as were systems 5 and 4 (adjusted p -value=0.006). Importantly, when comparing the decay rates of the best two performers (4 and 2), the adjusted p -value was 0.89.

The calculation of CARM based on OPS counts (Table 5) found that system 1 gave a low CARM value. This was surprising, given the system’s better perfor-

mance based on PFU concentrations, and implies that the OPS data for system 1 may have been skewed. It was noted that the raw OPS particle data for system 1 contained a high number of coincidence error readings (data not shown). This occurs when bioaerosol levels exceed the upper accurate detection range for the OPS and would have influenced OPS particle detection accuracy. Of the remaining systems, system 5 had the next lowest CARM, with a similar value to that obtained using PFU concentrations.

The CARM values calculated for the three remaining systems (system 2, 3, and 4) were all more than double those based on PFU concentrations (Table 4) and the order of performance was reversed, so that system 3 gave the highest CARM and system 4 the lowest CARM of these three systems.

Ozone and H₂O₂ Measurement

Only one system (#1) generated detectable airborne ozone emission during sealed room chamber testing, with a maximum 550 ppbv (0.55 ppmv) detected. This

Table 4. Clean air delivery rate based on plaque forming units concentrations—shown in descending order of performance

System	CADR (m^3/h)	Standard error
4	98.0	10.2
2	86.0	11.1
3	77.3	17.7
1	57.4	6.7
5	34.6	6.9

A decay rate was obtained for each run. The CARm for each system (and its standard error) is derived from these figures.

exceeds the UK workplace exposure limit for ozone gas.²⁷ However, it was recognized that a sealed 34 m³ test environment was not representative of how the unit would be used in the real world. Its residual ozone production was, therefore, tested again in a similarly sized laboratory space with a mechanical ventilation rate confirmed at 8 air changes per hour. Under these conditions, no ozone was detectable. Similarly, there was no detectable evidence of H₂O₂ residue in the air within the test environment for any of the five air cleaners, even with the room sealed for experimental purposes.

Discussion

All systems tested here met the criteria for an air cleaner system that included high efficiency filtration and could treat the air of a room of dimensions used (34 m³). All five test systems demonstrated the ability to remove MS2 bioaerosols successfully from the test room environment, exceeding losses by natural decay alone, though considerable performance variation was observed across the equipment tested. It was always likely that such differences would be observed, since the test systems covered a range of claimed flow rates and system designs.

System 5 consistently gave the weakest performance, in terms of both log reduction (compared with maximum potential) and CADR. This coincided with the lowest claimed flow rate of the five systems so it was not surprising. System 4 gave the best log reduction profile with time. It was one of three systems giving a log reduction of around 4 logs after the first hour of operation. However, unlike systems 2 and 3, there was a further substan-

Table 5. Clean air delivery rate based on total optical particle sizer particle counts (across all bins of size $\geq 1.117 \mu\text{m}$)—shown in descending order of performance

System	CADR (m^3/h)	Standard error
3	435	16.6
2	334	3.8
4	281	11.2
5	29.1	4.1
1	4.0	4.0

A decay rate was obtained for each run. The CARm for each system (and its standard error) is derived from these figures.

tial improvement in log reduction during the second hour of operation for system 4, which was still providing the best log reduction value of all the systems tested during the later stages of the tests.

Even when the maximum achievable log reduction (based on starting concentration) was taken into account by calculating log reduction percentage, system 4 was the best performer. System 4 is a combined HEPA/UV-C treatment system and despite its overall performance, it did not have the highest claimed flow rate of the five systems, based on supplier information.

Four of the five test systems yielded some zero detectable PFU counts during testing. The LOD of the bacteriophage assay meant that this did not necessarily indicate that all MS2 bacteriophage had been removed from the test room air. The effect of adjusting the zero value using a 1/2 LOD value had little effect on log reduction results, with each system's performance trends unchanged.

Although three systems provided higher log reduction performances than system 1 over the 3 h test period, system 1 performance did not level off in the manner of systems 2, 3, and 4. Bioaerosol log reduction using system 1 increased at a constant rate, and thus we might speculate that if the test period had been longer, system 1's performance might have exceeded that of the other systems. Only a longer test period could confirm this, and this was beyond the scope of the current study.

When CADR was calculated using PFU concentrations, there was a highly significant difference in the system decay rates underlying these CARm values. System 4 gave the best performance, but there was not a statistically significant difference between this and the next best performer, system 2 or any of the other systems, apart from system 5.

The calculation of CARm based on OPS counts found that system 1 gave an unexpectedly poor CARm value. This is surprising given the system's performance based on PFU concentrations, and it implied that OPS data for system 1 were in some way inaccurate. This may have occurred because the OPS data for system 1 were found to have numerous "coincidence errors," which reflect the OPS trying to measure aerosol levels beyond its calibrated range.

If particle concentration is increased sufficiently, more than one particle occupies the same space in the OPS sensing volume and "coincidence" occurs, resulting in a drop in counting efficiency and particle sizing inaccuracy.²⁸ This can cause inconsistencies in OPS performance and may explain why the OPS CARm value was not as high as expected for system 1. Of the remaining systems, system 5 gave the next lowest CARm, with a similar value to that obtained using PFU concentrations.

However, the CARm values calculated for the three remaining systems (2, 3, and 4) were all more than double

those based on their PFU CARm performance. Based on OPS particle counts, the order of performance was therefore reversed, so that system 3 gave the highest CARm and system 4 the lowest value of these three systems.

The OPS counts and associated CARm values clearly indicate that system 3 was the best performing machine, despite the high standard error of its estimated CADR. The authors are aware of a specific recommendation for system 3 operation that may have influenced its performance. In operating this device, the manufacturer recommends it be allowed to run and acclimatize for ~30 min before testing as opposed to turning the device on immediately after bioaerosol chamber release.

To keep test conditions consistent with other systems and to allow bioaerosol delivery into the chamber immediately before air cleaner activation, this device acclimatization was not possible. This may explain some inconsistencies in the performance of system 3.

The PFU log reduction figures conclusively show system 4 as the best performing system. However, the relative performance of the different systems based on CARm varies substantially according to the type of count data used, so it is not possible to conclude which is the best system tested overall, based on PFU and OPS counts. What is clear is that systems 2, 3, and 4 are consistently the strongest performers and these devices are based on HEPA, HEPA, and HEPA/UV-C respectively.

Airflow is clearly important to the performance of air cleaners, but the results from air cleaner 4, which did not have the highest claimed airflow value (Table 1), demonstrate that airflow rate alone is not the whole story. Other factors may come in to play, such as the internal design of the air cleaner systems, including the size and quality of the installed HEPA filter(s) and related filter fit/sealing within the machine.

Also, the presence/absence of additional elements such as coarse filters/germicidal UV lamps/physical baffling to slow air flow down over UV emitters. During this study, we used the air cleaners as received and did not open them up to see how well they were put together internally, so such influences were outside the scope of our investigation.

Conclusion

To date, there is little information and a lack of consistent research regarding the ability of air cleaning technologies to remove bioaerosols in a side-by-side comparison study. This work reports a comparison study using a selection of air cleaning devices, which were either portable/floor standing or wall mounted, to determine their efficiency against a biological challenge in combination with CARm assessment. Under the described conditions, all the selected air cleaners provided some reduction in the bioaerosol concentration.

These devices were evaluated using high bioaerosol challenge concentrations, probably far higher than most real-world situations would create. Some devices performed well under these challenging conditions, reducing the concentration below the experimental detection threshold. To determine more definitive CARm, the best performing air cleaners could be investigated further with improved assay sensitivity, to enable measurement of lower residual levels of bioaerosols.

Overall, when considering the high level of biological challenge, the worst performing device still demonstrated a measurable reduction in bioaerosol concentration. This suggests that in real-world scenarios, even the worst performing device could potentially help to mitigate bioaerosol spread and may offer benefits for reducing the airborne spread of viruses such as SARS-CoV-2.

Clean air delivery rate

SUMMARY

Background: The global COVID-19 pandemic has resulted in a greater interest in improving the ventilation of indoor environments in order to remove aerosolized virus and thus reduce transmission. Air purification systems have been proposed as a solution to improve aerosol removal.

Aim: The aim was to determine the efficacy of air purification systems in reducing the viral load in the environmental air of a room.

Methods: A containment room equipped with HEPA filter on air intake and exhaust was constructed. It was connected via an inlet with the BSL-2 facility. From the BSL-2, Feline Coronavirus (FCoV)-loaded aerosols were released into the containment room. After nebulization, air sampling was performed to determine the viral load in air prior to assessing the clean air delivery rate of the air purification systems. The infectivity of the captured viruses was also examined.

Findings: The air purification systems realized a 97–99% reduction in viral load in air in 1 h.

Captured infectious FCoV was reduced by 99.9%–99.99% by use of an ESP technology.

Conclusions: The air purification systems, using ESP technology or HEPA filter, reduce the viral load in air. The ESP purifiers inactivate captured FCoV viruses. Therefore, air purification systems can be used as an adjunctive infection control measure.

Introduction

The global COVID-19 pandemic caused a dramatic change in our socio-economic life. Social distancing, self-isolation and travel restrictions caused a reduced workforce across all economic sectors resulting in a loss of jobs [1]. Lockdown and

school closures have placed a substantial mental health burden on children and college students [2].

According to current knowledge about transmission, SARS-CoV-2 transmission primarily occurs between people when an infected person is in close contact with another person. The extent to which the virus will transmit between individuals

depends on the amount of infectious virus being shed and expelled by a person, the type of contact that person has with other individuals, the setting where exposure occurs, and what preventative measures are in place [3]. In laboratory studies, after an initial 90% loss of viability [4], SARS-CoV-2 remained infectious in aerosols for at least 3 h with a reduction in infectious titre from $10^{3.5}$ to $10^{2.7}$ TCID₅₀ per litre of air [5]. In normal circumstances, particles will also be lost by gravitational deposition. Micro-organisms including viruses migrate as droplet nuclei in indoor air. These can be removed by processes such as ventilation, filtration, electrostatic precipitation, and combinations thereof [6,7].

Electrostatic filtration by electrostatic precipitator (ESP) uses an electrostatic charge to generate air ions. This technology is commonly used in industry to charge particulate matter such as dust, smoke and fungal spores and filter them by deposition on oppositely charged plates [8]. Particles with sizes $<0.03 \mu\text{m}$ are not charged and the efficiency of the filter decreases for particle sizes $<0.05 \mu\text{m}$ [9,10]. HEPA filters consist of fibrous media made with multiple layers of randomly arranged fibres that trap airborne particles via three mechanisms, inertial impaction, interception and diffusion. Their combined action dictates the efficiency of the filter. Although there are no recommendations by the CDC for application of HEPA purifiers for air decontamination of airborne SARS-CoV-2, HEPA purifiers should be considered an adjunctive infection control measure [11].

This study aimed to establish and apply a method for determining the efficacy of air purification systems in reducing virus-loaded aerosols in a room. Four air purification systems were included in the study representing ESP and HEPA filtration. These were tested for their efficacy in removing viral aerosol, bacteriophage MS2 [12] and Feline Coronavirus (FCoV) [13] from air. FCoV was used as a surrogate for SARS-CoV-2 because it represents an enveloped virus highly similar to SARS-CoV-2. It has a similar envelope structure with spike-protein, virus size of about 120 nm and ssRNA type of genome [13], but has fewer biosafety implications despite the impact on feline health [14].

Material and methods

Biological material

The biological agents used in the project are described in Table I.

Table I
Biological materials used in the study

Biological species	Description	Source/number	Characteristics
<i>Escherichia coli</i>	<i>E. coli</i>	DSM 5695	Host for MS2 bacteriophage
MS2 bacteriophage	MS2	DSM 13767	RNA-virus (single strand RNA) in protein coat, diameter about 25 nm (1)
Crandell-Rees Feline Kidney cells	CRFK cells	Faculty Veterinary Medicine Utrecht	Host for FCoV
Feline Coronavirus	FCoV	Faculty Veterinary Medicine Utrecht	RNA-virus (single strand RNA approximately 30 kb) enveloped with lipid layer with S-protein, diameter about 120 nm (2)

Containment room for air purification experiments

A containment room was constructed for performing the air purification experiments. The room had a volume of approximately 50 m^3 (width $4.5 \text{ m} \times$ depth $4.3 \text{ m} \times$ height 2.6 m) and was physically closed from the external environment by a door with rubber seals and door-lock for controlled entrance. For sampling, the containment room was connected to a BSL-2 laboratory via a double door lock equipped with a UVC and chemical disinfection system that enabled the workers to manage the processes in the containment room and to collect samples in a controlled way without risk of spreading viral particles outside the containment room. The intake and exhaust air of the containment room were both HEPA filtered. The room was cleared of biological material after every experiment by UVC disinfection (Signify, Eindhoven, The Netherlands) and by air refreshment of 300 m^3 air per hour via HEPA filtering. Shaded places are treated by chemical disinfection. Air sampling was performed by using a Coriolis air sampler (Bertin Technologies, Montigny-le-Bretonneux, France).

Air purification systems

The air purification systems used in the study were supplied by the partners of the PPP Room disinfection project. The air purification systems applied ESP or HEPA technology with an airflow of $400\text{--}500 \text{ m}^3/\text{h}$.

Virus nebulization and sampling

The viruses, MS2 bacteriophages and FCoV viruses, were aerosolized using an eFlow® rapid nebulizer (PARI GmbH, Germany). This nebulizer applies a vibrating plate and appears to be more gentle on viral particles compared with jet nebulizers and is used for nebulization of high counts of bacteriophages against tuberculosis [15]. The system released 0.28 mL virus suspension per minute. The aerosol particle size released by the eFlow is up to $5 \mu\text{m}$ [16]. These particles were transported and released into the containment room via a tube with an airflow of 1 bar pre-pressure. To prevent accidental release of virus from the nebulizer system to the environmental air, it was placed in a closed plastic box in the BSL-2 laboratory from which the nebulized virus containing mist was transported via a tube of 50 cm directly into the containment room.

Air sampling was performed by the Coriolis sampler (Bertin Instruments, France) that samples 300 L of air per minute. This

sampler demonstrated good biological sampling efficiencies and physical sampling efficiencies for viruses in a comparative test [17]. The samples were collected in a small beaker containing 15 mL of sampling liquid, which was placed in a UVC-closed transport box after sampling to prevent UVC illumination. Sampling liquid was sterile saline solution for MS2 bacteriophage and DMEM cell culture medium including 0.45% glucose, 2 mM L-glutamine and 100 U/mL penicillin and 100 U/mL streptomycin without 2% fetal calf serum for FCoV. Air samples taken by the Coriolis sampler in the containment room were transported into the BSL-2 laboratory via the inlet equipped with a double door. Application of UVC and chemical disinfection with VirkonS (Biosecurity BV, The Netherlands) prevents environmental release of virus upon transportation of the contained material in the transport box via the inlet into the BSL-2 laboratory. The samples were processed in the biosafety cabinet of the BSL-2 laboratory.

Sample analysis

Samples were analysed using two different approaches. Firstly, by detection of biological activity, implying infection of target cells and subsequent lysis of the cells. For MS2 bacteriophage samples, these samples were serially diluted and spread on Luria-Bertani Agar (LBA) (Oxoid Limited, USA) plates in overlay with confluent seeded *Escherichia coli* in LBA 0.5% w/v top agar. The plates were incubated at 37 °C for 24 h, after which the plaques of lysed *E. coli* cells were counted. For FCoV-containing samples, an infectivity assay was performed [18] whereby serial dilutions were seeded on cell cultures of CRFK cells on DMEM including 0.45% glucose, 2 mM L-glutamine and 100 U/mL penicillin and 100 U/mL streptomycin supplemented with 2% fetal calf serum in 96-well microtitre plates. After two days of incubation at 37 °C in a CO₂ incubator, the wells of the plate were inspected for the cytopathic effect of the virus on the monolayer of CRFK cells and scored for TCID₅₀.

Secondly, samples were analysed by detection and quantification of the viral genomes using reverse transcriptase quantitative PCR (RT-qPCR). Prior to PCR, RNA was extracted and purified from the FCoV samples by using the QIAamp Viral RNA Mini Kit (Qiagen, Netherlands) according to the supplier's protocol. A one-step RT-qPCR was performed on a mixture of 5 µL purified viral RNA, 0.4 µM Fel-CoV-F forward primer, 5'-TGCCACAGGATGGGCTTAC-3', 0.5 µM Fel-CoV-R reverse primer, 5'-TTGTCACTACGTGCTTCT GTTGAG-3', 0.25 µM Fel-CoV-P-FAM/MGB probe, FAM-5'-ACGTAAAATCTAAAGCTGGTG-3'-MGB, and TaqMan Fast virus 1-step Master mix (Applied Biosystems, USA) in a total reaction volume of 25 µL. The thermocycler programme was 5 min at 50 °C, 20 s at 95 °C, 40 cycles alternating 15 s at 95 °C and 60 s at 60 °C. The RT-qPCR assay yields information on the quantity of the amount of target FCoV RNA based on a standard curve. It reflects the number of viruses both infectious and non-infectious that were sampled and thereby the basis to calculate the number of FCoV genome equivalents; the size of the FCoV RNA genome is about 30 kb [13], which equals 0.016 fg.

Decay of MS2 loaded aerosol in the containment room

MS2 phage suspension of about 1×10^{10} pfu/mL was prepared by culturing the phage on *E. coli* on LBA plate, scraping the top agar layer from the plate and resuspending in 5 mL

phage buffer according to DSMZ protocol (DSMZ, Germany). After subsequent centrifugation at 4000 g and filtration of the supernatant through a 0.45-µm filter, the filtrate was nebulized at 0.28 mL/min for 5 min into the containment room of 50 m³ using the e-Flow vibrating mesh nebulizer (Pari GmbH, Germany) while the air mixing was constantly achieved by four fan units. One minute after nebulization, the $t = 0$ sample was collected by the Coriolis sampler at 300 L/min for 3 min, which resulted in 900 L of sampled air. Subsequent samples were taken at $t = 15$ min, $t = 30$ min, $t = 45$ min and $t = 60$ min. These phage recovery data indicate the natural decay of MS2 phage in the containment room. Following the same nebulization and sampling conditions, the air purification systems' effect was explored on additional removal of MS2 phage loaded aerosol in the containment room. The decay realized by the air purification system was calculated by total decay with purifier action minus natural room decay without purifier action based on triplicate tests.

Decay of FCoV loaded aerosol in the containment room

The FCoV suspension was prepared by virus culturing on CRFK cells on DMEM including 0.45% glucose, 2 mM L-glutamine and 100 U/mL penicillin and 100 U/mL streptomycin supplemented with 2% foetal calf serum. After centrifugation at 4000 g, the FCoV suspension was nebulized. The decay of FCoV loaded aerosol was measured upon the action of the air purification systems. In the experiments with FCoV, a TCID₅₀ load of FCoV in the suspension was about 2.5×10^5 /mL. Because infectious virus could hardly be retrieved from the containment room at $t = 0$, the virus was detected using the FCoV specific RT-qPCR. All tests were performed in triplicate.

Calculation of clean air delivery rate, single pass efficiency and log and percentage reduction

The effectiveness of an air purification system in reducing the viral load in air was assessed while the aerosol load was constantly homogenized in the room. Based on the ANSI/AHAM AC-1-2006 test method [19], air cleaning for smoke, fine dust and pollen can be expressed as Clean Air Delivery Rate (CADR). In line with this, the CADR was calculated for virus-loaded aerosols. The following two formulae were used:

$C_{tx} = C_{t0} e^{-\kappa tx}$, where C is concentration at time point tx or $t0$ and κ is decay constant.

$CADR (m^3/h) = V(\kappa_t - \kappa_n)$, where V is volume test chamber, κ_t is test decay constant and κ_n is natural decay constant.

Percentage reduction was calculated based on log reduction by the formula:

$P = (1 - 10^{-L}) \times 100$, where P is percentage reduction and L is log₁₀ reduction.

Determination of virus inactivation upon capturing in purifier system

The air purification system using ESP technology contains a collector tube for capturing the particles. The captured virus particles were analysed for remaining infectivity. This was performed by examining the ratio of the TCID₅₀ per quantity of virus RNA determined by RT-qPCR on the FCoV virus particles collected on the collector inside the purifier system. For this,

nebulized FCoV was directly released from 50 cm distance into the inlet of the active air purification system for 5 min. After virus nebulization, the fan units in the containment room were switched on and the virus containing air in the room was exchanged with fresh air by 1 h ventilation of 300 m³ of air through the HEPA filter in the exhaust of the room and additional UVC treatment for virus inactivation of environmental virus in the containment room. Then, three areas of 10 × 10 cm of the internal collector tube in the air purification system were sampled individually by wet swab to collect virus material. The swabs were each directly submerged into 3 mL of DMEM medium with 50% v/v glass beads to resuspend the viruses into the medium by vortexing for 1 min. These virus suspensions were examined for TCID₅₀ and viral RNA content by RT-qPCR after RNA isolation. For reference, the natural stability of the virus on the collector surface was explored by nebulizing the virus on top of stainless-steel surfaces. The plates were dried in the biosafety cabinet for 15 min and then swab samples were taken after 1 h. The recovered viruses from the surface were analysed for TCID₅₀ and total viral RNA by RT-qPCR. The difference between TCID₅₀/fg of viral RNA ratio of the control and the collector surface of the purifier system allowed calculation of the reduction of viral infectivity.

Results

Decay of MS2 loaded aerosol in the containment room

MS2 phage decay in the containment room was measured with and without an active air purification system. Natural decay of phage presence and decay by the action of the air purification systems are shown in Table II. The natural phage MS2 decay in the room without an active air purification system appeared to be about 0.3 log units in 1 h. In the presence of each of the four types of air purification systems, A, B, C and D, we observed greater phage MS2 decay compared with the natural decay, ranging from about 1.7 to 2.3 log units or 98%–99.5% reduction in a period of 1 h.

Decay of FCoV loaded aerosol in the containment room

FCoV loaded aerosol decay in the containment room was measured with and without an active air purification system. In the absence of an active air purification system, infectious viruses were hardly detected. Only 0.8 log TCID₅₀ per mL sample was obtained at $t = 0$. A decline of infectious properties of the airborne viruses at low relative humidity was previously also observed by Oswin *et al.* [4]. Based on quantity

determination of FCoV virus in sampled air using the FCoV specific RT-qPCR, the number of genome equivalents of the virus could be detected in the room. At $t = 0$, the number of FCoV genome equivalents is about 9.1 log/m³ and in the absence of an active air purification system, the number reduced to about 8.7 log/m³ of air in 1 h (Figure 1). In the presence of an active air purification system, the FCoV reduction in air proceeded faster compared with the natural reduction of FCoV particles in the containment room (Figure 1, Table III). The natural reduction in the containment room is about 0.4 log units per hour. The decay attributable to the air purification systems ranges from about 1.5 to 2.3 log units or 96.8%–99.5% reduction in 1 h (Table III).

Calculation of clean air delivery rate and virus inactivation

The CADR of the different air purification systems was calculated for both MS2 bacteriophage clearance (based on plaque forming units) and for FCoV particle clearance (based on qPCR quantified viral RNA). The CADR values obtained with the air purification systems for both types of particles, e.g., aerosol containing MS2 and aerosol containing FCoV, were in a range of about 169–290 m³/h (Table IV).

Apart from the CADR, it was also relevant to conclude on the fate of the captured FCoV particles. Because the aerosolized FCoV loses its infectivity at low relative humidity, the FCoV-loaded aerosol was directly inhaled by the active air purifier systems. The subsequently sampled viral material from the inner metal collector surfaces of the ESP systems showed at least a factor 1000 to 10,000 less TCID₅₀ per fg viral RNA compared with FCoV containing aerosol sedimented on steel plates. This experiment indicated a reduction of viral infectivity of at least 3 log or 99.9% of captured viral particles by the ESP-based air purification systems (Table IV). Attempts to retrieve viral material from HEPA by grinding and vigorous shaking in DMEM appeared unsuccessful.

Discussion

The configuration of the containment room with four ventilators in the corners realizes a constant homogeneous distribution of virus loaded aerosol in the room. This was visually confirmed by releasing smoke from the point of virus release at one side of the room. By the action of the air purification systems, a constant intake of aerosol is realized and a concomitant output of purified air. The collected data shows therefore a decay of the viral load in the air as captured by the sampler over time. By correcting the natural decay of viral load in the room, the contribution of the air purification system to the decay could be determined as shown in Tables II and III, which show the reduction of virus in 1 h. Irrespective of the type of virus, MS2 phage or FCoV, the purifiers realize a decay of about 96.8–99.5% in 1 h. Beswick *et al.* [20] showed similar MS2 decay data for air cleaning systems in a comparable room setting.

The decay of bacteriophage MS2 could be analysed by quantifying the number of infectious particles in the samples of air. The numbers of this virus in the air were in the range of about 10⁸ plaque forming units per cubic metre; thus, there was enough virus to show plaque formation when seeding the particles collected from 900 L of air in 15 mL of sampling liquid

Table II

MS2 decay averaged data and data corrected for natural decay in the room in the absence of a purifier system for 60 min

System	MS2 decay in log units	Corrected MS2 decay in log units	Corrected MS2 decay percentage
Natural	0.3 ± 0.5	0	0.0
System A	2.5 ± 0.4	2.2	99.4
System B	2.6 ± 0.3	2.3	99.5
System C	2.0 ± 0.3	1.7	98.0
System D	2.6 ± 0.2	2.3	99.5

Decay data is provided as Log and percentage reduction in 60 min.

Figure 1. Feline Coronavirus (FCoV) genome equivalent decay in containment room per cubic metre. Natural decay is indicated in the upper blue line with diamonds and the decay with additional action of four air purification systems A, B, C and D are given in green line, dark blue line, light blue line and dark green line, respectively.

with the Coriolis sampler. This results in about 10^8 infectious viruses in 15 mL if all viruses are collected. Despite some sampling efficiency loss, MS2 virus always showed a plaque count on plates with *E. coli* target bacterium. Unfortunately, infectious particles of FCoV could only be found in the samples at low TCID₅₀ counts; the reason for this was that the number of FCoV that can be captured in 15 mL sampling liquid is about TCID₅₀ of 100. This is close to the limit of detection with additional inactivation of FCoV because of low relative humidity of the air. Oswin *et al.* [4] showed that the low humidity does severely affect infectivity to about 10% of the starting value for SARS-CoV-2 over 20 min. Because FCoV has an identical structure and size [13], the fate of the virus is anticipated to be similar. An alternative method to detect and quantify the virus particles was by targeting the RNA genome of the virus by RT-qPCR. This seemed successful and yielded

Table III

Feline Coronavirus (FCoV) genome equivalent decay based on RT-qPCR averaged data and data corrected for natural decay in the room in absence of a purifier system for 60 min expressed as log and percentage reduction in 60 min

System	FCoV genome decay in log units	Corrected FCoV genome decay in log units	Corrected FCoV decay percentage
Natural	0.4 ± 0.1	0	0.0
System A	2.2 ± 0.1	1.8	98.4
System B	2.7 ± 0.1	2.3	99.5
System C	1.9 ± 0.2	1.5	96.8
System D	2.6 ± 0.1	2.2	99.4

insight into the numbers of viral genomes sampled regardless of the virus' infectiousness. The decay of FCoV in the containment room as a result of the action of the air purification systems show a similar trend of about 2 log reduction in 1 h as roughly also observed for the decay of MS2. This trend is likely the result of the similar type of aerosols released by the MESH nebulizer that releases similar volumes of aerosols, which may be influenced by the different nature of the virus and the medium. Importantly, it provides confidence in the applied methodology and demonstrates a similar result of particle capturing of the purifier systems. However, typical differences in virus capturing were observed when having a more detailed look at the log reduction data and calculated CADR. The trend based on the CADR data in Table IV suggests a slightly better CADR for MS2 compared with FCoV-loaded particles. This may suggest a slightly different type of aerosol for the two different viruses. None the less, the ESP- and HEPA-based purifiers show a CADR range that has been previously described for medium-sized particles in the range of 0.5–3.0 μm [21] and for ultra-fine particles by HEPA-based purifiers [22]. The CADR was shown to depend on the nature of airborne particles [21]. Despite the minor differences in CADR observed when challenging the systems with two distinct types of virus-loaded aerosol, these differences show a similar trend depending on the air purification system. This is in line with the statement that the CADR permits an intercomparison of performance among various air cleaners [21].

The publication by Feng *et al.* [23] expressed the fear of re-aerosolization of infectious SARS-CoV-2 from HEPA and ESP air purification systems. They proposed in their simulated filtration performance study that UVC treatment should be added as technology to air purification systems to eradicate virus

Table IV

Clean Air Delivery Rate (CADR) of purifier systems based on exposure of nebulized MS2 bacteriophage and nebulized Feline Coronavirus (FCoV) particles in separate experiments in a 50-m³ containment room

System	CADR (m ³ /h) MS2 aerosol	CADR (m ³ /h) FCoV aerosol	Log reduction of infectivity captured FCoV	Percentage reduction of infectivity captured FCoV
System A	268	200	4.1	99.99
System B	290	263	3.1	99.92
System C	229	167	3.7	99.98
System D	281	243	ND ^a	ND ^a

CADR is calculated based on experimental data shown in previous paragraphs. Infectivity reduction of captured FCoV virus is shown in the latter two columns.

^a Virus could not be retrieved from HEPA matrix; no TCID₅₀ nor qPCR amplifiable RNA was detected.

infectivity. Moreover, they stated that the biological disinfection effect on SARS-CoV-2 aerosols exposure to ions and electric field should be investigated. The latter has been carried out in this study using the surrogate virus FCoV that has identical structural and physical characteristics to SARS-CoV-2 but only has a different host range. The outcome of our study demonstrates that ESP inactivates the captured FCoV by 3–4 log units that equals a reduction of infectiousness of about 99.9% to 99.99%. Similar inactivating effects on captured bacteriophages by an ESP-based system has been reported by Kettleson *et al.* [24].

Our findings indicate that the HEPA- and ESP-based air purification systems evaluated in this study reduced the viral load in air. The captured viruses were inactivated by a percentage of 99.9–99.99% in the ESP systems that apply a strong electric field for capturing airborne particles. From this study it can be concluded that the evaluated air purification systems can be used as adjunctive infection control measure.

Conflict of interest statement

The authors declare the research was conducted to find out whether air purification systems could be used as additional infection control measure. Although the project was also financially supported by the partners Genano, Euromate, Formula Air and VFA Solutions, their support did not pose any conflict of interest as TNO executed the work as an independent research organization. The protocol and work were designed and carried out without any input from the manufacturers.

Funding sources

This work was financially supported by Health Holland, Genano, Euromate, Formula Air and VFA Solutions.

Airborne severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) was detected in a coronavirus disease 19 (COVID-19) ward before activation of HEPA-air filtration but not during filter operation; SARS-CoV-2 was again detected following filter deactivation. Airborne SARS-CoV-2 was infrequently detected in a COVID-19 intensive care unit. Bioaerosol was also effectively filtered.

Keywords. SARS-CoV-2; air filtration; COVID-19; nosocomial infection; airborne pathogens.

Airborne dissemination is likely an important transmission route for severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) [1], with SARS-CoV-2 RNA detected in air samples from coronavirus disease 2019 (COVID-19) wards [1, 2].

Despite the use of personal protective equipment (PPE), there are multiple reports of patient-to-healthcare worker transmission of SARS-CoV-2 [3], potentially through the inhalation of viral particles [4]. There is a need to improve the safety for healthcare workers and patients by decreasing airborne transmission of SARS-CoV-2 [4]. Portable air filtration systems, which combine high efficiency particulate filtration and ultraviolet (UV) light sterilization, may be a scalable solution for removing respirable SARS-CoV-2 [5]. A recent review by the UK Scientific Advisory Group for Emergencies modeling group found limited data regarding the effectiveness of such devices [6]. Here we present the first data providing evidence for the removal of SARS-CoV-2 and microbial bioaerosols from the air using portable air filters with UV sterilization on a COVID-19 ward.

METHODS

The study was conducted in 2 repurposed COVID-19 units in Addenbrooke's Hospital, Cambridge, United Kingdom. One area was a "surge ward" (ward) managing patients requiring simple oxygen therapy or no respiratory support, the second was a "surge intensive care unit" (ICU) managing patients requiring invasive and noninvasive (noninvasive ventilation, high flow nasal oxygen) respiratory support. The ward was a fully occupied 4-bedded bay (Figure 1A top left panel). The ICU was fully occupied 5-bedded bay, with a supra-capacity sixth occupied bed used in week 2 (Figure 1B top left panel). Both units were passively ventilated, with 2–4 air-changes per hour at baseline.

In the ward we installed an AC1500 HEPA14/UV sterilizer (Filtrex, Harlow, UK); in the ICU we installed a Medi 10 HEPA13/UV sterilizer (Max Vac, Zurich, Switzerland). The air filters were placed in fixed positions before the initiation of the three-week study period (Figure 1A and 1B), switched on at the beginning of week 2 and run continuously from Sunday to Sunday for 24 hours per day, providing approximately 5–10 room-volume filtrations per hour.

We performed a crossover evaluation, with the primary outcome being detection of SARS-CoV-2 RNA in the various size fractions of air samples. Air sampling was conducted using National Institute for Occupational Safety and Health (NIOSH) BC 251 2-stage cyclone aerosol samplers [7] (B Lindsley, Centers for Disease Control and Prevention [CDC]), operated in accordance with previous studies [7, 8]. Air samplers were assembled daily with a control sampler left in a sealed bag. Samplers were placed adjacent to the air filter inlet and the other at approximately 4 meters from the filter and no closer than 2 meters to patients. In ICU 2 distant samplers were used: 1 mounted at head height and 1 at bed height. Samplers were operated on

weekdays (from 08:15 to 14:15) for 3 consecutive weeks. After sampling, samplers were disassembled using sterile technique. The samples were processed and then stored at -80°C until analysis

Nucleic acids were extracted from each NIOSH sampler component (tubes containing large aerosols, medium aerosols, and filter). Methodological details including extractions, reverse transcription quantitative polymerase chain reaction (RT-qPCR) for SARS-CoV-2 and high throughput qPCR assays for a range of bacterial, viral, and fungal pathogens are in the [Supplementary Methods](#) (organisms listed in [Supplementary Table 1](#)). Differences in numbers of pathogens detected with filters on and off were compared by Mann-Whitney *U* test, and $P \leq .05$ was considered significant.

RESULTS

From 18 January to 5 February beds in the ward and ICU were at 100% occupancy; 15 patients were admitted to the ward, and 14 were admitted to the ICU over the sampling period. All patients were symptomatic and tested positive for SARS-CoV-2 RNA.

In the ward, during the first week while the air filter was inactive, we were able to detect SARS-CoV-2 on all sampling days; RNA was detected in both the medium (1–4 μM) and the large ($>4 \mu\text{M}$) particulate fractions ([Figure 1A](#) lower panel). SARS-CoV-2 RNA was not detected in the small ($<1 \mu\text{M}$) particulate filter. The air filter was run continuously in week 2; we were unable to detect SARS-CoV-2 RNA in any of the sampling fractions on any of the 5 testing days. We completed the study by repeating the sampling with an inactive air filter. As in week 1, we were able to detect SARS-CoV-2 RNA in the medium and the large particulate fractions on 3/5 days of sampling (a sample without tube size indicated tested positive on day 5) ([Figure 1A](#) lower panel). SARS-CoV-2 RNA was not detected from the control sampler.

We subjected the extracted nucleic acid preparations to high-throughput qPCR to detect a range of viral, bacterial, and fungal targets. In week 1, we detected nucleic acid from multiple viral, bacterial, and fungal pathogens on all sampling days ([Figure 1A](#) top, middle, and right panels). In contrast, when the air filter was switched on, we detected yeast targets only on a single day, with a significant reduction ($P = .05$) in microbial bioaerosols when the air filter was operational ([Figure 1A](#)). Using this high-throughput approach, SARS-CoV-2 RNA was detected on 4/5 days tested in week 1 but was again absent in week 2. We were unable to generate multiplex

data for week 3 due to sample degradation following SARS-CoV-2 RNA amplification.

In contrast to the ward, we found limited evidence of airborne SARS-CoV-2 in ICU in weeks 1 and 3 (filter off) but detected SARS-CoV-2 RNA in a single sample in the medium (1–4 μM) particulates on week 2 (filter on) ([Figure 1B](#) lower panel). This contrary result did not reflect a general lack of bioaerosols in the ICU, which demonstrated a comparable quantity and array of pathogen associated nucleic acids to that seen in the unfiltered ward air on week 1 ([Figure 1B](#) top, middle, and right panels). Again, the use of the air filtration device significantly ($P = .05$) reduced the microbial bioaerosols ([Figure 1B](#)); with only 3 organism types detected on 2 of the sampling days. SARS-CoV-2 RNA was only detected once during week 1 on the high throughput qPCR assay.

DISCUSSION

Our study represents the first report to our knowledge of removal of airborne SARS-CoV-2 in a hospital environment using combined air filtration and UV sterilization technology. Specifically, we provide evidence for the circulation of SARS-CoV-2 in a ward within airborne droplets of $>1 \mu\text{M}$. Droplets of 1–4 μM are likely a key vehicle for SARS-CoV-2 transmission [9], as they remain airborne for a prolonged period and can deposit in the distal airways. Recent data have shown that exertional respiratory activity, such as that seen in patients with COVID-19, increases the release of 1–4 μM respiratory aerosols, relative to conventionally defined “aerosol generating procedures” such as noninvasive respiratory support [10]. Patients in ICU are commonly at a later stage of disease and may shed less virus as a result. These data are consistent with our observations, suggesting that aerosol precautions may be more important in conventional wards than in well-defined “aerosol risk areas.”

The sampling and detection of airborne viruses poses several technological challenges, and there remains no agreed standard for their use or interpretation [11]. However, the detection of SARS-CoV-2 RNA by RT-qPCR (albeit at a high cycle threshold [CT] value), and the lack of detection during use of an air sterilization system, adds to a growing body of evidence implicating the airborne transmission of SARS-CoV-2 [1]. The detection of SARS-CoV-2 RNA in the air of a ward managing patients with COVID-19 intimates that this is a key mechanism by which healthcare professionals could become infected. The removal of airborne viral particles and other pathogens may help reduce the likelihood of hospital-acquired respiratory infections.

bar chart showing collated total number of bioaerosol detections during weeks 1 (filter off) and 2 (filter on) * $P = .05$ by Mann-Whitney *U* test. Top right: CT values of detected pathogens by high-throughput qPCR when filter switch on and off. Bottom: CT values for the single qPCR SARS-CoV-2 detection when filter switched on and off. NB: variation in CT values is a function of the microfluidics technology and do not reflect higher bioaerosol burdens. Abbreviations: CT, cycle threshold; ICU, intensive care unit; qPCR, quantitative polymerase chain reaction; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2.

This reduction may be by both decreasing the load of respirable particles and by removal of larger droplets that can facilitate fomite-associated spread [11]. The clearance of bioaerosol was not restricted to SARS-CoV-2. Although the impact of air filtration on nosocomial infection is uncertain [5, 12], the broad range of pathogens removed in this study suggests potential for benefit beyond SARS-CoV-2.

This study has limitations. The evaluation was conducted in 2 rooms, and there are no data defining the optimal air changes required to remove detectable pathogens with the specified devices, nor their impact in better ventilated facilities. Given the large volume of air within the room and the stability of viruses in the sampling fluid, it was predictable that the amount of SARS-CoV-2 detected would be minimal. However, negative results from the control sampler—and the striking but reversible effect of the air filtration devices—suggest these are not false positive detections, and we cannot exclude the risk of airborne infection. Future studies should examine whether air filtration devices have an impact on healthcare professional and patient focused outcomes, including measuring infection/exposure as an endpoint, as well as assessing potential harm, such as noise, reduced ambient humidity, or impact on delivery of care.

We were able to detect airborne SARS-CoV-2 RNA in a repurposed COVID-19 “surge ward” and found that air filtration can remove SARS-CoV-2 RNA below the limit of qPCR detection. SARS-CoV-2 was infrequently detected in the air of a “surge ICU”; however, the device retained its ability to reduce microbial bioaerosols. Portable air filtration devices may mitigate the reduced availability of airborne infection isolation facilities when surges of COVID-19 patients overwhelm healthcare resources and improve safety of those at risk of exposure to respiratory pathogens such as SARS-CoV-2.

Summary A comprehensive literature search of epidemiological studies and reports of transmissions of disease from feral pigeons to humans was performed. There were 176 documented transmissions of illness from feral pigeons to humans reported between 1941 and 2003. Feral pigeons harbored 60 different human pathogenic organisms, but only seven were transmitted to humans. Aerosol transmission accounted for 99.4% of incidents. There was a single report of transmission of *Salmonella enterica* serotype Kiambu to humans from feral pigeons, and no reports of transmission of *Campylobacter* spp. The most commonly transmitted pathogens continue to be *Chlamydia psittaci* and *Cryptococcus neoformans*. Although feral pigeons pose sporadic health risks to humans, the risk is very low, even for humans involved in occupations that bring them into close contact with nesting sites. In sharp contrast, the immunocompromised patient may have a nearly 1000-fold greater risk of acquiring mycotic disease from feral pigeons and their excreta than does the general population.

Introduction

High numbers of feral pigeons live in almost every large city in the world and they are frequently encountered by humans.¹ However, the health hazard that they pose has not been adequately assessed. Clinicians are confronted by the need to educate people about the risk of contracting disease most often when they are clearing feral pigeon excrements or culling them from buildings. However, many people have casual interactions with pigeons that range from feeding them in public parks to handling tamed birds that nest on window-sills. In addition, immunocompromised patients

need advice about limiting exposure to potential vectors of zoonotic diseases, even when it concerns seemingly innocuous traditions such as feeding pigeons in the park. Extermination that is intended to greatly reduce pigeons around human populations does not appear to work as well as restricting feeding,¹ are protested by those sensitive to the plight of animals, and most importantly, may pose increased hazards to human health from disturbance of the nesting environment and handling of carcasses. On the other hand, animal protection activists sometimes deny that pigeons pose any health hazard.² In spite of the large distribution of feral pigeons and their successful acclimation to humans, there are no reviews of the scientific literature on this topic. This paper aims to give clinicians information that will help them assess the risk to human health from feral pigeons.

Total 60 pathogens as designated by genus and species.

Methods

The review of older literature, which comprises sources not readily accessible to clinicians by standard scientific publication search engines, was accomplished by perusal of bibliographic references in Italian, French, German, Dutch and English publications (Tables 1 and 2). More recently cited sources were collected by searches with key words like 'pigeon', 'dove' and '*Columba livia*' in the medical database PubMed. Only those papers that showed confirmed, or in the case of one large outbreak presumptive diagnosis of disease in humans,³ are included in this review (Tables 1 and 2). All published reports of transmissions of pathogenic organisms from feral pigeons to humans were included for analysis and tabulation. For the review of food-related infections, the commodity term was used in conjunction with the terms 'food

and outbreak and human' (Table 3). Commodities chosen for comparison ranged from extremely common sources, such as milk to infrequently eaten specialty foods such as snake. For this evaluation, each publication was not perused individually for applicability to food related illness in humans, and thus, it only indicates relative frequency of reports of outbreaks for each commodity.

Results**Epidemiological investigations**

Seventy-seven epidemiological studies of feral pigeon populations identified human pathogenic organisms coming from 60 cities and regions. Analysis revealed that feral pigeons harbored a

total of 60 different human pathogenic organisms (Table 1). Five pathogens were viruses, nine were bacteria, 45 were fungi, and one was a protozoan (Table 1). However, only five pathogens were routinely transmitted to humans (Table 2). There were single case incidences for transmission of *Salmonella enterica* and *Toxoplasma* (Table 2). In general, there was a notable lack of transmission of pathogenic viruses and bacteria to people from feral pigeons.

Confirmation of the link between pigeons and fungal disease

There is a long-recognized link between pigeons and fungal diseases in humans, and, indeed, almost all (17 of 18) investigations of feral pigeon populations were positive for *Cryptococcus* spp. Review of the literature indicated that *Cryptococcus neoformans* and *Chlamydophila psittaci* were the most

widespread zoonotic pathogens in feral pigeon populations (Table 2). *C. neoformans* caused diseases in immunocompromised as well as in immunocompetent patients,⁴ but primarily in immunocompromised patients (Table 2). *C. neoformans* was acquired by 11 patients of whom seven were immunocompromised (Table 2). The Centers for Disease Control (CDC) reports that in the United States *Cryptococcus* spp. result in 0.2–0.9 cases per 100,000 in the general population per year.⁵ However, the CDC also reports that AIDS patients have a 1000-fold higher risk, with an annual reported incidence of 2–4 cases per 1000 persons.⁵ The pigeon is not an amplifying host of *Cryptococcus*, but its excrements offer an ideal environment for its growth.⁶ Therefore, it appears that the risk of illness associated with pigeons from *Cryptococcus* is now largely a function of the immune status of the human population rather than from people just having contact with birds. This is not a new concept,⁷ but the emergence of AIDS over the past 30 years and the associated increase in mycotic disease reiterates that a change in the human population rather than carriage rates by feral pigeons has occurred overtime. Similar to the situation with *Cryptococcus*, *Aspergillus* and *Candida* infections also appear to implicate a decline in human immune function as the primary risk factor for contraction of illness from feral pigeons (Table 2).

Chlamydia and *Histoplasma* infections in humans did not necessarily show an association with immunocompromise of the host (Table 2), although it cannot be ruled out without full knowledge of each individual case. An outbreak of *Chlamydophila psittaci* infection involved at least 35 persons and it was due to human contact with feral pigeons that

varied in intensity (Tables 1 and 2). According to the literature, *C. psittaci* has a worldwide average seroprevalence of 45.8% as determined by review of 33 epidemiological investigations. An earlier 1965 review suggested a seroprevalence of 28.7% in feral pigeon populations in different cities and regions.⁸ In preparation for this review, sampling of feral pigeons in Lucerne revealed a mean prevalence of 56% seropositive feral pigeons (H. Wackernagel, unpublished results). All investigations of feral pigeon populations have been seropositive for *C. psittaci* (Table 1), which suggests that this organism is commensally associated with the pigeon host. However, there was no evidence that a high prevalence rate in pigeons is necessarily associated with a high probability of infections in humans that encounter pigeons. Two reports describe infections in humans with *Histoplasma capsulatum* (Table 1), which was the pathogen associated with the highest number of cases in a single outbreak. Because all of the fungal pathogens, including *Cryptococcus*, *Chlamydophila*, and *Histoplasma*, are known to be transmitted by inhalation of aerosolized organisms, the data suggests that 175 of 176 (99.4%) of described transmissions resulted from airborne excreta, which includes dried feces, ocular discharges, and crop milk.⁹ However, other methods of transmission are possible if close contact occurs, as evidenced by one report of primary cutaneous cryptococcosis of a HIV-positive drug abuser following injury inflicted by a feral pigeon (Table 1). Contact is sometimes brief, and the patient does not always recall any encounter with birds.⁹

Pigeons are not reported to be a common source of food-borne illness

Only two reports describe transmission of *Salmonella enterica* (*S. enterica*) to humans from either domesticated or feral pigeons, one of which occurred outside the general time frame of 60 years for this review. Illness in 20 soldiers in the Dutch army occurred in 1933 that clearly implicated *S. enterica* serovar Typhimurium variant Copenhagen as the causative agent that contaminated lemon pudding made with eggs from domestic pigeons.¹⁰ It appears to be the only case of food-borne transmission from pigeons to humans in the literature. Feral pigeons resulted in a case of salmonellosis from *S. enterica* serovar Kiambu¹¹ (Table 2). Given that *S. enterica* serovar Typhimurium variant Copenhagen and *Campylobacter*, which are common food-borne pathogens, are frequently recovered from feral pigeons as well as from domesticated pigeons used for food,¹²⁻¹⁷ it

is surprising that there are no other reports of food-borne transmission to humans from pigeons in the literature.

To pursue the idea further that there is a low risk of transmission of common food-borne bacteria between pigeons and humans, an independent risk assessment was performed. A feral pigeon population of around 5000-8000 birds that was sampled in Basel, Switzerland in preparation for this review harbored *C. psittaci*, *Campylobacter* spp., *S. enterica* serovar Typhimurium variant Copenhagen, and *Aspergillus fumigatus* (Haag-Wackernagel, unpublished data). However, records from the Department of Internal Medicine of the University Hospital in Basel showed that there were no direct transmissions of disease from feral pigeons to humans between 1997 and 2003 (Flueckiger and Haag-Wackernagel, unpublished data). In addition, a search of the literature revealed that, other than the 1933 outbreak, there were no reports of food-borne illness from either domesticated or feral pigeons since 1933 (Table 3). This finding is unexpected given that contact between pigeon and human is a frequent occurrence as compared to what probably happens with wild boar, snake, ostrich and alligator (Table 3). Illness was noted to occur in the literature base for rabbit, which is another feral animal that is sometimes domesticated and bred for food and kept as a pet. Therefore, it appears that the risk of transmission of food-borne disease from pigeon to human is comparatively low, in spite of pigeons being frequent carriers of common food-borne pathogens.

Other suggested associations between pathogens and feral pigeons

One case of *Toxoplasma gondii* is reported (Table 1), which occurred in an elderly woman. Therefore, all immunocompromised patients, including pregnant women who are at higher risk for contracting toxoplasmosis, should be advised to avoid feral pigeon populations and their nesting sites. Currently, there is no experimental evidence that pigeons are an important vector for the recently emerged viral disease of human pathogenic avian influenza¹⁸ and the epidemiological association between feral pigeons and humans in regards to this disease is only speculative.¹⁹ Although it appears that feral pigeons are seropositive for West Nile virus, there is no epidemiological evidence that they are an amplifying vector as are crows.²⁰⁻²²

Discussion

Epidemiological screening programs of animal reservoirs often identify pathogens that have never been, or are seldom, transmitted to humans. In regards to zoonotic disease transmitted from the feral pigeon to humans, all viruses, *Yersinia*, *Salmonella*, *Campylobacter* and *Toxoplasma* are in this category. Therefore, the results of many of the epidemiological investigation herein reviewed were only relevant for assessing the health of the feral pigeon populations rather than for assessing their hazard to human health. Thus, the mere isolation of a pathogen from pigeons does not justify their extermination, although people should be educated about the risk factors for acquiring mycotic disease. The low number of 176 reported transmissions in the literature that spans approximately 60 years underestimates risk, because many cases are not published or the sources of the infections are not recognized. However, in spite of the worldwide distribution of feral pigeons, the close and frequent contact they have with humans, their use as food, and the high prevalence of carriage of human pathogens, zoonotic disease caused by feral pigeons is infrequent. Healthy people who are exposed to feral pigeons and their nesting sites, or who have increased exposure from hobbies or occupations involving feral and domesticated pigeons, should be informed of these risks and advised of appropriate ways to protect themselves. These methods include wearing coveralls, face masks, other respiratory protection, washing hands and by disinfection against excreta dust with antiseptics. If possible, sick pigeons should be avoided, or at the very least, handled with great care to prevent exposure to excreta. The literature reiterates that the immunocompromised patient is at considerably higher risk for contracting opportunistic disease from feral pigeon populations. Since opportunistic pathogens have a multitude of vectors besides feral pigeons, disease prevention is probably best attained by educating the immunocompromised patient to limit contact with all avian sources and to follow guidelines for maintaining hygiene under any circumstance where close contact with pathogenic organisms might occur.

Exposure to bacterial and fungal bioaerosols in facilities processing biodegradable waste

Merja H. Kontro¹, Maija Kirsi² and Sirpa K. Laitinen^{3*}

¹Ecosystems and Environment Research Programme, University of Helsinki, Helsinki, Finland, ²Work Environment Laboratories, Finnish Institute of Occupational Health, Helsinki, Finland, ³Department of Occupational Safety, Finnish Institute of Occupational Health, Helsinki, Finland

The aim of the study was to determine the exposure of workers within biodegradable waste processing facilities to bacteria and fungi to identify any exposures of potential concern to health. Occupational measurements were performed in six composting and three bioenergy (bioethanol or methane/biogas) producing facilities. Bioaerosols were measured from breathing zones with Button aerosol or open face cassette filter samplers, and swab specimens were taken from the nasal mucous membranes of the workers. *Aspergillus fumigatus*, *Bacillus cereus* group, *Campylobacter* spp., *Salmonella* spp., *Streptomyces* spp., and *Yersinia* spp. were determined by real-time polymerase chain reaction (qPCR). *A. fumigatus*, and mesophilic and thermophilic actinobacteria were also cultivated from filters. Bacterial airborne endotoxins collected by IOM samplers were analyzed using a *Limulus* assay. Bioaerosol levels were high, especially in composting compared to bioenergy producing facilities. Endotoxin concentrations in composting often exceeded the occupational exposure value of 90 EU/m³, which may be harmful to the health. In addition to endotoxins, the concentrations of *A. fumigatus* (up to 2.4 × 10⁵ copies/m³) and actinobacteria/*Streptomyces* spp. (up to 1.6 × 10⁶ copies/m³) in the air of composting facilities were often high. Microbial and endotoxin concentrations were typically highest in waste reception and pre-treatment, equal or decreased during processing and handling of treated waste, and lowest in wheel loader cabins and control rooms/outdoors. Still, the parameters measured in wheel loader cabins were often higher than in the control sites, which suggests that the use of preventive measures could be improved. *B. cereus* group, *Salmonella* spp., and *Yersinia* spp. were rarely detected in bioaerosols or nasal swabs. Although *Campylobacter* spp. DNA was rarely detected in air, as a new finding, *Campylobacter ureolyticus* DNA was frequently detected in the nasal mucous membranes of workers, based on partial 16S rDNA sequencing. Moreover, especially *A. fumigatus* and *C. ureolyticus* spp. DNA concentrations in swabs after the work shift were significantly higher than before the shift, which indicates their inhalation or growth during the work shift. Microbial qPCR analysis of bioaerosols and swab samples of nasal mucosa allowed measuring exposure in various work operations and during the work shift, identifying problems for health risk assessment to improve working conditions, and evaluating the effectiveness of preventive measures and personal protection of workers.

KEYWORDS

bioaerosols, bacteria, exposure assessment, fungi, microbial DNA, urban waste management

Introduction

Microorganisms in biodegradable waste can cause infections, acute toxic effects, allergies, and cancer, which has been considered as a serious health problem in the increased recycling of waste material (1). The most common route of entry for biological hazards is inhalation as bioaerosols. Workers may be exposed to bioaerosols when microorganisms are released into the air during the handling of waste. Exposure to bioaerosols in waste management is associated with a wide range of health effects. According to interviews and follow-up studies, workers in the waste management sector experience more work-related symptoms and illnesses than other occupational groups (2, 3). Respiratory symptoms and lung impairment are the most widely studied and probably among the most significant bioaerosol-associated health effects. In particular, the aerobic treatment of waste in composting facilities is associated with adverse acute and chronic respiratory health effects for workers, such as pulmonary irritation and inflammation, chronic bronchitis, and occupational asthma (4–6).

The assessment of exposure to bioaerosols has traditionally been performed using culture-based methods. They are suitable for the simultaneous identification of many different species and are sensitive enough to detect spores of fungi and actinobacteria. However, cultivation is of limited utility in the quantitative assessment of exposure to many pathogens due to non-cultivability or even loss of viability, although cellular components may still induce adverse effects. In addition, pathogenic microbes can be hazardous at extremely low levels that cannot be detected by culture-based methods. Molecular-based diagnostic techniques have much better sensitivity than classical culture-based methods (7, 8). In the real-time polymerase chain reaction (qPCR) method, microbial deoxyribonucleic acid (DNA) as a cell component is a marker for the specific and rapid detection of microorganisms.

The nose is the primary entry route for inhaled air, and the first region of the respiratory tract to come into contact with bioaerosols. Therefore, qPCR detection combined with nasal samples from workers' mucous membranes could be used as a tool to assess exposure to airborne bacteria and fungi in waste management. PCR assays in studies of respiratory viruses and bacteria have provided similar results from both anterior nasal swab specimens and samples collected by nasopharyngeal aspiration (9, 10). Previous studies of nasal fungal and bacterial findings in occupational environments are scarce. Alsaleh et al. (11) have found mold in some nasal samples, when studying respiratory viruses in infants, despite using commercial swab tubes with antifungal agents. They speculated that the fungal findings were due to factors in the living environment of the infants. Furthermore, the carriage of livestock-associated methicillin-resistant *Staphylococcus aureus* to pig farmers and healthcare workers has been demonstrated (12, 13). Mbareche

et al. (14) have shown correlation between the nasopharyngeal bacterial flora of swine workers and the biodiversity of swine barns bioaerosols. These studies demonstrate the transfer of microbes from the work environment to workers via inhalation.

Against the above background, the presence of endotoxins, and airborne microorganisms in composting and bioenergy facilities processing biodegradable waste, and then in the nasal mucous membranes of workers was investigated by cultivation and/or qPCR, with species identification by sequencing when necessary. *A. fumigatus* was measured as an indicator of workers' exposure to fungi, as it is a well-known cause of infectious mycoses, such as bronchopulmonary aspergillosis (15). Actinobacteria of the genus *Streptomyces* are Gram-positive bacteria, which produce resistant spores that can be infectious. Actinobacteria can promote the development of respiratory diseases together with fungi (16). *Bacillus cereus* group, *Campylobacter*, *Salmonella* and *Yersinia* species can be pathogenic bacteria especially in animal waste (17–20). The hypothesis of this study was that waste management workers become exposed to fungal and bacterial pathogens when inhaling bioaerosols through the nose, while the null hypothesis was that no exposure occurs when preventive measures are used. The relevance of the study was to characterize bacterial and fungal exposures for health care, which would lead to improved guidance in waste management companies, where the recycling of waste material is constantly increasing.

Materials and methods

Description of studied facilities

The occupational environments in which this study was conducted were six full-scale composting facilities, and three biogas or bioethanol producing facilities in Finland. Composting is an aerobic treatment in which organic biodegradable waste is recycled into soil fertilizer. Bioenergy facilities produce renewable energy from waste, after which the organic material can be further recycled into soil fertilizer or landscaping. Biogas, mainly a mixture of methane and carbon dioxide, is produced in waste management by anaerobic digestion, and bioethanol by waste fermentation. The facilities treated waste consisting of source-separated municipal biowaste, organic by-products from various agricultural and industrial (bakery, dairy, sugar production) processes, animal manure, and/or wastewater sludge. In the facilities, the transfer of biomass from one site to another was done with wheel loaders equipped with cabins to protect workers. The early stages of composting were indoors, followed by maturation in outdoor windrows (21). Sampling was performed in waste reception and pre-treatment, processing facilities, handling of treated waste, and then in areas with increased protection, including wheel loader cabins, control rooms, dining areas, and outdoors (field edges, parking sites).

Sample collection

Bioaerosol samples from work environments were collected from different stages of the waste treatment processes at fixed measuring points approximately 1.5 m above the floor as close as possible to the process, from the workers' breathing zone, and from the wheel loader cabins. Reference samples were taken from presumed clean and safe work environments, such as a control room or outdoor air, at a distance of more than 300 m upwind from the composting area.

Bioaerosols were measured from workers breathing zones using a filter collection (22). Inhalable bioaerosols for cultivation (18–25 samples/microbe) and qPCR (44 samples) analyses were collected using a Button Aerosol Sampler (SKC Inc., Eighty-Four, PA, USA) at a calibrated flow rate of 4 liters/min in a sample pump with mixed cellulose ester filters (MCE, 1.2 μm , Ø 25 mm, SKC Inc.). The volumes of air samples collected ranged from 0.22 to 1.05 m³, the sampling time being the same as the duration of the work phase. In addition, inhalable bioaerosols were collected for cultivation (20–27 samples/microbe) and qPCR (65 samples) using open face cassettes with polycarbonate filters (PC, 0.4 μm , Ø 37 mm, Whatman International Ltd., Kent, UK) at a calibrated flow rate of 2 liters/min. The volumes of collected air samples varied between 0.11–0.54 m³ depending on the duration of the work. PC and MCE filters used for microbial cultivations were processed within 24 h of sampling, while filters used for qPCR analyses were stored at -80°C until analysis.

Altogether 48 nasal mucous membrane samples from both nostrils of 19 workers (27 samples from composting facility workers and 21 samples from researchers collecting the samples) were taken with nylon flocked swabs (Copan Innovation, Brescia, Italy), first in the morning from the nose of 17 workers, and then after the work shift in the afternoon from the nose of 31 workers. Parallel samples were taken from both nostrils. The swabs were rotated inside the nostril against the internal anterior walls and then placed in the provided transport tube. The swabs were stored at -80°C until qPCR analysis of bacteria and fungi.

All procedures involving humans, including environmental sampling, were conducted in accordance with the ethical standards of the institutional or national research committee, and the 1964 Declaration of Helsinki and its subsequent amendments or comparable ethical standards. The Ethics Committee of Helsinki University Hospital approved the study protocol (HUS/41/13/03/00/2011). All participants provided written informed consent prior to their participation.

Microbial cultivations

Viable bacteria and fungi were cultivated for 3–14 days at specified temperatures on the following culture media. Thermotolerant fungi were cultivated on Rose Bengal (Hagem)

agar (PC filter, 19 samples; MCE filter, 19 samples; $40 \pm 3^{\circ}\text{C}$); thermophilic actinobacteria on half-strength nutrient agar (PC filter, 23 samples; MCE filter, 18 samples; $55 \pm 3^{\circ}\text{C}$); and mesophilic actinobacteria (*Streptomyces* spp.), and other bacteria on tryptone-yeast extract-glucose agar (PC filter, 26 samples; MCE filter, 25 samples; $25 \pm 5^{\circ}\text{C}$) (23–25). After the incubation period, colonies were counted, and *Aspergillus fumigatus* and *Streptomyces* spp. were identified by microscopic examination of morphology. Concentrations of viable microorganisms in bioaerosols were expressed in cfu/m³ (colony forming units per cubic meter of air).

Measurement of endotoxins

All gram-negative bacteria in the waste contain components called endotoxin in their cell walls. In this study, four parallel endotoxin samples were collected from air at 55 different sampling points using an IOM Sampler (SKC Inc.) at a flow rate of 2 liters/min (26). Biologically active endotoxins in air samples were measured using a validated kinetic chromogenic *Limulus* amoebocyte lysate (LAL) assay (Kinetic QCL, Lonza, Walkersville, MD, USA). The collected glass fiber filters (1.0 μm , Ø 25 mm, SKC) were extracted with 5 ml of non-pyrogenic water for 1 h, after which the extracts were centrifuged at 1,000 $\times g$ for 15 min. Supernatants were diluted 1:25 (vol/vol) and analyzed in duplicate for the presence of endotoxin. Standard curves were performed by reconstituting the endotoxin standard of *Escherichia coli* O55:B5 in non-pyrogenic water. The spiked samples were analyzed to determine if inhibition or enhancement affected the endotoxin assay. Results were expressed in EU/m³ (endotoxin units per cubic meter of air).

Real-time PCR

Real-time polymerase chain reaction (qPCR) was used to detect the DNA from cultivable and non-cultivable cells of *A. fumigatus*, *Bacillus cereus* group, *Campylobacter* spp., *Streptomyces* spp., *Yersinia* spp., and *Salmonella* spp. using the same experimental schemes as described in Rainisalo et al. (21). Bacterial and fungal DNA was isolated using the PowerSoil[®] DNA Isolation Kit according to the manufacturer's instructions (Mo Bio Laboratories Inc., Carlsbad, CA, USA). A swab or filter was transferred to the PowerBead tubes instead of soil. Tubes were incubated at 70°C for 10 min to inactivate DNases, followed by cell lysis for 3.5 min at 50 Hz using a TissueLyser LT bead mill (Qiagen, Valencia, CA, USA).

To monitor *A. fumigatus*, a 136 bp fragment of rDNA internal transcribed spacer 1 region was detected using primers AfumiF1 (5'-GCCCGCCGTTTCGAC-3'),

AfumiR1 (5'-GTTGTTGAAAGTTTAACTGATTAC-3') and probe AfumiP1 (5'-CCCCCGAAGACCCCAACA TG-3') (27). *B. cereus* group was followed using primers Pf 5'-GAGTTAGAGAACGGTATTTATGCTGC-3' and Pr 5'-CTACTGCCGCTCCATGAATCC-3', which detect 409 bp fragment of the cereolysin A gene (17). *Campylobacter* spp. (primers C412F, 5'-GGATGACACTTTTCGGA GC-3'; and C1228R, 5'-CATTGTAGCACGTGTGTC-3'; fragment size 816 bp) (18), *Streptomyces* spp. (primers StrepB, 5'-ACAAGCCCTGGAAACGGGT-3'; StrepE, 5'-CACCAGGAATTCCGATCT-3'; fragment size 519 bp) (21, 28), and *Yersinia* spp. (primers Y.16S-86f, 5'-GCGGCAGCGGGAAGTAGTTTA-3'; B.16S-794r, 5'-TACAGCGTGGACTACCAGGT-3'; fragment size 749 bp) (20) were monitored using PCR primers that detect the 16S ribosomal ribonucleic acid (rRNA) gene (16S rDNA). To detect the *Salmonella* species, primers 139 (5'-GTGAAATTATCGCCACGTTTCGGGCAA-3') and 141 (5'-TCATCGCACCGTCAAAGGAACC-3') were used to amplify a 284 bp fragment from the invasion A gene (19). The detection limits based on the lowest positive results were ≤ 7 copies/PCR, corresponding to 101–1,853 copies/swab, and 890–4,069 copies/m³ depending on the filtered air volume. Internal amplification controls (IAC) were from kits designed for the microbes studied and purchased from Okepem Ltd (Finland).

The 20 μ l PCR reaction mixture contained each primer: 0.5 μ M (0.1 μ M probe; *A. fumigatus*)/0.1 μ M (*B. cereus* group)/0.4 μ M (*Campylobacter* spp.)/0.4 μ M (*Streptomyces* spp.)/0.23 μ M (*Yersinia* spp.)/0.4 μ M (*Salmonella* spp.); 1x DyNamoTM HS SYBR Green qPCR Kit (contained hot start version of modified *Tbr* DNA polymerase, SYBR Green 1, optimized PCR buffer, 2.5 mM MgCl₂, dNTP mixture) (Thermo Fisher Scientific Inc., Waltham, MA, USA); 2 μ l of template DNA; and 1 μ l of IAC. Real-time PCRs were performed using iQ5 Real Time PCR Detection System (Bio-Rad Laboratories, Hercules, CA, USA). At least four real-time PCR analyses were performed on at least two DNA isolations from filters and swabs. Controls in duplicate for each PCR experiment were as follows: reagents without template DNA and IAC (no amplification); reagents and IAC without template DNA (IAC amplified); and seven quantification standards in duplicate. The result was evaluated as negative when, according to melting curve analysis, the IAC was amplified without the product of the microbial primers.

To confirm the occurrence of *Campylobacter* spp. in the nasal samples, the amplified 16S rDNA sequences were sequenced as a purchased service at a DNA sequencing laboratory (Institute of Biotechnology, University of Helsinki, Finland) as presented in Pukkila et al. (29). The 16S rDNA sequences were compared to those in the gene library using the Fasta program. The 16S rDNA sequence accession numbers are OP432221-OP432236.

Statistical analyses

Data were analyzed using SPSS Statistics for Windows, version 28.0.0.0 (IBM Corporation, Chicago, IL, United States). Endotoxin concentrations, and microbial DNA copy numbers were statistically analyzed using two-factor (operation, type of facility) Kruskal-Wallis test (KW) followed by pairwise comparisons using Mann-Whitney test (MW). Cultivated microbial numbers in composting facilities were analyzed by one-factor (operation) KW test followed by MW test. Differences in DNA copy numbers due to sampling methods; due to the high-efficiency particulate air (HEPA) filtration systems; before and after the work shifts; and in nasal swabs between facilities types were analyzed by MW. Differences in colony-forming units of *A. fumigatus* and actinobacteria due to sampling methods (Button aerosol or open face cassette filter samplers) were analyzed by *t*-test. Non-parametric statistical analyses were used, if the equality of variances (Levene's test) and/or normal distribution (Kolmogorov-Smirnov test) were not fulfilled. Pearson's two-tailed correlations for positive logarithmic values of colony-forming units and copy numbers were calculated.

Results

Endotoxins, and cultivated *A. fumigatus* and actinobacteria in bioaerosols

Endotoxin concentrations in bioaerosols were high, especially in composting operations compared to bioenergy (biogas or ethanol) producing facilities (KW/MW $p \leq 0.004$; Table 1). Air endotoxin levels in the waste reception and pre-treatment were higher than during waste processing, and in wheel loader cabins and control sites (KW/MW $p \leq 0.034$). The highest air endotoxin concentration of 16,000 EU/m³ was measured during the handling of the treated waste. However, the variation of air endotoxin concentrations was large during waste handling ($< \text{LOD}$ –16,000 EU/m³), which is why this process stage did not differ significantly from the other operations. Air endotoxin concentrations in the wheel loader cabins ranged from below the detection limit to 33 EU/m³, with the exception of two poorly protected cabins with levels ranging from 1,600 to 8,400 EU/m³. Endotoxin concentrations in the air clearly exceeded the occupational exposure limit value of 90 EU/m³ in all studied composting facilities. In biogas facilities, this limit value was exceeded only once in indoor waste reception and pre-treatment.

High numbers of *A. fumigatus* (up to 5.7×10^5 cfu/m³) and actinobacteria (up to 2.5×10^6 cfu/m³) were cultivated from composting facility air samples, regardless of sampling method (*t*-test, $p \geq 0.378$; Button aerosol vs. open face cassettes; Table 1). *A. fumigatus* numbers in the air of composting facilities

Samples were collected from waste reception and pre-treatment, processing, handling of treated waste, wheel loader cabins, and control rooms/outdoors; number of samples in parentheses. Superscript numbers indicate significant differences between composting and bioenergy production, and superscript letters show significant differences between operations (Kruskal-Wallis/Mann-Whitney, $p \leq 0.05$).

ND, Not determined.

were highest in waste reception and pre-treatment and during processing, while significantly lower counts were cultivated from the air of wheel loader cabins, and control rooms/outdoors (MW, $p \leq 0.040$). Similarly, thermophilic actinobacteria in the air of the composting facilities were most abundant in waste reception and pre-treatment, and also during processing, while significantly lower numbers were cultivated from the handling of treated waste, wheel loader cabins, and control rooms/outdoors (KW/MW, $p \leq 0.040$). The concentrations of mesophilic actinobacteria in the air of the composting facilities were highest in waste reception and pre-treatment compared to lower quantities during waste processing and handling of treated waste, and in wheel loader cabins (KW/MW, $p \leq 0.040$). In contrast, *A. fumigatus* could not be cultivated from the air of bioenergy facilities, and the numbers of mesophilic actinobacteria were low (81–499 cfu/m³).

Microbial DNA in bioaerosols

The results of the qPCR assays correlated very well with the results obtained with culture-based methods for the identification and quantification of *A. fumigatus* ($R = 0.696$, $p < 0.001$, $n = 25$) and *Streptomyces* spp. (mesophilic actinobacteria $R = 0.778$, $p < 0.001$, $n = 33$; thermophilic actinobacteria $R = 0.620$, $p < 0.001$, $n = 27$) from air samples collected with a Button or open face cassette aerosol sampler. The air sampling method did not affect the DNA copy number results of any microbes (MW, $p \geq 0.084$, Button aerosol vs. open face cassettes). *A. fumigatus* (up to 2.4×10^5 copies/m³) and *Streptomyces* spp. (up to 1.6×10^6 copies/m³) DNA levels were of the same order of magnitude as the concentrations of cultivable microbes in bioaerosols, and their levels in composting facilities were higher than in bioenergy production (KW/MW, $p < 0.001$; Table 1). No *A. fumigatus* gene copies were detected in the air of bioenergy producing facilities, and *Streptomyces* spp. DNA was only found at the waste reception and pre-treatment.

The number of *A. fumigatus* gene copies in composting facilities was highest in waste reception and pre-treatment, lower and about equal during processing and handling of treated waste, low in wheel loader cabin, and lowest in control room/outdoors (KW/MW, $p \leq 0.037$; Table 1). In composting facilities, *A. fumigatus* DNA levels in well-sealed wheel loader cabins equipped with pressurization and high-efficiency particulate air (HEPA) filtration system were lower than in other wheel loaders equipped with poorly designed equipment (MW, $p = 0.012$). The highest *Streptomyces* spp. DNA copy levels in composting facilities were also observed in waste reception and pre-treatment, lower concentrations were detected during waste processing and handling of treated waste, and in wheel loader cabins, while numbers were lowest in control rooms/outdoors (KW/MW, $p \leq 0.004$).

DNA from *B. cereus* group, *Campylobacter* spp., *Salmonella* spp., and *Yersinia* spp. was rarely detected in air samples from composting and bioenergy producing facilities (Table 1). *B. cereus* group and *Yersinia* spp. DNA was detected once, and *Salmonella* spp. DNA was detected twice in the waste reception and pre-treatment air of composting facilities. *Yersinia* spp. DNA was detected in the air once during compost processing, and twice during handling of treated compost waste. *B. cereus* group and *Yersinia* spp. DNA was detected in the air from the same wheel loader cabin where the highest endotoxin concentration was measured, while *Campylobacter* spp. DNA was found in two other wheel loader cabins at the composting facilities. The DNA of these bacteria was not detected in the control rooms or outdoor. In bioenergy facilities, *Campylobacter* spp. and *Yersinia* spp. DNA was detected only once in waste reception and pre-treatment.

Microbial DNA in nasal samples

As the qPCR analysis of microbial DNA proved to be a reliable assay for air samples, the same methods were used to analyse nasal swabs. These samples were taken from the noses of 19 workers and sampling researchers before and after the work shift. In the composting facilities, *A. fumigatus* DNA was detected in the nasal swab samples of 9 workers after the work shift, and in only two samples before the work shift, the difference being statistically significant (MW, $p = 0.042$; Table 2). In the bioenergy producing facilities, nasal samples were taken from 10 workers, and only one worker produced a positive nasal finding for *A. fumigatus* DNA.

More workers in composting facilities had positive *Streptomyces* spp. DNA findings than in bioenergy facilities (MW, $p = 0.020$; Table 2). A positive result was also observed in most composting plant workers at the beginning of the shift, but the mean amount of *Streptomyces* spp. DNA was about 4-fold higher after the work shift. In composting facilities, 8 positive results for *Streptomyces* spp. DNA were obtained from 16 nasal samples taken before the work shift, while the number of positive swab specimens after the shift was 18 out of 22. In bioenergy facilities, the proportion of positive *Streptomyces* spp. DNA swab samples was only three out of ten nasal samples.

The number of workers with a positive *Campylobacter* spp. DNA nasal sample was 17 of the 27 studied, although *Campylobacter* species were detected in only three air samples. Of these workers, 19 worked in composting facilities and 14 of them has a positive nasal sample. The quantities of *Campylobacter* spp. DNA in nasal samples after the work shift were significantly higher than before the shift (MW, $p = 0.029$; Table 2). Altogether 15 partial *Campylobacter* spp. 16S rDNA sequences were sequenced from nasal swab samples. All sequences were 99.9–100.0 % identical to the *Campylobacter ureolyticus* sequence. Partial 16S rDNA sequence

of *Campylobacter* sp. DNA in an air sample from biogas production from pig manure was 99.9 % identical to the DNA of *Campylobacter lanienae* strain 15991b.

Yersinia spp. DNA was detected in the nose of only one worker, and no *B. cereus* group or *Salmonella* spp. DNA was found in nasal swab samples (Table 2).

Discussion

Microbial bioaerosols in air

Biodegradable waste provides a favorable substrate for microorganisms to live and reproduce. These microorganisms can be spread into the air by physically handling the waste, and a large portion of the bioaerosols can be present in the ambient air, as the results showed (Table 1). Bioaerosols formed from waste at composting facilities contained large amounts of mesophilic and thermophilic actinobacteria (*Streptomyces* spp.) and thermotolerant fungi (*A. fumigatus*), all of which play an important role in the transformation processes occurring during organic material decaying (30). Fungi of the genus *Aspergillus*,

and actinobacteria have often been identified as dominant species at different stages of composting, often in the same quantities as measured in this study (7, 31–34). However, in this study, *A. fumigatus* was not detected in bioenergy facilities, although previously up to 1.2×10^4 ITS genes/m³ have been detected mainly in waste reception and shredding, as well as in storage and output sites (35).

DNA of the other studied bacteria, *B. cereus* group, *Campylobacter* spp., *Salmonella* spp., and *Yersinia* spp., was detected in the air only rarely, more often in composting than in bioenergy facilities (Table 1). Nevertheless, *Bacillus* has been reported to belong to the dominant genus in compost bioaerosols (36, 37). In bioenergy facilities, *Yersinia* spp. DNA was detected only once in the air from the waste reception and pre-treatment simultaneously with *Campylobacter* spp. DNA. In composting facilities, *B. cereus* group, *Campylobacter* spp., *Salmonella* spp., and *Yersinia* spp. DNA was detected only in operations involving compost turning, either in the air of the composting space or in poorly protected wheel loader cabins. The concentrations of all studied microorganisms in the bioaerosols of the composting facilities were the highest in waste reception and pre-treatment, and among the lowest in the handling of treated waste, where concentrations could still be quite high. This is consistent with previous results, where bioaerosol concentrations have been highest during on-site agitation activities, such as turning, screening, and shredding (3).

In connection with microbial counts, it is important to recognize that only a small portion of microorganisms are cultivable or viable under bioaerosol sampling and culture conditions, resulting in lower numbers of colony-forming units than the actual total number of microbes. At the same time, large quantities of harmful biologically active cell components, such as endotoxins, can remain in the bioaerosols of composting operations (7, 8). Identification of common composting biomarkers and the causal relationships between bioaerosol exposure and disease outbreaks, as well as defining exposure limits are future requirements (8, 38). As large variations in microbial numbers were observed in this study, in agreement of other published results (3), it may be utmost important to recognize that the quality and treatment history of the waste material affects the microbial numbers and bioactive component quantities in bioaerosols. As unit operations in waste treatment can be difficult to standardize reliably, health risk assessment should be based on the highest commonly occurring concentrations in each operation.

In this study, bioaerosol levels were much higher in composting than in biogas or bioethanol producing facilities (Table 1). Dubuis et al. (39) have also shown that human exposure to bioaerosols in biomethanization facilities is lower than in composting plants. No legally binding limit values have been established for occupational exposure to bioaerosols (8, 38). However, data obtained from the assessment of occupational

exposure to endotoxins, which serves as a marker for the whole group of Gram-negative bacteria, indicate that adverse health effects can be expected after chronic exposure to concentrations above 90 EU/m³ (40). The highest endotoxin concentrations (up to 16,000 EU/m³) were measured when compost was turned (Table 1), which is known to increase bioaerosol production (32). These results support previously published data suggesting that composting site workers may be exposed to high levels of bacterial endotoxins and microbial bioaerosols (31, 39, 41, 42).

Bioaerosols are a health risk, especially when waste is handled openly in the proximity of workers (32). Working inside a sealed cabin with air filtration had a major impact on reducing exposure to bioaerosols. Schlosser et al. (43) have found that, in particular, a pressurization and HEPA filtration system in the vehicle cabins of composting facilities can provide more than 99.9% protection efficiency. Their study emphasized that vehicle cabin protection systems reduced airborne endotoxins more than fungal spores. A similar observation was also found in this study that endotoxins were easier to remove than actinobacteria and fungi from the interior air of the cabins (Table 1). Regardless of the measurement methods, the concentrations of *A. fumigatus* and actinobacteria in the wheel loader cabins of the composting facilities were always significantly lower than in waste reception and pre-treatment. Still, the concentrations of endotoxins, as well as *A. fumigatus* and *Streptomyces* spp. DNA in wheel loader cabins were often higher than in control rooms or outdoors, suggesting that the hygiene could be better maintained.

Microbial DNA in nasal samples

Composting plant workers had more *A. fumigatus* and *Campylobacter* spp. DNA in nasal samples after the work shift than before the shift. The difference in *Streptomyces* spp. DNA concentration in nasal samples before and after the work shift was less clear than the difference in *A. fumigatus* DNA. Most of the workers in composting plants had *Streptomyces* spp. DNA in the nose already at the beginning of the work shift. This means that workers may have been exposed to *Streptomyces* spp. elsewhere. Another possible explanation is that the concentrations of *Streptomyces* spp. DNA in the air (up to 2.5 × 10⁶ cfu/m³) and compost (21) in some waste handling operations were so huge that the nasal cells did not have enough time to disinfect the bacteria on the nasal mucous membranes between work shifts.

The most surprising result of this study was that *Campylobacter* spp. DNA was very common in the nasal mucous membranes of workers at composting facilities processing biodegradable waste. *Campylobacter* spp. 16S rDNAs were sequenced to confirm their occurrence, and the most common species was *C. ureolyticus*. In Southern Ireland, molecular studies on the prevalence of various *Campylobacter*

spp. in patients with gastroenteritis have identified *C. ureolyticus* as the second most common *Campylobacter* species (44). In other studies, this strain has been isolated from a wide variety of human samples, including superficial ulcers and soft tissue infections, urethritis, periodontal disease, and human feces (45, 46). *C. ureolyticus* has also been detected in the direct sequencing of 16S rDNA from template DNA isolated from human skin (47–49).

Campylobacter spp. DNA was detected in an air sample at a biogas plant processing pig manure. The 16S rDNA sequence of *Campylobacter* sp. in this air sample differed from those observed in the nasal swab samples. The bacterial DNA in the air sample was identical to *Campylobacter lanienae* DNA previously isolated from food-producing swine (50). Airborne cultivable *Campylobacter* spp. could not be recovered from bioaerosol samples in another agricultural study, although four of the 35 nasal flora samples from hog producers were *Campylobacter* spp. positive (51). The reason for this rare occurrence of *Campylobacter* spp. in air samples could be that, as preferentially anaerobic bacteria, they are easily destroyed in the air, especially during sampling. In this study, *Campylobacter* spp. DNA levels in air samples were low, close to the detection limit of 1.2 ± 0.6 × 10³ copies/m³ (1–5 copies/PCR). The workers may also have been exposed to *Campylobacter* spp. through skin contact with contaminated hands. Human campylobacteriosis is commonly considered to be a zoonotic disease with infection transfer being mainly mediated via the fecal-oral route (52). Exposure to bioaerosols may have promoted the nasopharyngeal growth of *C. ureolyticus* naturally present in the body, if not derived from bioaerosols.

Whether or not *Campylobacter* spp. are the leading cause of intestinal infections among workers in the waste management sector requires further studies. It is known that *Campylobacter* spp. are the major cause of foodborne diarrheal diseases in humans, and among the most common bacteria causing gastroenteritis worldwide (52). In both developed and developing countries, they cause more cases of diarrhea than *Salmonella* spp. (53). Therefore, *Campylobacter* species must be more common in the environment than is known. Our study, and new data from other studies suggest that *C. ureolyticus* is an emerging *Campylobacter* strain whose clinical importance is still underestimated (45).

DNA findings of other pathogens in nasal samples were sporadic compared to *Campylobacter* spp. DNA. *Yersinia* spp. DNA was detected in the nose of only one worker, who also had high numbers of *Yersinia* spp. DNA in the breathing zone in the cabin, collected by the air filter. In previous studies, *Yersinia enterocolitica* has been infrequently detected in both bioaerosols (2/18) and nasal secretions of hog producers (1/35) (51).

Detection of bioaerosols by the molecular qPCR assay was a sensitive method to assess workers exposure. Using nasal swabs in combination with the qPCR assay may be an even better choice for studying human exposure than taking air samples

alone, as the ambient air is constantly inhaled through the nose. The air sample often represents only one part of the entire work shift. The importance of preferring the collection of nasal swab samples is supported by the observation that the difference in the microbial DNA of the nasal samples before and after the work shift was clear. In most cases, *A. fumigatus* DNA was not present in swab samples taken from the human nose before the work shift. In particular, in workers who did not work in waste management during the days before sampling, no *A. fumigatus* DNA was detected in the morning. Madsen et al. (54) have observed similar results; they measured the presence of fungi and bacteria in the noses of greenhouse workers using nasal lavage. They found that the concentration of fungi, β -glucan, and bacteria in the nasal lavage on Thursday at noon was higher than that on Monday morning. In addition, upper airway inflammation markers have increased in nasal lavage samples of composting facility workers after exposure to bioaerosols from Monday to Thursday (6). Thus, combining bioaerosol and nasal lavage microbial assays with the analysis of respiratory track inflammatory markers could improve human health risk assessment in waste treatment.

Conclusions

The results showed that workers in biodegradable waste processing are exposed to bacteria and fungi that can be harmful to health. Especially in composting facilities, endotoxin concentrations in the air often exceeded the chronic exposure limit value of 90 EU/m³. Further, *A. fumigatus* and *Campylobacter* spp. DNA levels were significantly increased, and *Streptomyces* spp. DNA quantity was elevated in nasal swabs taken after the work shift compared to the levels before the shift. Workers' exposure to microbial hazards was high enough to lead to long-term respiratory diseases. Although the concentrations of endotoxins, *A. fumigatus*, and actinobacteria/*Streptomyces* spp. in wheel loader cabins were typically lower than in waste reception and pre-treatment, the levels were often elevated compared to the control rooms or outdoors, suggesting that hygiene could be better maintained. Waste management workers should be trained to take better care of hygiene, use appropriate protective equipment and all available preventive measures to preclude exposure to bioaerosol-related harmful microbial infections, such as campylobacteriosis.

Composting is well suited for the final treatment of organic process residues, although it has the problem of high bioaerosol concentrations. The number of harmful microbes was low in bioaerosols from closed bioenergy production processes. Therefore, composting could also be developed toward more closed processes to reduce worker exposure, while using wheel loader cabins with properly maintained HEPA filters and slight air overpressure. The studied facilities were simple in structure and the transfer of compost from one site to another was

based on wheel loaders. Automation could reduce exposure to bioaerosols, although workers may face additional hygiene risks from process maintenance and repair interruptions.

The significance of qPCR assays is that they create new applications for determining exposure to pathogenic microorganisms, such as the new finding on the common occurrence of *Campylobacter* spp. in waste treatment was made in this study. Sampling of workers' nasal mucous membranes shows the actual inhalation of microorganisms that may pose a potential risk to their health. These nasal samples can also be used to evaluate how effectively respiratory protection equipment protect workers from bioaerosols.

Data availability statement

The original contributions presented in the study are included in the article, further inquiries can be directed to the corresponding author.

Ethics statement

The studies involving human participants were reviewed and approved by all procedures that involved human participants including environmental sampling were conducted in accordance with the ethical standards of the institutional or national research committee and the 1964 Declaration of Helsinki and its later amendments or comparable ethical standards. The Ethics Committee of Helsinki University Hospital approved the Study Protocol (HUS/41/13/03/00/2011). All responders provided written informed consent prior to their participation. The patients/participants provided their written informed consent to participate in this study.

Author contributions

SL and MHK designed research, sampling, and analysis methods. MK analyzed the samples and organized the database. SL wrote the first draft of the manuscript. All authors contributed to manuscript revision, read, and approved the submitted version.

Funding

This study was financially supported by the Finnish Work Environment Fund (Project 110359) and by Environment Grant 2012 from the Finnish Ekokem Group.

Acknowledgments

We would like to thank the waste management facilities, and the workers who participated in this study. We are also grateful

to medical doctors Pirjo Jokela and Kari Reijula at Finnish Institute of Occupational Health for their valuable contribution.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

5.6.6 Air Quality

Shieldhall Waste Water Treatment Works

The works are situated approximately 400 meters from the proposed development (see Figure 28). The works are the largest Waste Water Treatment Works in Scotland, serving 800,000 people (this is very large).

Conversation with Scottish Water have revealed that there are issues with five storm tanks each of which hold 1,000,000 gallons of storm water. In adverse weather, all water and raw sewage is diverted here. It then needs to be processed but the tanks are too large for odour to be contained and a lot of odour is created and released. This generates a large volume of complaints, especially in the summer. They have attempted to empty the tanks at night but are often compelled to empty them more frequently to allow for more storm water.

All normal sewage inlet channels are covered but money for more comprehensive odour control such as containment of the storm water tanks requires significant capital investment. There are plans to upscale a project injecting an enzyme into the sludge which is claimed to dramatically reduce odour. Scottish Water is looking at options for containment on the site or even relocation but there is no certainty with respect to either scope or program for this at present.

HAI-SCRIBE (Healthcare Associated Infection System for Controlling Risk In the Built Environment):
Odour does not present a direct infection risk, but may force windows and ventilation intakes closed, and this in turn may increase the risk of HAI in the healthcare facility. Clinical areas require good rates of ventilation to provide dilution of pathogens generated within the hospital and to control odours within the hospital.

Odour is unpleasant to patients and visitors. Staff are more likely to become tolerant to the smell as they are continuously exposed to it.

The improvement of air quality in healthcare settings is a constituent of modern airborne hygiene procedures. The vast majority of microbes are associated with particles and air filtration is a solution to preventing spread of infection. The air quality requirements in healthcare settings vary from department to department and, often, even from room to room. Some areas require high-efficiency filtration of airborne micro-organisms to protect patients, staff and visitors (e.g. in operation suites, ICUs, TB isolation rooms), whereas other areas require the filtration of gaseous contaminants, chemicals and odours to provide a safer and more pleasant working environment (e.g. in laboratories, autopsy rooms, dental surgeries and pharmacies). It is thus essential that only very-high-quality filters are installed in these environments.

Increasingly stringent national and European environmental legislation on air quality has resulted in the development of new filters to remove and reduce odours and chemical fumes from the workplace. These filters combine a blend of high-grade carbon and alumina/ potassium permanganate that destroys odours, corrosive gases and fumes such as ammonia, arsine, ethylene, formaldehyde, hydrogen sulphide, nitrogen dioxide and oxide and sulphur dioxide as well as contaminants normally treated with standard carbon products. These Air Processors run with near-silent fans, are odour-free in operation and create a healthy and productive environment for everyone's benefit.

An odour problem will be present at times on the proposed site of the New South Glasgow caused by the waste water treatment works at Shieldhall. Odour is best treated at source and measures to control odour at this site could well be implemented by the Scottish Government and Water Authority. If odour control at the hospital is deemed necessary, activated carbon filtration is the most suitable technology both in terms of effectiveness and cost. However, it would rely on a sealed building with a mechanical ventilation system throughout any odour treated areas.

It is proposed that mechanical ventilation systems are fitted with activated carbon filtration to remove odour from ventilation air. The buildings are to be made air tight to reduce the infiltration of untreated air.

Figure 28

5.6.7 Acoustics and Noise

External Strategy: Environmental and Inter-Building noise

General Considerations

The development of the existing hospital site should not have an avoidable adverse effect on the neighbouring noise-sensitive properties (particularly residential). Current planning policy guidance (e.g. PPG24) states that planning authorities should not place unjustifiable obstacles in the way of development. However, they may wish to consider the use of appropriate conditions, insofar as the development of the hospital may adversely affect future residential developments in the area. A normal condition is that the average predicted noise level from the newly-developed site is less than 10dB below the existing background noise levels at the nearest noise-sensitive façade. BS4142:1997 suggests that satisfying this condition will result in complaints being ‘unlikely’.

It is recommended that a full environmental noise survey of the existing site and surroundings be undertaken to establish the existing conditions in which local residents live.

Compared to a small domestic development, a large site consisting of a number of buildings renders the term ‘environmental noise’ ambiguous. The environmental noise impact on the site from adjacent existing and future roads, rail, waterways and aircraft needs careful consideration. However, the impact of one building on another building also needs to be considered, as does the effect of visitors, deliveries, blue light routes and waste collection.

BAA publications and site measurements suggest commercial aircraft noise is not likely to be an issue. However the air ambulance helicopter landing location is likely to have an impact on the site internally and local residents alike. The landing location atop the Adult Hospital renders it relatively unshielded from local residences, except for the effect of the edges of the building itself. Therefore, a barrier at the perimeter of the helipad and roof is proposed to increase the shielding. The helicopter landing pad will be vibration isolated from the roof structure such that the landing impact does not propagate unreasonably into the building.

Testing and Noise Survey

For purposes of break in, suggest $L_{Aeq,30mins}$ at selected locations around the site, deemed to be representative of the local noise environment. It is a very large site and significant variations in noise level are likely to occur, so results would have to be read in this context.

For break out noise implications, we suggest taking two 24 hour surveys $L_{A90,15mins}$ at separate locations on site boundary to establish background noise levels.

Surveys to be conducted in accordance with BS 4142:1997.

Plant Noise Around the Site

- Generators
- Air handling equipment
- Fans, pumps and compressors
- Pipe work around the site
- Specialist medical equipment
- Transformers and switch rooms
- Vacuum pumps in theatres
- Ultrasonic washers
- Kitchen equipment
- Lifts

Internal Strategy: Noise Transfer and Room Noise

Motivation for Consideration

Noise in real-life operating theatres has been recorded (e.g. Boulter 2007) to exceed 70dB L_{Aeq} (well above HTM2045 recommendations). A long session could potentially exceed the action levels of the Noise At Work regulations, and result in long-term effects on the hearing of staff. High noise levels (e.g. from equipment) is reported to be one of the most likely reasons for complaint by hospital staff.

Studies have also suggested that a good acoustic environment could reduce the likelihood of rehospitalisation (particularly of heart patients).
Communication (English as 2nd language, hard-of-hearing, new/complex information to process)

Privacy issues (maternity, consultation etc) are critically important. Protection of personal health information is implicit in the Human Rights Act, suggesting possible legal recourse, although not many precedents yet.

The possibility of Music Therapy?

Establishing Design Parameters

Suitable upper limits for indoor ambient noise levels from HTM2045-2.

Prediction of source noise levels (external and internal) gives structural sound insulation performance parameters. The care taken over the structure needs to be reflected in the details of doors, windows and structural junctions as well as the constructions generally. The requirement for heavy acoustic doors will be balanced with the ability of users (e.g. patients/children) to use them. Services voids can act as useful buffers between floors, in which sound can be absorbed.

High reverberation time adversely affects internal noise levels and speech intelligibility. Reverberation times can be lowered by including acoustic absorption in the spaces, but it is important to establish any areas of concern regarding cleaning of acoustic absorption, as it is usually inherently porous. Many products are cleanable and designed for use in the healthcare industry. Required reverberation times will be taken from BS8233 and HTM2045-2.

Suggested Design Parameters from HTM 2045-2

AREA	Max unoccupied ambient noise (NR)
Lecture theatre	35
Operating theatre	35
Private office meeting and consultation room	35
Multi bed ward, waiting room	40
General office	40
Staff room, recreation room, cafeteria	45
Corridor, laboratory	50
washroom, toilet, kitchen	50

with mechanical services achieving levels at least 5dB below those specified above.

Location	Recommended Privacy Factor
Maternity, nursery, A&E	80+
Operating theatre, single bed ward, multi-bed ward	80
private office, meeting and consultation room, lecture theatre	
Laboratory, staff room, general office	75
Waiting room, corridor, wash room, toilet, kitchen, recreation room, cafeteria	70

Reverberation time in critical spaces to be controlled to 0.6-1.0 seconds depending on room volume and activity.

Impact sound between occupied areas $L'_{nT,w}$ not to exceed 60dB on average.

Vibration criteria to be confirmed in relation to BS6472.

See the glossary for an explanation of the terms.

Significant Noise Sources

- A&E and outpatients
- Psychiatric
- Maternity and nurseries
- Boilerhouse/laundry/workshop/goods
- Any areas of construction/demolition around the site – to be managed by Contractor
- Waste disposal
- Drawers closing, footsteps, ring binders, trolleys passing over discontinuities in the floor

- Medical equipment
- Raised vocal levels due to ageing population
- Cardio-training treadmills – impact noise to below

Significant Noise- or Vibration-Sensitive Areas

- Children's
- Maternity
- MRI
- Wards generally for sleeping and recuperating
- Library

Design Considerations for Internal Strategy

Sensitive areas generally will be physically separated as far as possible from noise/vibration producing areas. Either with a physical gap, or a buffer zone e.g. corridor, other circulation area or store.

Noise transfer via corridors will be minimised with absorption and lobby doors. Noise within corridors will be reduced through use of acoustic absorption.

Noise transfer between rooms for privacy means careful planning of doors and windows as they are usually weak links.

Acoustic detailing on joints and penetrations, and cross-talk in ducts will be assessed and controlled.

Impact and airborne noise from kitchen facilities – locate kitchen on level below wards.

Advisable to centralise dishwashing and sterilization facilities for large areas and provide attenuation between them and the wards they serve.

Vibration-isolation of MRI and other super-sensitive equipment e.g. microscopes/labs to manufacturers' specifications.

Audiology (especially vestibular function test facilities) in particular will need to be isolated with care.

Testing: Internal impact and airborne noise levels and transfer measurement tests, plant noise, internal reverberation time, public address intelligibility.

Acoustics in Relation to Environmental Design

Exposing areas of structure with high admittance, as thermal mass, helps to reduce the requirement for mechanical cooling by damping out the peak temperature fluctuations in summer. To work properly the thermal mass needs both line-of-sight into the space for radiant cooling effect, and convective access to the air in the space, for convective cooling effect. There is a potential conflict with acoustic absorption which has poor thermal mass properties and is normally mounted at high level, obscuring the thermally-massive substructure. This can be mitigated in a number of ways, including: mounting the absorption at the perimeter of the ceiling; or high level on the walls; or as baffles suspended from the ceiling to allow a free air path around them; or integrating the absorption with suspended services elements such as light fittings.

The choice of predominantly mechanical ventilation is advantageous acoustically, as it affords better control over openings between inside and outside. For instance sound propagation duct routes can be attenuated with attenuators or duct lining.

Design for good daylight can result in tall spaces (with high windows) to enable daylight to penetrate further into the floor plan. This has the adverse acoustic consequence of increasing the reverberation time, as the volume of the space increases. The advantages of better daylight need to be traded off against the potential requirement for larger areas of acoustic absorption.

GLOSSARY OF ACOUSTIC TERMS

A-WEIGHTED SOUND PRESSURE LEVEL, L_A (DBA)

SPL values are weighted in a way that approximates the frequency response of the human ear and allows sound levels to be expressed as a single figure value.

EQUIVALENT CONTINUOUS A-WEIGHTED SPL, $L_{Aeq,T}$ (DBA)

Energy average of the A-weighted sound pressure level over a time period, T. The level of a notional continuous sound that would deliver the same A-weighted sound energy as the actual fluctuating sound over the course of the defined time period, T.

DAILY PERSONAL NOISE EXPOSURE LEVEL, L_{DPNE} (DB(A))

The measure of sound 'dose' used by the Noise at Work Regulations. The value is the sound energy equivalent a constant value for 8 hours. E.g. 90dB for 8 hours has the same value as 93dB for 4 hours.

SOUND LEVEL DIFFERENCE, D (DB)

The difference in sound pressure level between rooms on either side of a partition. D varies with sound frequency.
 $D = L_{P1} - L_{P2}$

WEIGHTED STANDARDIZED LEVEL DIFFERENCE, $D_{NT,W}$ (DB)

A value calculated from the frequency dependent values of the standardized level difference, D_{nT} , according to a weighting method described in EN ISO 717-1. This allows the sound level difference of an element to be expressed in terms of a single value.

WEIGHTED SOUND REDUCTION INDEX, R_w (DECIBELS, DB)

A value calculated from the frequency dependent values of the sound reduction index according to a weighting method described in EN ISO 717-1. This allows the sound reduction of an element to be expressed in terms of a single value.

PRIVACY FACTOR, PF (DB)

The sum of the apparent weighted sound reduction index R'_w and the internal ambient noise criterion (usually NR). PF>80 is 'inaudible'; PF<70 is 'clearly audible and intelligible'

IMPACT SOUND PRESSURE LEVEL, L_i (DB)

Average sound pressure level in a specific frequency band in a room below a floor, when it is excited by a standard tapping machine as defined in BS EN ISO 140-6.

WEIGHTED STANDARDIZED IMPACT SPL, $L'_{nT,W}$ (DB)

A single value calculated from the frequency dependent values of the standardized impact sound pressure level, L'_{nT} , according to a weighting method described in EN ISO 717-2.

ABSORPTION COEFFICIENT, α

The fraction of the incident sound energy that is absorbed on contact with a surface expressed as a fraction between 0 and 1. The higher the value of the absorption coefficient, the more sound that is absorbed by the surface.

REVERBERATION TIME, RT (SECONDS)

The reverberation time of a space is a measure of the rate at which sound decays. It is the time taken for the reverberant sound energy to decay to one millionth of its original intensity (corresponding to a 60dB reduction in the SPL).

5.6.8 Thermal Comfort

General Considerations

High levels of comfort are required for all users; in particular staff and patients. This will have an effect as to how the overall building and the health care provided is perceived, affecting staff performance and patient well being.

Many clinical areas require close control of the room environmental conditions to make the spaces functional. This tends to lead to spaces with air conditioning and/or comfort cooling. Temperature, humidity and air distribution are all carefully controlled and can provide good levels of thermal comfort.

For other areas broader environmental conditions are acceptable and there is the possibility of natural ventilation and mechanical ventilation with or without comfort cooling. To achieve good thermal comfort good zoning, controls, operation and maintenance are essential.

Natural ventilation can provide good thermal comfort throughout the year. For a naturally ventilated space people tend to be more tolerant of high summertime temperatures and their comfort generally. Contact with outside and higher summer air movement improves comfort. The design of ventilation openings is critical. Good solar heat control and exposed thermal mass are pre requisites for natural ventilation to provide satisfactory thermal conditions. Openable windows are often used as part of the natural ventilation strategy, and it is necessary to ensure that other, often contradictory requirements such as restricting openings for safety reasons, are met.

For mechanically ventilated spaces there is less contact with outside and usually little or no direct user control of the summer environment. Often the comfort expectation is raised. The heat gain from fans and duct gain raises the temperature of ventilation air above ambient. In our view for mechanical ventilation systems to internal areas or areas without openable windows peak mechanical comfort cooling is required to provide adequate thermal. Missing a word at the end of the sentence?

HTM(03) places a space temperature limit of >28deg for less than 50 hours in any year as a measure of acceptable thermal comfort.

This type of measure does not recognise the adaptive nature of comfort in relation to the external climate and temperature. In our view, a better measure is of the internal temperature in relation to external air temperature. For naturally ventilated spaces the building should be designed with good solar protection, adequate thermal mass and adequate well designed openings for ventilation such that the mean internal temperature is as close to the mean external temperature as is possible and that the internal peak temperature does not exceed the peak external temperature. If this can be achieved the building will be perceived to have good levels of thermal comfort.

For air conditioned and comfort cooled spaces seasonally adjusted control temperatures should be used. The building should be designed as if it were to be naturally ventilated or so that for perimeter rooms at least it is possible at some future time to successfully naturally ventilate the space Good solar protection and adequate thermal mass reduce the cooling load substantially. The mean summer internal temperature should be at the mean external temperature and the internal peak temperature two or three degrees below the peak external temperature is required for the reasons described above (higher expectation, poor user control) for the building to be perceived to have good levels of thermal comfort.

The summer weather is variable in that some years and hotter than others. During hot years this the HTM(03) limit are difficult and expensive to achieve as they are unrelated to external air temperature. Climate change will make the achievement of these criteria more difficult over the life of the building particularly for natural ventilation solutions. For PFI contractors the HTM(03) limit present an unacceptable technical and commercial risk which leads to a mechanical ventilation solution with comfort cooling in preference to natural ventilation solutions.

5.6.9 Operability

General Considerations

Mechanical and electrical systems shall be automatically controlled. Controls shall be robust, battery backed and distributed as far as is possible so that each system or plant has it's own integral or local controls for resilience.

For clinical areas full system controls and control value presentation will be provided in a secure staff location.

For staff and patient areas, user controls are to be provided to allow trimming of the environmental conditions within the staff/patient space. These include:

- temperature adjustment + or _ 3 about set point, return to set point next reset or start point
- ventilation rate adjustment low, high, boost, return to set point next reset or start point
- light switching and dimming for single room/bed head fittings
- window shading and day light control

For patients control will be available from the bed position.

Room/space conditions will be centrally logged on a twenty minute time base to a system database. Real time display, graphing against time, database retrieval, and archiving software will be provided.

A building energy metering, monitoring, reporting and targeting SCADA data collection and management software will be provided for energy management. Metering will be divided according to zone , building function and service, eg lighting and small power will be separately metered; large equipment loads will be separately metered, zone by zone heating and cooling will be metered. This is to allow energy targeting management and monitoring to be carried out on an ongoing continuous basis.

Building Record/As Installed documentation will be centrally help in a digital format arranged, indexed and maintained to be available through a common access portal over the hospital IT infrastructure using standard software.

Operating Plant monitoring, condition management and maintenance software will look at plant and system operation, condition, operating hours and maintenance intervals to determine and program system maintenance requirements. Maintenance shall be automatically planned and logged to form system and individual items, maintenance records include life cycle costs. Maintenance tasks and records shall be communicated with WiFi communication to operator smart PDAs. O&M information shall be linked to Record System & Asset Information so together they provide an integrated and up to date record of the of the system at any time.

Boiler and chiller plant efficiency and heat output will be continuously measured and logged together with key operating parameters to allow optimisation of operation and efficiency.

Energy and space/room efficiency, availability and time within control parameters are to be collated and presented manually as a system report.

All control functions management systems and system data shall be interconnected on an Ethernet backbone and data servers so that it is available across the hospital IP backbone to PC users with correct permissions. Management software will control access, reading and editing rights in addition to recording usage.

Section 6 – Design Proposals 4 – Compliance, Build Quality and Engineering

6.1 Fire Strategy

The complexity and size of the new build is such that a detailed fire strategy will have to be developed. The TA Team have advised the Board to engage the services of a specialist Fire Consultant to comment on the proposals and work with the Team to help develop the design. This will have to be considered during the next stage.

The Stage 1 PSC has made certain assumptions in respect of both means of escape and fire fighting access but these have not been developed or tested and need further development.

As described above the adult ward arrangement adopts the dual corridor solution to provide alternative horizontal escape from the peninsular ward. The ward is then subdivided lengthwise into two long compartments with fire doors across the links. It is envisaged that these doors would be help open during normal operation with the releases linked to the fire alarm. The end stair is accessible from both compartments independently. The arrangement effectively allows continuous horizontal alternative evacuation to an adjacent compartment and from there into a further compartment and so on. The provision of corridor in each compartment would be sufficient to allow the beds from an adjacent compartment to be accommodated.

In the case of the Children's wards alternative routes are provided with wards again divided into compartments and sub-compartments.

Fire brigade access is possible to all four ground floor faces of the building. Fire fighting shafts within the building will be required. It has not been possible to determine whether dual-use lifts would be acceptable or if dedicated Fire Fighting lifts will be required. This will be subject to agreement with the approval body.

The adult ward plan assumes the end stairs are primarily for escape and fire brigade access. A fire fighting lift is indicated at each of these four locations. Given the distance rule from the fire fighting shaft to any point on an upper storey, it is assumed that one of the shafts in the central core will also have to double for fire fighting access.

The size and scale of the development will also require an engineered approach to resolve access to the base of the fire fighting shafts. It has been Avanti's experience on other projects that the distance from the ground floor entry point, to the vertical shaft can be extended subject to the route being fully protected using pressurisation and other enhanced protection. These issues will require further consideration in the next stage. For other M&E installations associated with Fire Strategy see below.

6.2 Structural Strategy

6.2.1 Introduction

In order to develop and provide all necessary supporting information to establish the Outline Business Case (OBC) for the new hospital facility, an overall civil and structural engineering strategy is required to outline the requirements for the detailed design and construction of the new hospital and associated developments for the site. This Design Substantiation Report (DSR) presents and discusses the considered engineering strategies based on the constraints and restrictions of the existing conditions at the site as far as they are known and the information available to date. The information referred to in the following report also provides relevant input of the design aspects for the public sector comparator (PSC).

6.2.2 Geotechnical, Geochemical & Environmental Considerations

Sinclair Knight Merz has reviewed geotechnical information from a number of past site investigations undertaken over the last 30 years, with the intention to assess and summarise any potential geotechnical issues, ground conditions and foundation options that will be relevant to future development proposals for the facility, and in particular the proposal to build a new high rise structure with basements and subway access. The positioning and extent of previous investigations is summarised on drawing EK02355-S-001-P1.

6.2.3 Review of Available Ground Investigation Reports

The site is situated on an alluvial floodplain approximately 500m south of the River Clyde in Glasgow. Of the nine previous ground investigations carried out at the site, approximately a third of the site's area was covered to depths proving the location of bedrock. The ground at the site consists of made ground that is underlain by alluvium, which is in turn underlain by glacial till and Carboniferous Coal Measures bedrock.

The made ground consists of a mixture of cinders, ash, sands and gravels, and brick, and ranges in thickness between 0.3m and 1.75m. The alluvium generally consist of soft to very soft clays and loose to medium dense silts and silty sands, of

approximately 20m total thickness, but locally thinning to approximately 16m. The alluvium was generally found to be of high to medium compressibility. In one site investigation report it was noted that differential settlements had adversely affected existing buildings at the site.

The glacial till is described as stiff to very stiff and varies in thickness from less than a metre to approximately 15m, with an "average" thickness of approximately 6m. The upper horizon is often weathered but strength increases with depth. Compressibility of the glacial till was found to be low to very low. Bedrock was found at various depths ranging between 15.5mbgl (metres below ground level) to 25.5mbgl. Bedrock was found to consist of inter-bedded layers of sandstone, siltstone, and mudstone with occasional thin seams of coal. A thin layer of igneous rock was found at one location in association with evidence of a fault zone or discontinuity. The strength of bedrock ranged between very weak (coal), moderately weak (mudstones) to moderately strong and strong (siltstones and sandstones).

From desk-top studies undertaken as part of the previous site investigations, no evidence of shallow mining was recorded in the ground investigations and the Coal Authority confirmed that they have no knowledge of mining activities previously taking place beneath the site. However, two reports confirmed that a mine shaft was marked on historical maps within 70m of the investigated areas, but suggested that the position is not related to the existing hospital site. There is also indication of a trial mine shaft more centrally within the proposed site, but it appears only on early plans and is not referred to elsewhere or known to the Southern General Hospital's Estates Team. Further investigation into the location or existence of historical mine shafts is recommended to be carried out.

Groundwater and perched groundwater exists at the site at depths ranging between approximately 1.0 mbgl to 4.0 mbgl. However, where the drift deposits are relatively impervious, groundwater was not encountered until near-bedrock depths. Water strikes at these depths generally produced sub-artesian groundwater rises of between 6m and 10m.

6.2.4 Geotechnical Considerations

All the previous reports have concluded that the soft alluvium underlying the site has the potential to induce excessive settlements if structures were founded on spread foundations. A range of bearing capacities between 60 to 100kN/m², depending on drift geology, has been suggested. To reduce settlement some reports have recommended the use of large sized spread foundations and raft foundations for low rise buildings, but it has also been noted that settlements in excess of 25mm would still occur. All the reports concluded that structures with higher loadings, and settlement sensitive structures, should be either founded in the glacial till or socketed within bedrock by using an appropriate system of piled foundations.

The maximum bearing capacity of the bedrock was tentatively specified as 1.0MN/m² in one report. It is noted that the 1998 Arup report recommended a maximum safe working load of 480kN for 600mm diameter piles founding in 6m of glacial till and a maximum safe working load of 500kN for 220mm diameter mini-piles socketed a minimum of 3m into bedrock.

The majority of the reports recommended the use of bored cast in-situ piles such as the Continuous Flight Auger (CFA) method of emplacement. One report concluded that down-drag of piles would need to be taken into account in the pile design. Vibro-replacement ground treatment of the weak alluvial deposits was discounted due to the presence of cohesive deposits.

For deep excavations, significant basements, or below ground corridors it was generally concluded by most site investigations, that groundwater would likely be an issue but that it could be feasibly controlled by sump pumping and temporary sheet piles.

On the basis of the available information from previous site investigations, it is considered that the whole hospital site is underlain by potentially highly compressible material that would adversely affect structures if founded above or within these compressible deposits. Therefore it is considered that any structures more than two storeys high will require to be founded at either very stiff glacial till or taken down to bedrock level.

The excessive depths to bedrock and the low shear strength of cohesive deposits to significant depth is likely to require building loads to be supported on piled foundations taken down and socketed into the underlying solid deposits. This will require pile lengths in the order of 20m to 25m with adequate socket lengths to provide the required carrying capacity (typically about 3-5m but dependent upon the actual loading).

For the ITN stage and as part of the documentation, a detailed ground investigation will require to be undertaken by GG&CHB Trust to provide a general overview study of the entire site to establish the nature of the ground strata. With respect to the footprint of the proposed building, the location of the offsite mine shaft and the centrally located mine shaft as recorded in historical maps should also be investigated as part of this pre-ITN investigation.

It is expected that further detailed site investigation to suit the outline of the proposed development will be carried out by the preferred bidder prior to financial close.

The site infrastructure will be highly dependent upon any change in topography during earthworks cut-and-fill operations. Should there be any soil retention requirements then the design of such retaining walls and foundations will need great care to guard against sliding in such low strength founding materials.

Given the existing ground conditions, it may be the case that drainage runs need to be laid to steeper gradients than design minima and with regular rocker pipes to enable continued operation should the softer clays settle under the imposed weight of the site infrastructure. This effect will become more prominent if significant areas of the site are raised in level, even by a nominal amount (such as required to provide a piling mat, which in this situation is likely to be thick).

Excavations may be prone to groundwater ingress so consideration to the use of tightly interlocking sheet piles around excavations may be required for any deep excavations, with appropriate allowance for pumping from the base of such excavations.

Where basements are to be formed with service ducts the ground loading will be reduced, which may have a consequential reduction in the heave of the existing cohesive strata. The main issues will be that of water tightness both permanently and during construction. Basements will require to be formed from in-situ reinforced concrete or similar construction with a suitable water-proofing system to retain the external water table under adverse conditions.

6.2.5 Geo-chemical and Environmental Considerations

Minimal ground contamination was encountered in any of the previous site investigations. However, given the existing and previous uses of the site there may well be areas that require any undetected contamination to be addressed. The raised pH levels were established in some areas of the site, but are not such as to require special precautions in normal concrete foundation works, however this needs to be investigated further.

Historically, site investigations were commissioned on a number of occasions and SKM-AH has produced a drawing collating the various site investigations undertaken. This drawing is supported by the interpretative reports produced as part of each investigation. Testing for contaminants was undertaken as part of these investigations and revealed little in the way of contamination at those locations where testing was undertaken. However the locations available for testing were limited by existing services, buildings and other operational areas which necessarily means that large areas of the site have not been tested for contamination. It should also be noted that testing criteria for contamination has become far more stringent over recent years and for that reason the apparent lack of previously identified contamination material should not be assumed to be reflective when benchmarked against current criteria for evaluation.

A number of buildings have been demolished as the site has been developed over the last 100 years. The extent to which the sites were cleared before reconstruction with regard to infilled basements, foundations and the like, is unclear and these locations remain potential sources of contamination and may pollute normal groundwater where this comes into contact with the material.

Likely residual contaminants may include hydro-carbons, asbestos, medical waste or related materials and may be diffuse or in pockets around the site.

We understand that it is GG&CHB's intention to hand the site over to the preferred bidder as a notionally 'clean' site for all development work. It is proposed to achieve this through a series of enabling and remediation works to clear the site and also to relocate active services and discontinue services that are currently on the proposed building footprint. However it should be noted that should there be significant contamination found on-site, the majority of which will be below ground and cannot be readily removed/remediated until the sub-structure works are underway. Notwithstanding the above, a comprehensive detailed site investigation with appropriate sampling and geo-chemical testing of the entire site will be required to identify the likely extent of remediation or removal.

6.2.6 Site Conditions on the Existing Hospital

Ground Engineering Characteristics

The engineering characteristics of the superficial deposits to the site are considered to be such as to economically mitigate against their use as founding layers for anything other than low-rise buildings of two storeys or less.

6.2.7 Ground Conditions Risk Summary

The risk register in support of the OBC should include provisions for the following civil engineering and geotechnical risks:

- Poor ground conditions to an average of 20m depth;

- Moderate to severe risk of ground contamination from a variety of sources given the length of time the site has been used as a hospital;
- Presence of groundwater within excavations;

- Contamination in areas of made ground including potential asbestos, hydrocarbons and heavy metals.
- The depth to sound rock-head may be greater than that currently assumed on the available information, and as such the risk register should include an allowance for this.

6.2.8 Roads Infrastructure for Hospital Site

The development of the highway infrastructure is likely to be required under conditions as part of the Planning approval and the Traffic Impact Assessment/Green Travel Plan for the scheme within the context of the wider transportation issues in Glasgow and environs. The extent of new junctions, new site accesses and all road improvement works will need to be progressed as the proposal for the existing site is developed and as planning comments are received.

At present the scheme maintains current accesses from Govan Road and Hardgate Road and details a new blue-light route from the A739 at the southern end of the site. These road junctions will require Highway Authority and Local Authority approval and should meet all statutory requirements.

Further advice and consultation has been provided by Ironside Farrar, WSP and Keppie Planning to gain Outline Planning approval.

Internal site access roads will comply with the appropriate highway standards, supporting the required design traffic flows.

6.2.9 New Buildings

The following text outlines the assumed engineering development strategies for the new hospital buildings and multi story car parks which are to be used in the outline business case and preferred option for the public sector comparator (PSC).

The multi-storey car park options (at two locations), are to meet the anticipated parking demand for the site given its location in relation to the city of Glasgow and notwithstanding the proposals to provide multi-mode transportation options for patients, staff and other site users.

6.2.10 Standards and Regulations

The new development including both hospital buildings and multi story car parks will need to be designed and constructed in accordance with the relevant Design Standards, Building Regulations, Planning Conditions, statutory and local authority standards and to the CDM2007 Regulations.

6.2.11 External Works

The generally flat/gently sloping nature of the site will generate minimal areas of cut and fill across the building footprint. However, construction levels will require to be established at the necessary design levels including basement areas, service and access ramps and to ensure functional tie-ins for connections to existing buildings that are to be retained as part of the new facility. All proposed water features, retention systems and landscaped areas will also require further areas of lower-lying ground to be excavated and profiled.

Excavated material can be retained on site and used for ground profiling / landscaping works provided that any identified contaminated material is either re-mediated or removed. Retained material will also have to be appropriately assessed in terms of engineering properties for the intended end use on site.

It is noted that although much of the site is hard-standing, there may be an opportunity to retain some topsoil stripped from existing landscaped areas within the site. In such circumstances, the topsoil should be assessed and if suitable, stockpiled for reuse.

With regard to Tree protection Orders (TPOs), it is noted that there are some protected trees within the site. These will have to be incorporated into the eventual landscaping strategy and adequately protected to the requirements of a suitable arboriculturalist's requirements during construction works.

Tie-ins for connections to the existing road network, hard-standing areas and other features will require to be fully integrated with the design levels established across the site.

6.2.12 Proposed Hospital Building Foundations

The Master Plan for the new hospital facility consists of a series of ward towers to a maximum of 13 storeys plus the ground floor, podium and roof structure. The foundations for the hospital building are likely to take the form of reinforced concrete pile foundations socketed to a minimum of 3 metres into the sandstone rock head at a depth of 20-25 metres below ground level. Preliminary assessments indicate that foundations bearing in the glacial till at shallower depths would not be suitable, due to the magnitude of the load expected and consequent short and long-term settlements. Settlement for the piled solution should be designed within acceptable limits. It should also be noted that there is likely to be some degree of underground obstructions encountered when placing these piles which are expected to be existing concrete foundations and other historic features.

If bedrock is deeper than that currently assumed from available information, then deeper piles with longer rock sockets may be required beneath the foundations to reach sound bearing bedrock.

Across the footprint of the proposed structure the existing ground is fairly level. Consequently all basement areas will be consistent across the full footprint of the site as required by operational planning criteria. Basements and tunnels will require water-tight retaining walls and to be founded either to bedrock or with a suitable arrangement of raft foundations to prevent differential settlement. These are likely to be formed of in-situ reinforced concrete construction resisting lateral earth, water and imposed loading pressures. Adequate tanking must be provided to below ground structures where permanent or localised water table levels dictate, under the most adverse conditions anticipated.

6.2.13 Proposed Hospital Building Superstructure

The superstructure of the building is the structural frame that will be responsible for the transfer of gravity, imposed and lateral loads to the ground in a manner that ensures vibration (a key issue for hospitals) and noise transfer are kept to minimum levels. Dynamic loads from the helicopter landing pad proposed on the roof of the building will also have to be taken into consideration with regard to vibration assessment.

With regard to services integration it is recognised that hospital structures need to take cognisance of current service requirements as well as some degree of flexibility for future fit outs and refurbishment during the buildings life span. Services routes will run through the hospital on both horizontal and vertical axes and the structural design of the frame should be sensitive to this requirement. Ease of access and routing of services can be achieved for example by the adoption of flat soffit slab methods of construction or open web construction including a range of proprietary systems.

A nominal structural planning grid of 7.8m x 7.8m (maximum) has been developed by the architect for this Design Substantiation Report in support of the OBC and for the PSC. A column grid of this spacing is likely to be achievable using a number of different construction materials and structural systems. This includes structural steel, in-situ concrete and pre-cast concrete solutions. Attention should be paid to the ability of the final design solution adopted such as to ensure that structural stiffness can be achieved and that the structural footprint is sufficiently flexible to allow the hospital to achieve its necessary space planning targets.

The upper floors of the hospital building cruciform tower and parts of the podium have for the purposes of the PSC, have been nominally assumed to be either a slimfloor steel solution or an in-situ reinforced concrete (RC) flat slabs without down-stands. SKM-AH Drawings NE02355-S-201 & NE02355-S-202 show indicatively how the structural make up might be achieved for the hospital building for each respective type of construction. The drawings show typical details and plans for a ward and operating theatre that will allow flexibility with horizontal services distribution and will reduce overall floor construction depths to a reasonable minimum. Structural columns are centred on the grid as referenced above and such as to reflect the geometry of the building and how the structure will transfer the loads to the foundation systems. It should be noted that in the case of the flat slab construction a slightly deeper than normal slab has been assumed at this stage in order to assist with dynamic loading issues. Detailed design assessment may be able to reduce this depth from 350mm to 300mm but this would require careful consideration of bracing locations and circulation shafts.

Although we would not rule out the possibility of using cellform construction and downstand beams we would note that a lighter form of construction than those discussed above would require extreme care in relation to dynamic response and sensitivity issues associated with vibration, particularly on tall buildings.

Ground or basement floors are envisaged as suspended slabs supported from a grillage of beams on the pile caps on socketed piles in sound bedrock.

Lateral stability of the structure could be achieved through a combination of rigid moment frames, bracing bays or the use of reinforced concrete stair and lift cores.

6.2.14 Proposed Hospital Building Fire Resistance

The structure should be designed to achieve the necessary levels of durability and appropriate periods of fire resistance in accordance with all applicable standards, current codes and best practice guidelines. This should take due consideration of the nature of the facility both in terms of the wide range of occupant types and the different physical aspects of the buildings i.e. the tower, podium and Children's facilities.

6.2.15 Proposed Hospital Building Construction Methodology

The new facility will be constructed within an operational hospital and due cognizance of this should be taken in the selection of plant, materials and the construction methodologies adopted. In addition, the new facility will be completed in phases over several years with staggered decants for different patient groups and staff. Due cognizance should be taken of this in the phasing of the construction works, access arrangements, availability of facilities and services and with suitable consideration of the needs of building occupants adjacent to ongoing construction or fit-out activities. Programmed activities should assess and manage all implications of staged completion to mitigate and minimize the affects on all stakeholders at the existing hospital which remains functional until full and complete transfer of facilities.

Both flat slab construction and slimfloor design are widely recognised forms of construction and have been used successfully for buildings of this nature in the UK. The slimfloor solution may have slight benefits in terms of speed of frame construction, but this is often counter balanced by traditional flat slab concrete frame construction that allows follow on trades to work on the lower floors whilst the structure is still being erected.

Tower cranes will be required for the construction of the building and space exists for these to be sited within the constraints of the site. No overhead restrictions are obvious, other than in the use of the existing operational helipad, based upon visual inspection of the site.

Care should be taken during excavation, in particular with reference to localised groundwater inflows, buried services and the temporary stability of excavations.

6.2.16 Proposed Multi-Storey Car Park Foundations

As with the hospital building the foundations for the MSCP building are likely to take the form of a grillage of beams on pile caps on piles socketed into sound bedrock at 20-25metres beneath the site. Findings from the existing site investigation interpretative reports indicate that foundations bearing in the glacial till at shallower depths would not be suitable due to the magnitude of the load expected and consequential long-term settlement. Settlement for the piled solutions should be within acceptable limits. It should be noted that there is also likely to be some degree of underground obstructions encountered when placing these piles which we would expect to be existing concrete foundations or other historic features.

6.2.17 Proposed Multi-Storey Car Park Superstructure

The proposed multi-storey car park structure (MSCP), is likely to consist of a maximum of 4 storeys plus the ground floor level. The superstructure of the building is the structural frame that will be responsible for the transfer of gravity, imposed and lateral loads to the ground.

A structural planning grid of 7.2 x 17.4m (maximum) has been adopted for the MSCP in support of the OBC and PSC. This grid allows 3 standard parking bays between columns and floor plates that clear span the length of 2 parking bays and the main vehicle corridor and the provision of a suitable width, segregated pedestrian walkway.

The construction of multistorey car park structures lends itself to a variety of precast and insitu forms of construction including, precast concrete, insitu concrete, long span cell form beams, etc. The merits of one form over another is expected to be a matter for detailed design resolution, but for the purposes of the PSC has been suggested as a pre-cast concrete floor supported by a structural steel frame.

Ground floors are envisaged as non suspended ground bearing structures of flexible material such as tarmacadam or asphalt. If basement areas are required then the basement floor construction would require to be reinforced concrete suspended slabs on a grillage of beams on pile caps on piles socketed in to sound bedrock.

Lateral stability of the structure could be achieved through rigid moment frames or by the adoption of reinforced concrete stair and lift cores to provide vertical cantilevers resisting the horizontal loadings to the structure or through appropriate vertical bracing.

Movement joints will need to be incorporated in accordance with good practice to effectively accommodate all thermal, differential and moisture movement. Joints should be located such as to avoid critical structural areas of the building as necessary.

6.2.18 Proposed Multi-Storey Car Park Construction Methodology

Construction will be undertaken within an operational hospital and due cognisance should be taken of this in the selection of plant and in the construction methodologies adopted.

The design proposed for the MSCP is typical of buildings currently under construction in the UK. Standard construction methods and techniques can be combined with modern technological developments within the industry to assist in delivering the proposed design solution. The site and adjacent areas potentially provides sufficient areas of storage and, other than the normal applicable statutory obligations, the site has sufficient access for construction deliveries.

Tower cranes will be required for the construction of the building and space exists for these to be sited within the constraints of the site. Other than helicopter access to and from the existing helipad, no overhead restrictions are obvious upon visual inspection of the site.

Care should be taken during excavation, in particular with reference to localised groundwater inflows, buried services and the temporary stability of excavations.

The design should address the exposure of the structure and discharge of surface water from the MSCP in order that future maintenance is minimised.

6.3 Services Strategy

SITE SERVICES & INTERGRATION WITH EXISTING SERVICES STRATERGY

6.3.1 Water

Read in conjunction with drawings 3757/S10P/000-010, inserted in appendices A. These relay the approximate routes of the existing site infrastructure

Mains water is required for domestic water supply and fire fighting.

The existing site water infrastructure is supplied from 5 no metered, mains connections; 2 from the Govan road; 2 from the A739 bypass road and one from Hardgate road. With the exception of the Hardgate road supply the current site infrastructure does allow for these to be cross connected and thus act as alternative supplies. Existing buried distribution pipework is likely to be of a material and age that now requires replacement. The current infrastructure cross connects fire mains with potable water mains.

Prior to the commencement of the PFI construction phase the buildings within the site boundary are to be demolished and existing potable water connections made redundant or removed.

It is currently proposed that the new PFI hospital buildings will be supplied from dual supplies, one from Govan road and the second from Hardgate road. This is subject to confirmation from Scottish Water (see below). These will need to be installed prior to the completion of the Children’s hospital and sized to supply the Children’s and Adult’s hospitals simultaneously.

Following the completion of the PFI construction phase and the occupation of the new adult hospital, the redundant buildings on the site are to be demolished, with their related potable water supplies made redundant or removed.

Scottish Water have been appointed to complete a detailed survey of the existing infrastructure, including a leakage analysis and some flow and pressure tests, these are currently underway. Following this they are to complete a hydraulic model for the existing site and then adapt this to model the proposed site. The conclusion of their works will establish the off site infrastructure implications. This Scottish Water work is programmed to be complete by the end of July 2007.

The site fire mains will be identified as part of the Scottish Water survey works (see above). The new development is proposed to have new dedicated fire mains connections serving the related supplies/outlets. The existing infrastructure is to be rationalised as part of the pre and post PFI construction works, so as to ensure the remainder of the site is adequately served.

6.3.2 Power

Read in conjunction with drawings 3757/HVP/000-010, inserted in appendices A. These relay the approximate cable routes forming the existing site infrastructure

The existing site is fed from two supplies routed from the A739 road into the Pharmacy HV switch room, from where HV cables are routed around the site to more local HV/LV sub stations. A number of the existing supplies are radial feeds.

The existing hospital MV (11kV) electrical services generally emanate from the existing primary MV switchgear. The existing incoming supply capacity is understood to be about 3MVA and currently operates at about 2.6MVA. The local electrcity supply distribution network operator (DNO) – Core Utilities, (Scottish Power), have indicated that this could be increased to a maximum of 5MVA, and that the existing secondary supply could be upgraded to a dedicated, ‘firm’ supply rated at 5MVA.

Prior to the construction phase of the PFI project, the HV switch room is to be relocated into Pharmacy and a new maternity sub station is to be installed. The infrastructure is to be modified to suit the new HV switch location and the Surgical sub station is to be reefed from the HV circuit that also serves the new maternity sub station. These enabling works allow the buildings on the PFI site to be demolished and disconnected without any disruption to the remaining buildings. The two HV supplies that currently cross the site to the Surgical sub station become redundant and can be removed.

The new hospital buildings are of greater area and serving a greater number of patients with greater intensity/scope of service. The site requirement for power will be substantially increased and the electrical supply capacity and robustness will need to be increased.

We are currently working with Scottish Power to determine the options to increase the site electrical supply. Substantial offsite works will be required and is likely to require an on site Medium Voltage 33kV substation to be established off or on the site. The Scottish Power requirements/proposal is likely to affect the incoming HV arrangement and switch room described above.

Incoming MV Electrical Supply

A reminder of the electrical loads for the development:

- Total site load after site diversity = 15 MVA with redevelopment and “growth factor”
- RHSC = 2.5 MVA
- AAH = 6.5 MVA
- Total PFI load after building diversity with expansion and “growth factor” = 11MVA

The combined Assumed Maximum Demand for the new hospitals as initially built and currently briefed is estimated to be approximately 8.7MVA. Assuming expansion as planned for and a growth factor of approximately 20% in line with HTM-06-01, the Assumed Maximum Demand will be taken to be 11MVA. All 11kV switchgear, cable distribution and standby generation capacity should be sized on this basis.

Dual incomers from DNO rated at 15MVA at 33kV :

The design of the incoming service from the distribution network operator (DNO), and associated 11kV distribution point, has been designed to offer both resilience and flexibility of operation. Maintenance and future replacement of equipment will be possible with little or no disruption to supplies.

Negotiations with the local DNO, Core Utilities (Scottish Power), have suggested that a primary transformer substation will be required to serve the whole South Glasgow Hospital site with separate incoming MV supplies at 33kV both originating from Braehead.

Ideally, dual supplies should originate, if possible, from separate DNO substations, ideally from separate parts of the National Grid with independent cable routes to the hospital site. Where separate MV supplies from separate substations are not available, additional standby generation resilience may be necessary to improve overall resilience.

Primary Transformer Substation

The HV network is supplied from the EHV network at Primary Substations utilising transformers of standard size and phase connection. Typically, twin 12/24MVA (or 20/40MVA) 33/11kV primary transformers feed a two section 11kV busbar. The transformers are to be oil filled and naturally ventilated.

Each incoming feeder is to be connected to a different busbar section. The incoming circuits operate in parallel with the bus section circuit-breaker normally closed. The plan area required will be approximately 18m x 30m (see drawing SK-008).

The DNO has suggested that the options for the establishment of a 33kV/11kV primary substation are:

- 1) New DNO primary substation on the site supplied, installed and operated by Scottish Power, with the client contributing to development costs.
- 2) New private primary substation on the site supplied, installed and operated by the client with Scottish Power supplying electricity at 33kV.

Option (1) is preferred and negotiations with Core Utilities (Scottish Power) are underway at this time to attempt to achieve this.

Metering breakers are to be located either side of a bus section switch. This arrangement will allow the PFI development and existing site to be metered separately and for the DNO to maintain their equipment without disruption to supplies.

The establishment of a primary substation, by the local DNO, with a robust incoming supply at 33kV and delivering power to the site at 11kV has the contractual advantage that the existing site distribution can be kept separate from the MV distribution required as part of the proposed PFI development. For the new PFI hospitals new utility electrical supplies and on site HV infrastructure will be provided. The drawings show new dual supplies coming into a new HV switch room in the energy centre, these are currently shown to serve the PFI site only. The source location of these is subject to the final proposal/agreement of Scottish Power. From the HV switch room the supplies are to feed local transformers positioned on two independent HV rings circling the new hospitals.

Electrical supplies to the PFI hospitals will be backed by on site standby generation.

Following the completion of the PFI construction phase the HV supply to the retained estate can be extended from the Surgical substation back to the new incoming HV switch room so as to provide a ring. Once the adult hospital is occupied a proportion of the retained estate becomes redundant, a new substation is to be installed to serve the remaining listed buildings (effectively replace the existing CMB substation that will be demolished). The existing supplies are to be reefed or made redundant as the related buildings are demolished

6.3.3 Fuel Natural Gas

Read in conjunction with drawings 3757/S32P/000-010, inserted in appendices A. These relay the approximate routes of the existing gas infrastructure

Natural Gas is required for space and water heating, some steam supply for humidification and potentially combined heat and power supply.

The existing site gas infrastructure is supplied from 9 no metered, mains connections; 5 from the Govan road; 2 from the A739 and 2 from Hardgate road. Existing supplies are all radial supplies and the buried distribution pipework is likely to be of a material and age that now requires replacement.

Prior to the commencement of the PFI construction phase a new boiler house is being constructed and the existing catering facility is to be moved off site. This allows for the existing boiler house to be decommissioned and the buildings within the PFI site boundary to be demolished with their existing gas supplies made redundant/removed.

It is currently proposed that the new PFI hospital buildings will be supplied from a new mains connection from Govan road. SGN have confirmed a budget price to provide this, we also understand this confirms that they have reviewed the additional load in relation to their infrastructure and have allowed for any necessary modification works within this budget price. This mains will be routed into the energy centre to feed the new heating and CHP plant (for both Children's and Adult's hospitals) and will then be routed via the underground tunnel to serve any local supplies e.g. autoclaves, humidifiers etc.

Following the completion of the PFI construction phase and the occupation of the new adult hospital, the redundant buildings on the site are to be demolished, with their related gas supplies made redundant and removed

6.3.4 Drainage (foul & surface)

Existing Drainage Networks/Strategies

The existing on-site drainage comprises of both stormwater and combined (foul) systems running generally north towards the entrance to the site to Govan Road. Both of these main drainage networks are not adopted by ScottishWater and are the responsibility of GG&CHB. Please refer to NE02355-C-800-P1 for indicative layouts.

There are a number of connections into these systems from outwith the site which contribute unknown quantities and flowrates of both foul and surface water into these systems. These connections are from the housing at the south of the site, the fast-food Dining area at Moss road and Hardgate road to the west of the site.

Existing Combined (foul) Drainage

The existing main combined (foul) drainage runs generally north-east across the Southern General site. The main pipe comprises of a 375dia vitrified clay pipe which outfalls from the site at Govan road before entering the adjacent Shieldhall treatment works. **Connections of both foul and surface water enter this pipe from developments across the existing site with many (?) being required to be maintained for future use. (Missing a word?)**

Existing Stormwater Drainage

The existing main stormwater drainage comprises of a 600dia pipe to the south of Langlands Drive and a 1200 x 950 brickwork egg pipe continuing from Langlands drive to the hospital perimeter. This network follows the same general route of the main combined (foul) pipe, running south to north before discharging at the adjacent to the Govan road entrance into an open channel and subsequently into the River Clyde. An existing 600dia stormwater pipe from Hardgate road forms a major branch in the stormwater network running east-west across the site.

Phase 1 Drainage Enabling Works

In order to ensure the continued operation of the existing drainage networks during the Phase 1 development works some drainage diversions are required. There are four drainage runs through the proposed site which must be maintained:

Obstetrics/Gynaecology – 150dia stormwater pipe

This pipe runs west to east and connects into the stormwater network running through the proposed Phase 1 development site. Due to lack of levels information it is not possible to definitively propose the route for this diversion. There are two options available which could ensure the satisfactory diversion of this pipe:

-Connection into an existing 225dia pipe to the south of the Maternity wards

-Diversion to the north-east across the boundary of the proposed Phase 1 development with connection into the existing 600dia pipe running from Hardgate road.

Main combined (foul) pipe - 375dia vitrified clay pipe

The diversion of this pipe is required from an existing manhole in Langlands road to the south and around the proposed facility. This will take the form of a 375dia concrete pipe with new manholes at changes of direction, connections to existing branch lines and provision for connections from the proposed facility. The layout of these proposed diversion works is shown indicatively on NE02355-C-801-P1.

Following these works the existing pipe will remain in its present configuration running west to east along the hospital access road before outfalling into the ScottishWater sewer in Govan road. Capacity assessments are currently being carried out by ScottishWater for the Shieldhall treatment works and the existing outfall will be re-used for all foul loadings from the new development and during the phased decent of facilities and personnel within the Southern General site.

Main stormwater pipe - 1200 x 950 brickwork egg pipe

As for the above combined (foul) drainage pipe diversion, the main stormwater run must also be diverted to avoid the south-east corner of the proposed new facility. The route of this diversion will typically follow the combined (foul) diversion along the existing and proposed site roads as shown indicatively on NE02355-C-801-P1. A 1200dia concrete pipe is to be used in order to match the existing capacity of the 1200 x 950 brickwork egg pipe.

Hardgate road – 600dia stormwater pipe

The diversion of this pipe is required around the northern edge of the proposed facility. Only minor diversion works involving two manholes and new 600dia concrete pipe is envisaged. Care must be taken during demolition works at the existing helipad to ensure the existing pipe is not damaged.

The diversion works for these drainage runs should also include the provision for new connection points from the proposed development works as appropriate. These are discussed further at the end of this section.

Proposed Storm and Foul Water Schemes/Strategies

The below ground drainage philosophy has been discussed with the local service provider, ScottishWater. The following section of this DSR outlines their anticipated key requirements and restrictions in order to comply with likely planning conditions and to ensure that their infrastructure can meet the needs of the new facility. The outline strategy proposals are shown indicatively on NE02355-C-802-P1.

Communications with ScottishWater have comprised both face to face meetings and written correspondence. ScottishWater is shortly due to submit to GG&CHB the findings of its assessment of the water supply and sewerage disposal implications at the site for the proposed facility. In the absence of confirmation of ScottishWater's formal findings and based upon existing knowledge of the site, the following anticipates their findings and conclusions.

Foul Water

Foul drainage from the proposed facility will utilise the diverted combined (foul) drain running across the HSGH site. As part of the diversion works connection manholes with tails into the new development should be provided at the north-east corner of the facility. Other connections into the 375dia combined (foul) pipe may be provided around the proposed facility subject to the layout design for the drainage around the building perimeter.

As the existing foul water from the site outfalls into this network, no capacity problems are envisaged. However, a reduction in the amount of stormwater entering this pipe as part of the demolition works of older buildings is expected to greatly outweigh the increase in foul discharge therefore allowing the capacity to be used for the new development. Confirmation from ScottishWater forthcoming report will however be required to confirm this assumption.

Stormwater

A site-wide strategy for managing stormwater across the entire site is required as part of the larger re-development works. At this stage the ability to incorporate this is restricted due to the space constraints imposed by adjacent operational buildings.

In order to comply with Planning regulations and the requirements of both ScottishWater and SEPA, the use of a “management train” approach to dealing with stormwater in a sustainable manner through the use of SUDS (Sustainable Drainage Systems) is required. This must be planned and designed in accordance with published best practice guidance (CIRIA C697 -The SUDS Manual). Appropriately designed, constructed and maintained SUDS are more sustainable than conventional drainage methods because they can mitigate many of the adverse effects of urban stormwater runoff on the environment.

They can achieve this through:

- Reducing runoff rates, thus reducing the risk of downstream flooding
- Reducing the additional runoff volumes and runoff frequencies that tend to be increased as a result of urbanisation, and which can exacerbate flood risk and damage receiving water quality
- Encouraging natural groundwater recharge (where appropriate) to minimise the impacts on aquifers and river baseflows in the receiving catchment
- Reducing pollutant concentrations in stormwater, thus protecting the quality of the receiving water body
- Acting as a buffer for accidental spills by preventing direct discharge of high concentrations of contaminants to the receiving water body
- Contributing to the enhanced amenity and aesthetic value of developed areas
- Providing habitats for wildlife in urban areas and opportunities for biodiversity enhancement.

To mimic natural catchment processes as closely as possible, a “management train” is required. This concept is fundamental to designing a successful SUDS scheme – with drainage techniques in series incrementally reducing pollution, flow rates and volumes of runoff. Through effective control of runoff at source, the need for large flow attenuation and flow control structures is reduced.

The variety of SUDS components and design options are wide ranging and the following should be incorporated where possible to help deal with contaminants and lower/slow the stormwater run-off:

- Source control techniques
- Rainwater harvesting systems – for roofwater re-use for toilets etc
- Filter trenches - to treat run-off from car parking areas
- Swales - to treat run-off from car parking areas
- Pervious pavements - to treat run-off from car parking areas
- Geocellular systems - for stormwater attenuation storage
- Detention basins- for stormwater treatment and attenuation storage
- Ponds- for stormwater treatment and attenuation storage
- Stormwater wetlands- for stormwater treatment and attenuation storage

The larger masterplan for the site includes the provision of a large wetland/pond which may be utilised for attenuation storage as part of the wider development. Due to the staging process of the development this will not be constructed and operational for use at this stage and therefore the use of source control (permeable pavements) and buried tank attenuation should be considered for use prior to discharge into the diverted on-site drainage network.

As the stormwater for the existing buildings and related hardstanding discharges into the existing stormwater network, this is to be reutilised for the proposed facility. The **peak stormwater flows** must be restricted to a worst case that matches the existing discharge rates into this network and ultimately to the River Clyde outfall. This ensures that compliance to the existing agreements with SEPA and ScottishWater for this discharge are not jeopardised. It is likely that Scottish Water and SEPA will accept that this flow into the public system will remain and no further works are required to attenuate this discharge.

It has not been established if Scottish Water/SEPA will restrict the discharge of stormwater from this part of the development to the equivalent flow generated from green-field stormwater run-off. Should this be required as part of these works then significant SUDS techniques incorporating stormwater attenuation will be required. However, there are proposals to provide a number of water features at the site and this would provide ideal attenuation facilities for this and future schemes as/if required in lieu of buried tanks located beneath external areas.

The use of suitable stormwater run-off SUDS treatment techniques may be used in car park areas in lieu of the need for a petrol interceptor. This must be agreed with SEPA. Should more conventional surfacing materials and drainage be utilised, a petrol interceptor should be incorporated to intercept hydrocarbons prior to discharging into stormwater network. This must be alarmed and connected to the facilities management system to ensure suitable maintenance is carried out.

6.3.5 Medical Gases

Read in conjunction with drawings 3757/OXP/000-010, inserted in appendices A. These relay the approximate routes of the existing site oxygen infrastructure

There is currently a centralised oxygen compound currently located behind the existing A&E building. A new compound is to be installed behind the maternity building and connected into the existing oxygen network; this allows the existing pipework that crosses the PFI to be removed prior to the construction phase commencing.

A new oxygen VIE compound is to be provided to supply the new adult and Children’s hospitals; a new ring will be installed around the new buildings.

Following the completion of the PFI construction phase and the occupation of the new adult hospital, the redundant buildings on the site are to be demolished, with their related oxygen supplies (fed from compound behind A&E) made redundant and removed. Should the retained existing buildings require oxygen supplies from the site infrastructure then an additional compound may be necessary to serve these.

Any existing requirements for Nitrous Oxides, Vacuum and Medical Air are supplied by local plant and these will be retained/removed in relation to the spaces they serve. Where these gasses are required by the new PFI project, a view will be taken on whether these are to be centralised or localised in relation to the areas served/demand.

6.3.6 IT

Read in conjunction with drawings 3757/ITP/000-010, inserted in appendices A. These relay the approximate routes of the existing site IT/data infrastructure

There are two main incoming data/telecoms rooms, one in the listed building with utility cables coming in from the A739 bypass road and the other in the Outpatients building with utility cables coming in from the Govan road.

Prior to the commencement of the PFI construction phase the buildings within the site boundary are to be demolished and existing data/telecoms connections made redundant/removed. Some cables cross the site e.g. serving maternity; these are to be rerouted using the existing ducting running towards Hardgate road.

The new PFI site is proposed to be connected back to both incoming telecoms/data rooms so that there are two separate routes back to the centralised equipment. The Children’s hospital is to be used as a location to house new equipment and in the long term this could replace that in the Outpatients building, which will be subsequently demolished post PFI construction. Alternatively the equipment in the Outpatients building will require rehousing when this building is demolished.

6.3.7 Steam/ Condensate

Read in conjunction with drawings 3757/T33/000-010, inserted in appendices B. These relay the approximate routes of the existing site steam infrastructure

The existing site is provided with a limited amount of steam (mainly for heating purposes) from the centralised boiler room. The Estates team have already made a considerable effort to decentralise the heating systems and move away from steam heating. A new steam boiler house is to be installed and connected into the existing steam and condensate mains system, this will allow the decommissioning of the existing boiler house prior to the PFI construction works commencing.

Prior to the commencement of the PFI construction phase the buildings within the site boundary are to be demolished and steam/condensate connections will be made redundant/removed.

Post PFI construction the existing steam heating system is to be reviewed in relation to which areas of the retained buildings use the steam heating. Modifications to the steam system will either then be made accordingly or new LTHW plant installed, allowing the buildings that are to be demolished to be so and their related steam/condensate pipes removed. **This is particularly relevant to the Listed building.** Needs an explanatory sentence to make explicit why it is relevant?

6.3.8 Adaptability and Capacity for Expansion

The schemes above have allowed for future expansion based on the Campus Plan submitted by the Trust for planning in the Winter 2006 and are as follows:

WATER

For the site, this can be analysed once Scottish Water have completed their demand and infrastructure modelling. It is envisaged that the later phases of demolition (post PFI connection) will release existing capacity/usage from the Govan road supplies and the A739 (Moss road) supply. These and/or a connection from the new PFI supply from Govan road could then offer some capacity to provide single feed supplies to the future expansion spaces indicated on the drawings.

The new labs building (planned for construction pre PFI) will also need consideration in relation to the above, this is to be included when Scottish water complete their analysis.

POWER

For the site, in our discussions with Scottish Power we have allowed for a future site capacity (post PFI construction and demolition) of 15kVA. However Scottish Power is considering this in relation to the site wide supply and thus the final solution when agreed with Scottish Power may differ from the strategy outlined above and indicated on the drawings. This is therefore subject to further discussions and feedback from Scottish Power.

For the PFI hospitals, electrical power consumption is likely to rise over the PFI term as electrical equipment and IT usage increase that will result in a corresponding increase in the requirement for spot cooling. Load increases are more likely in the clinical “hot” areas rather than the ward areas. We have included +20% increase from the initial load to MD as HTM 06-01 (Table 2 “Growth Factor”) included within the 15MVA site load and 10MVA associated with the PFI Hospitals and allowed for in the design of the incoming supply switchgear and MV distribution to the hospitals to provide scope for additional supply needs without a major refit.

Greater low or zero carbon electrical and heat generation are likely over the PFI term to reduce carbon emissions from the hospital and as the cost of energy rises, alternatives such as on site generated energy may become economic, eg PV cells, additional or hydrogen based CHP. The centralised energy centre provides an adaptable infrastructure that will be able to respond to these changing needs and circumstances.

NATURAL GAS

For the site, the quotation/confirmation from SGN Connections is an additional load to that of the current existing infrastructure. The pre and post PFI building demolition will release existing capacity/usage from the existing Govan road supplies; these can then provide supplies to the future expansion spaces indicated on the drawings. The load for the new labs building has not been included in our discussions with SGN.

For the PFI hospitals we do not see gas consumption rising significantly over the PFI term. It is likely that the nature of the supplied gas will change over the PFI term as natural gas is replaced by synthetic or “biogas” and that the installations will need to be adapted at this time.

MEDICAL GASES

For the site, should the future expansion spaces require oxygen to be supplied from the centralised plant, then the existing plant located behind the existing A&E building will become redundant at that time. This, therefore, provides capacity to supply these areas and to link into the existing site network as required. This is also a strategy that may be able to serve the Labs building.

IT

The incoming data/telephone lines and centralised equipment capacity are to be reviewed and defined by the client's specialists.

ENVIRONMENTAL STRATEGY AND APPROACH TO INTEGRATED DESIGN

The environmental strategy is based on:

- good environmental conditions are required for staff, patients and visitors
- energy use is to be minimised using systems and plant most appropriate to the hospital environment. As a starting point total energy use including small power and medical equipment loads are not to exceed 55GJ/100cm in any year (delivered energy).
Ongoing energy reductions should at least ensure that energy use per unit volume or area do not increase with time and offset additional load as use changes/develops.
- 20% of the energy use above is to be “low or zero carbon” as defined by the Scottish Building Regulations
- Every five years, the contribution of energy reduction and low or zero carbon energy as a percentage of total consumption is to be increased by five percent.
- system and plant/component selection is to be based on lowest life cycle cost

In order to produce robust solutions the design follows the following hierarchy:

- Make the building energy use as low as possible by investing in the building fabric. This will have a good payback as the building fabric life is long and the installations are not dynamic requiring little additional maintenance over and above standard typical solutions
- select appropriate environmental strategies. Design the building so that it offers flexibility to meet changing needs and economic and social drivers with success in the future

The environmental strategy is based on a sealed building with mechanical ventilation. This follows from an appraisal of the ventilation options for Ward Areas presented to the client in March 2007 which attempted to explain and balance the competing design and operational drivers.

To accommodate the extensive vertical and horizontal services runs that will be required for the new hospital facility both in the tower and podium areas as well as to the laboratory block, the design should take due cognisance of this requirement and for the availability of services openings, corridors/routes and penetrations.

Services routes should be fully integrated with the structural design for the buildings to ensure proactive inclusion to accommodate the full extent and range of service types, services proximity, future adaptations and maintenance. This should address issues including wall and floor penetrations, floor and ceiling routing, protection and containment and to ensure that all structural load paths remain uncompromised under all circumstances.

The establishment of the requirements for the provision of dedicated services routes between different hospital buildings and within separate parts of the adults and Children’s facility should be adopted at an early stage of the design to ensure that full effectiveness and interoperability of all plant rooms, roof mounted equipment, basement plant and link corridors is achieved.

The services strategy should allow for the requirements of the facilities energy centre, electrical sub-stations, gas pressure reduction stations, gas/fire suppressant bottle stores, water tanks, HVAC equipment, helicopter servicing, fire-systems, steam and other mechanical services including all specialist services i.e. medical gases.

The structural building frame that is adopted should be selected on the basis of other site constraints to allow planned and pro-active inclusion for services routes and plant room sizing and location.

6.3.9 Ventilation

Required Conditions

It is important that the ventilation approach for the Adult and Children’s hospitals fulfil the primary requirement to provide adequate:

- supplies of fresh air
- odour dilution
- removal of airborne contaminants or pathogens

Detailed quantified requirements relating to internal environmental conditions can be found in Department of Health Estates & Facilities Division publications. These publications are in the process of being rationalised. The current ventilation standard SHTM 2025 will shortly be superseded by HTM 03-01 ‘specialised ventilation for healthcare properties’. A draft version of this new standard has been circulated. The HVAC design is in accordance with its requirements.

Site Constraints

It is important that the ventilation approach takes into consideration the constraints of the site. These have been identified as:

Smells from adjacent sewage treatment plant

Scottish Water’s Sheildhall Sewage Treatment Plant lies approximately 400m north of the site. Staff and patients using the existing hospital buildings on the site experience a constant low-level of odour from the plant. After heavy rain the odour becomes more pronounced and unpleasant. Although there are intentions to remedy or re-locate the sewage treatment plant, there are no concrete plans or timeframe for this work. There is a major risk, therefore, that the odour issue will not be resolved before the opening of the Hospitals. SHTN 30 ‘Infection Control in the Built Environment’ states that although odour in itself does not present a direct risk, if it leads to ventilation being restricted it may in turn increase the risk of hospital acquired infections.

Construction noise, dust & contamination

The construction of the Adult and Children’s Hospitals is to be staggered. This means that there will be a period when the Children’s’ Hospital is operating and the Adult Hospital is being built. It is important that the ventilation approach limits the intrusion of construction noise, dust and contamination while ensuring adequate ventilation.

It is important that the laboratories on the site do not contaminate ventilation air drawn into the new hospitals. A detailed site airflow assessment needs to be carried out to confirm that this will not be an issue.

Mechanical Ventilation

The Clinical Areas, Wards and the remainder of the main hospital buildings are to be mechanically ventilated throughout. This decision has been made because mechanical ventilation offers the following advantages over natural ventilation:

- smells can be eliminated from incoming air through activated carbon filtration.
- dust can be filtered from incoming air.
- external noise from site construction can be attenuated through the incoming air path
- for clinical areas robust and reliable control of environmental conditions is required for the spaces to function correctly and efficiently. The control airborne infection by room air flow control and dilution by enclosure and mechanical ventilation is essential.

Additionally mechanical ventilation provides the additional benefits of:

- helping to control airborne infection by allowing points of air intake and discharge to be carefully separated to avoid recirculation, good dilution of room contaminants/pathogens, and by allowing pressure differentials to be created to facilitate the flow of air from clean to less clean areas.
- allowing air to air ventilation heat recovery, thereby significantly reducing the running costs and carbon emissions associated with space heating and cooling of ventilation air.
- allowing incoming air to be cooled prior to being supplied to spaces to ensure good thermal conditions. This provides a system that for patient and staff areas do not exceed the draft HTM 04-01. This recommends that temperatures of 28°C are not exceeded for 50 hours a year.
-

In addition, as the heliport is to be constructed on the roof of the Adult Hospital tower, mechanical ventilation will avoid drafts through windows and help limit noise.

High building air tightness is required to exclude infiltration and odour. The buildings will be slightly pressurised.

Energy Reduction Measures

The Hospitals are to incorporate the following measures to reduce energy consumption associated with HVAC systems:

- windows in ward and office areas are to be fitted with external adjustable shading devices such as adjustable mid pane louveres or blinds. These will reduce peak solar heat gains to allow good thermal conditions within well day lit spaces and minimize the requirement for mechanical cooling in these areas. Shading Factor “SF” > 70%.
- exposed thermal mass, where practical, to limit temperature swing and reduce peak temperatures. Patient rooms are to have exposed concrete soffits.
- air to air heat recovery in all air handling units.
- variable ventilation rates by fan speed control for spaces with demand control (eg odour, ammonia)

General Plant Design & Distribution for Infection Control

Each hospital department is to contain its own dedicated air handling plant. Larger departments, such as inpatient wards, are to be zoned with separate air handling plant serving each zone. This is to ensure that in the event of mechanical failure, or during maintenance or refurbishment only a limited area is affected. Critical care units are to be served with back-up air handling plant.

Air handling plant at podium roof level are to serve the main body of the hospitals as well as the lower half of the adult hospital tower. The top half of the tower is to be served by air handling plant installed in the tower roof. Fresh air intake and discharge louveres are to be installed at these levels, carefully separated to avoid recirculation.

Supply and extract ductwork is to be distributed to the hospital departments via risers. Where possible these risers are to be located off main circulation routes to facilitate access for cleaning and maintenance. Horizontal distribution is to be in ceiling voids above corridors, wherever possible, so that access panels can be located outside clinical areas. Similarly, trimmer coils are to be installed above circulation areas wherever possible to avoid potential leaks in clinical areas, which would lead to greater disruption and potential damage to expensive equipment.

The ductwork distribution system is to be a low pressure system. Smoke dampers will be installed through all fire and smoke compartments. Access panels are to be installed in accordance with DW142 to allow adequate inspection, maintenance and cleaning. Flexible ductwork is only to be installed for final connections to grilles and diffusers.

Diffusers and grilles are to be carefully chosen to allow them to be easily removed and cleaned to limit airborne contamination.

Air handling plant is designed to comply with draft HTM 03-01 requirements, and includes, in addition to the base provision of inlet filter, heating coil and fan/attenuators the following:

- inspection, cleaning and maintenance access sections either side of all coils and dampers, upstream of all filters and downstream of all humidifiers.
- blow-through configuration of fans to ensure as much of the unit is under positive pressure as possible.

The following sections are generally to be incorporated into all air handling units:

- fog coils.
- cooling coils
- temporary pre-filters (G1/G2) to allow removal of dust while construction work is ongoing.
- steam injection humidifiers
- activated carbon filters for odour removal

Specialist Ventilation Areas

wards

Ventilation plant will be zoned by elevation and space type/function.

Patient rooms and multi-bed bays are to have local temperature control through the installation of heating trimmer coils on individual room branch pipework. Space humidification and cooling will be by the supply of cooled ventilation air without

individual room temperature control In individual rooms temperature and external motorized solar shading control is to be built into the bed-head controls. In multi-bed bays controls are to be installed at a central location. Temperature control is be primarily automatic with sensors in each space, however local controls are to allow limited adjustment of the set-point for a limited period after which the temperature control returns automatically to its pre-set set-point.

Patient rooms and multi-bed bays are to be kept at a lower pressure relative to their adjacent corridors, and so in addition to the air supplied directly to these spaces additional air will pulled in under doors. Air is to be extracted through ensuite shower rooms as well as additional grilles located above the ensuite shower room doors. The air change rate in these spaces is to achieve the draft HTM 03-01 requirement of six air changes per hour. However, apart from specific wards where clinical experience indicates that odours are likely to be strong and persistent, such as the geriatrics wards, the controls are to set the air change rate at four air changes per hour with local pushbuttons to allow the rate to be boosted to six air changes per hour for a limited period. Buttons are to include bypass key control to allow the air change rate to be locked at six air changes per hour if this proves desirable.

critical and intensive care

These are to be air conditioned spaces with full temperature and humidity control.

operating suites

Each conventional operating suite is to be installed with its own air handling unit. Fresh air is to be delivered in accordance with draft HTM 04-01 at 25 air changes an hour. Operating suites are to be controlled in such a way so that when vacant, ventilation plant is turned off to conserve energy. In the operating theatre air is to be supplied through the high-level terminal canopy and expelled at low-level through pressure stabilizers. Pressure stabilizers are to be installed on all four sides or in all four corners of the room, and to be visible so that they provide a visual indication that the ventilation system is running.

Ultra clean ventilation operating suites are to be delivered with the same amount of fresh air as conventional suites, however an additional recirculation air handling unit is to be installed to increase the flow through the terminal to ensure laminar flow and a count of less than 1 colony forming unit per cubic meter. A high-efficiency HEPA filter is to be installed before the canopy. The recirculation unit is to be remote, to allow inspection and maintenance to be carried out outside the theatre. The canopy is to be of the vertical flow type.

isolation suites

Isolation suites will be dedicated plant designed as HBN 4 Supplement 1 to provide isolation. This relies on an air tight enclosure and a lobby positively pressurised with respect to the room and corridor.

Ventilation System & Fire Strategy

In certain critical care departments it is preferable to maintain the supply ventilation in the case of a fire within the area, for example the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke. The ventilation plant is not designed to be automatically shut down on the operation of the fire alarm and detection system, but under the instruction of the fire-and-rescue service and controlled from panels located either at department entrances or adjacent to the main fire alarm indicator panels at the entrances to the buildings.

Fire dampers are to be installed in all ducts penetrating fire compartment and sub-compartment walls. In compartment walls fire dampers are to be actuated on the operation of the alarm and detection system in the compartments either side of the compartment walls. In sub compartment walls dampers are to be activated by thermal release devices.

All supply AHU's are to have a smoke sensor mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source the supply air damper is to close and the AHU is to be shut down.

A mechanical smoke extract system is to be installed in the basement of the hospitals. (The installation of a sprinkler system in the basement allows mechanical smoke extract to be considered as an alternative to conventional smoke vents.) This system is to provide at least ten air changes per hour and be capable of handling gas temperatures up to 400°C for an hour.

6.3.10 Heating

HOSPITAL INFRASTRUCTURE

Central Boilers & distribution

The plant for both the Adult and Children's Hospital is to be centralised and located in a separate Energy Centre. The system philosophy is shown on SK021. The plant shown will provide heating for fabric, ventilation and domestic hot water needs for the two hospitals. Separate steam generation plants will be required for humidification and sterilisation.

The heating system located in the Energy Centre will be a Medium Temperature Hot Water System (140/65 °C). The boilers to be used are high efficiency, low Nox, 3 pass high water content boilers with pressurised burners that operate on alternative fuel supplies of natural gas and 35 second light oil. Burners to be digital modulating with variable speed and air damper control capacity control to achieve a high turndown ratio (10 to 1 turndown on natural gas). Low NOx (<70mg/KWhr natural gas) burner with oxygen trim control.

The boiler configuration employs an effective (N+1) redundancy at peak connected design load (effective N+2 at part load). Each boiler is to have its own discreet insulated and clad flue. The flue stack to be an independent stainless structure to allow the flue to discharge above the level of the tower with space to accommodate other services requiring high level discharge.

The MTHW will be distributed via separate highly insulated district heating mains to the Adult and Children's Hospitals run within the basement service route between the Energy Centre/Loading Bay and the Hospitals. Heat exchangers convert the MTHW to LTHW (90/70 °C) locally for room heat emitters and air trimming coils.

It is envisaged that the pipework installation will consist of a mixture of modern and traditional materials. The whole of the heating system will be chemically dosed and treated as appropriate. All pipework and fittings are to be highly insulated to minimise heat loss and heat gain to the hospital spaces. Insulation will be 50% thicker than the minimum economic thickness.

All pumping arrangements will include redundant standby pumping. The majority of the main pump sets will consist of 3 no. pumps rated at 50% duty while the smaller pump sets will consist of smaller run and standby pumps rated at 100% duty.

In order to optimise energy usage 2 port control valve technology and variable speed pumping will be employed throughout. Differential pressure control valves shall be used on all sub-circuit branches.

Gas Combined Heat and Power

At present a 1.5 MWe gas supplied spark ignition reciprocating engine combined heat and power installation has been included in the base scheme. The exact size of the CHP plant will be reviewed once detailed electrical and heat load analyses have been completed for the site and the economic case for CHP can be explored in detail with a turnkey operator. Additional CHP capacity in the future provides scope for increasing the proportion of "low carbon " energy supply.

The CHP unit is to be located in the Energy Centre. Heat will be recovered from the unit engine jacket, engine cooling system and exhaust gases via a shunt pump circuit connected to the main boiler return distribution pipework. Once the exact size of the unit is known it may be beneficial to employ a separate heat recovery boiler. The CHP unit will have its own separate flue. It is envisaged that the unit will operate whenever the heat and power can be fully utilised.

Domestic Hot and Cold Water

The domestic hot and cold water installations will be installed to potable quality standards throughout the whole of the Hospital development.

There shall be dual and separate water supplies to the Adult and Children's Hospitals. The total hot and cold water needs for each building shall be met by water storage located in each building. Each building shall have sufficient water storage to meet 24 hours requirement. The preferred option for the water storage and distribution is as follows.

- Main storage tanks located in basement, no break tanks, pumped distribution system, with duty standby pump sets and controls and generator back electrical supplies to the pumps. Trust approval for this option will be required.

The location and number of independent hot water heat stations is shown on SK023. Each heat station location is sized on a (N+1) basis. Hot water shall be delivered to individual wards and departments via a traditional two pipe circulation system.

The whole of the potable hot and cold water installation will be designed to meet all the legionella requirements. In particular the water storage tank connection arrangements allow for zero dead legs and the heat station installation allows for continual calorifier circulation with zero stratification. All pipework is to be insulated to minimise heat loss or gain as appropriate.

Particular emphasis is to be put into ensuring that there will be the minimum number of hot water returns, that there will be adequate insulation on the cold water installations to avoid temperature build up and that there will be regular flushing of cold water dead legs by means of appliances connected to the same.

The laboratory areas will be provided with similar hot and cold water installations employing separate break tanks and separate calorifiers to ensure full segregation between laboratory and domestic installations thus meeting the requirements of the Water Regulations.

Pipework installation within both hospitals will be run within individual level ceiling voids to ensure any particular ward or department can be isolated at that level only.

Room Heat Emitters

Where room are mechanically ventilated heating and ventilation rates are sufficient to provide good room air mixing/destratification, heating will be provided by air room reheat coil with 2 port water control valve and room temperature controller.

For areas with extensive glazing and/or natural ventilation, heating will be from perimeter heating; either high level radiant panel or low level convector.

6.3.11 Cooling

General Chilled Water

In order to meet the annual cooling requirements of the development and the requirements of HTM 3, chilled water installation will be required.

The preferred chilled water system configurations are shown on SK019.

- The configuration shows discreet chiller installations adjacent to the air handling units they serve. As a (N+1) redundancy philosophy has been utilised for each chiller cluster, a separate process chilled water system will be installed utilising free cooling chillers.

The chilled water equipment shall include chillers, buffer vessels and pressurisation units. Each chiller will be of the fully packaged air-cooled type complete with multiple modular screw compressors. The chiller will be rated as residentially quiet to avoid unobtrusive noise emissions. Chillers to have variable speed head pressure control with load and efficiency optimised head pressure and chilled water flow temperature control to improve seasonal efficiency.

The chilled water circuits will consist of both primary and secondary pumping. In order to optimise energy usage, 2 port control valve technology and variable speed pumping will be employed throughout. Differential pressure control valves shall be used on all sub-circuit branches.

All pumping arrangements will include redundant standby pumping. The majority of the main pump sets will consist of 3 no. pumps rated at 50% duty while the smaller pump sets will consist of smaller run and standby pumps rated at 100% duty.

Chilled water will be distributed through a conventional 2 pipe system to the various demand centres throughout the building. The installation will employ a number of traditional and modern materials. The entire chilled water system will be chemically dosed and treated as appropriate. All pipework is to be insulated to minimise gain.

ITC Cooling

Independent chilled water system as above but with free cooling roof mounted air cooled water chillers. N+2 redundancy with plant backed by the essential electrical supply.

6.3.12 Drainage

The rainwater drainage system in each hospital shall be gravity systems. The rainwater pipework in each hospital shall be housed in vertical risers and will be insulated to prevent condensation and noise transfer.

The soil and waste drainage system in each hospital shall be gravity systems. The systems generally shall be vented to atmosphere above the roof. It is envisaged that the pipework installation will consist of a mixture of modern and traditional materials. Separate chemically resistant drainage will be installed in all specialist areas.

6.3.13 Artificial Lighting

General lighting to all areas by low energy fluorescent light sources. All control gear to be high frequency, high power factor (PF>0.95), low harmonic emission light fittings equipped with electronic control gear. No switch start gear light fittings permitted.

Efficient light sources and luminaires will be used.

Lighting is a substantial user of energy in hospitals and buildings generally. Often the light level and energy use can be varied because natural light is available or because the need for light is reduced. In summer the removal of heat from light fittings is important to prevent overheating of spaces. As lamps age and fittings/lamps get dirty over their cleaning cycle, the light output will fall. Room photocells and dimming can adjust the output of the lamp down when clean, to reduce energy use and heat gain. For each space the potential for lighting controls will be examined and the appropriate lighting controls will be installed.

Lamp and lighting gear monitoring provides a cost effective solution to lamp/gear maintenance.

day lit spaces	fitting dimming controls and room photocells to provide dimming and off control
spaces subject to intermittent occupancy	occupancy detection to switch lights off when the room is not in use
all spaces	fitting dimming controls and room photocells to provide lamp output control as lamps age/fittings get dirty lamp and gear monitoring and alarming for lamp/gear maintenance
external lighting	time and light level control of all external lighting

Design Light Levels:

as HTM/HBN & CIBSE guidance

Lighting Circuits:

Final circuit cabling shall generally consist of LSF insulated single core cables to BS7211 enclosed and protected within metal conduit. All final circuits shall be provided with full size single core circuit protective conductors.

All electrical accessories/socket outlet switch plates shall be stainless steel finish in Category 3, 4 and 5 areas. Offices and administration (non-patient areas) could be of alternative materials (i.e. plastic).

Escape light fittings throughout the building wards will be supported by the secondary power supply system with fittings distributed over at least two (Side A and Side B) interleaved circuits. In the event of a failure on Side A (final circuit, rising busbar, distribution board, main switch panel or supply transformer), then power will still be available from socket outlets connected to Side B circuits.

V40 Emergency Lighting

Generally, secondary lighting to Grade A or Grade B will be provided to all areas of the building depending on clinical risk category. All secondary lighting will be fed from the secondary power power supply (SPS) with reconnection within 15 seconds, following failure of the incoming mains supply (see drawing: V[20]-500). In accordance with HTM 06-01, all areas that require standby lighting will also be provided with emergency lighting.

Emergency escape lighting will be provided to all areas of the buildings to meet the requirements of BS5266 and HTM2011 Generally, emergency lighting will be provided in the form of self contained light fittings with their own integral battery packs to provide up to three hours autonomy in the event of complete power failure.

STATUTORY INSTRUMENTS

2002 No. 2677**HEALTH AND SAFETY****The Control of Substances Hazardous
to Health Regulations 2002**

<i>Made</i>	- - - -	<i>24th October 2002</i>
<i>Laid before Parliament</i>		<i>31st October 2002</i>
<i>Coming into force</i>	- -	<i>21st November 2002</i>

The Secretary of State being the Minister designated⁽¹⁾ for the purpose of section 2(2) of the European Communities Act 1972⁽²⁾ in relation to the abolition of restrictions on the import or export of goods, in the exercise of the powers conferred on him by the said section 2(2) and sections 15(1), (2), (3)(b), (4), (5)(b), (6)(b) and (9), 52(2) and (3) and 82(3)(a) of, and paragraphs 1(1) to (4), 2, 6(1), 8, 9, 11, 14, 15(1), 16 and 20 of Schedule 3 to, the Health and Safety at Work etc. Act 1974⁽³⁾ (“the 1974 Act”) and of all other powers enabling him in that behalf and for the purpose of giving effect without modifications to proposals submitted to him by the Health and Safety Commission under section 11(2)(d) of the 1974 Act after the carrying out by the said Commission of consultations in accordance with section 50(3) of that Act, hereby makes the following Regulations:

Citation and commencement

1. These Regulations may be cited as the Control of Substances Hazardous to Health Regulations 2002 and shall come into force on 21st November 2002.

Interpretation

2.—(1) In these Regulations—

“the 1974 Act” means the Health and Safety at Work etc. Act 1974;

“the Agreement” means the Agreement on the European Economic Area signed at Oporto on 2nd May 1992 as adjusted by the Protocol signed at Brussels on 17th March 1993⁽⁴⁾ and adopted as respects Great Britain by the European Economic Area Act 1993⁽⁵⁾;

(1) [S.I. 1992/2661](#).

(2) [1972 c. 68](#), the definition of the Treaties referred to in section 2(2) of the European Communities Act 1972 was extended by section 1 of the European Economic Area Act [1993 \(c. 51\)](#).

(3) [1974 c. 37](#), sections 11(2), 15(1) and 50(3) were amended by the Employment Protection Act [1975 \(c. 71\)](#), Schedule 15, paragraphs 4, 6 and 16(3) respectively.

(4) The Agreement was amended by Decision 7/94 of the EEA Joint Committee of 21st March 1994 (OJ No. L160, 28.6.94, p. 1). There are other amendments to the Agreement not relevant to these Regulations.

“appointed doctor” means a registered medical practitioner appointed for the time being in writing by the Executive for the purpose of these Regulations;

“approved” means approved for the time being in writing;

“approved classification” of a biological agent means the classification of that agent approved by the Health and Safety Commission;

“approved supply list” has the meaning assigned to it in regulation 2(1) of the CHIP Regulations;

“biological agent” means a micro-organism, cell culture, or human endoparasite, whether or not genetically modified, which may cause infection, allergy, toxicity or otherwise create a hazard to human health;

“carcinogen” means—

- (a) a substance or preparation which if classified in accordance with the classification provided for by regulation 4 of the CHIP Regulations would be in the category of danger, carcinogenic (category 1) or carcinogenic (category 2) whether or not the substance or preparation would be required to be classified under those Regulations; or
- (b) a substance or preparation—
 - (i) listed in Schedule 1, or
 - (ii) arising from a process specified in Schedule 1 which is a substance hazardous to health;

“cell culture” means the in-vitro growth of cells derived from multicellular organisms;

“the CHIP Regulations” means the Chemicals (Hazard Information and Packaging for Supply) Regulations 2002⁽⁶⁾;

“control measure” means a measure taken to reduce exposure to a substance hazardous to health (including the provision of systems of work and supervision, the cleaning of workplaces, premises, plant and equipment, the provision and use of engineering controls and personal protective equipment);

“employment medical adviser” means an employment medical adviser appointed under section 56 of the Health and Safety at Work etc. Act 1974;

“the Executive” means the Health and Safety Executive;

“fumigation” means an operation in which a substance is released into the atmosphere so as to form a gas to control or kill pests or other undesirable organisms and “fumigate” and “fumigant” shall be construed accordingly;

“Group”, in relation to a biological agent, means one of the four hazard Groups specified in paragraph 2 of Schedule 3 to which that agent is assigned;

“hazard”, in relation to a substance, means the intrinsic property of that substance which has the potential to cause harm to the health of a person, and “hazardous” shall be construed accordingly;

“health surveillance” means assessment of the state of health of an employee, as related to exposure to substances hazardous to health, and includes biological monitoring;

“inhalable dust” means airborne material which is capable of entering the nose and mouth during breathing, as defined by BS EN 481 1993;

“maximum exposure limit” for a substance hazardous to health means the maximum exposure limit approved by the Health and Safety Commission for that substance in relation to the

(5) 1993 c. 51.

(6) S.I. 2002/1689.

specified reference period when calculated by a method approved by the Health and Safety Commission;

“medical examination” includes any laboratory tests and X-rays that a relevant doctor may require;

“member State” means a State which is a Contracting Party to the Agreement;

“micro-organism” means a microbiological entity, cellular or non-cellular, which is capable of replication or of transferring genetic material;

“mine” has the meaning assigned to it by section 180 of the Mines and Quarries Act 1954⁽⁷⁾;

“occupational exposure standard” for a substance hazardous to health means the standard approved by the Health and Safety Commission for that substance in relation to the specified reference period when calculated by a method approved by the Health and Safety Commission;

“personal protective equipment” means all equipment (including clothing) which is intended to be worn or held by a person at work and which protects that person against one or more risks to his health, and any addition or accessory designed to meet that objective;

“preparation” means a mixture or solution of two or more substances;

“public road” means (in England and Wales) a highway maintainable at the public expense within the meaning of section 329 of the Highways Act 1980⁽⁸⁾ and (in Scotland) a public road within the meaning assigned to that term by section 151 of the Roads (Scotland) Act 1984⁽⁹⁾;

“registered dentist” has the meaning assigned to it in section 53(1) of the Dentists Act 1984⁽¹⁰⁾;

“relevant doctor” means an appointed doctor or an employment medical adviser;

“respirable dust” means airborne material which is capable of penetrating to the gas exchange region of the lung, as defined by BS EN 481 1993;

“risk”, in relation to the exposure of an employee to a substance hazardous to health, means the likelihood that the potential for harm to the health of a person will be attained under the conditions of use and exposure and also the extent of that harm;

“the risk assessment” means the assessment of risk required by regulation 6(1)(a);

“safety data sheet” means a safety data sheet within the meaning of regulation 5 of the CHIP Regulations;

“substance” means a natural or artificial substance whether in solid or liquid form or in the form of a gas or vapour (including micro-organisms);

“substance hazardous to health” means a substance (including a preparation)—

- (a) which is listed in Part I of the approved supply list as dangerous for supply within the meaning of the CHIP Regulations and for which an indication of danger specified for the substance is very toxic, toxic, harmful, corrosive or irritant;
- (b) for which the Health and Safety Commission has approved a maximum exposure limit or an occupational exposure standard;
- (c) which is a biological agent;
- (d) which is dust of any kind, except dust which is a substance within paragraph (a) or (b) above, when present at a concentration in air equal to or greater than—
 - (i) 10 mg/m³, as a time-weighted average over an 8-hour period, of inhalable dust, or
 - (ii) 4 mg/m³, as a time-weighted average over an 8-hour period, of respirable dust;

⁽⁷⁾ 1954 c. 70, section 180 was modified by S.I. 1974/2013, 1993/1897 and 1999/2024.

⁽⁸⁾ 1980 c. 66.

⁽⁹⁾ 1984 c. 54.

⁽¹⁰⁾ 1984 c. 24.

- (e) which, not being a substance falling within sub-paragraphs (a) to (d), because of its chemical or toxicological properties and the way it is used or is present at the workplace creates a risk to health;

“workplace” means any premises or part of premises used for or in connection with work, and includes—

- (a) any place within the premises to which an employee has access while at work; and
- (b) any room, lobby, corridor, staircase, road or other place—
 - (i) used as a means of access to or egress from that place of work, or
 - (ii) where facilities are provided for use in connection with that place of work, other than a public road.

(2) In these Regulations, a reference to an employee being exposed to a substance hazardous to health is a reference to the exposure of that employee to a substance hazardous to health arising out of or in connection with work at the workplace.

(3) Where a biological agent has an approved classification, any reference in these Regulations to a particular Group in relation to that agent shall be taken as a reference to the Group to which that agent has been assigned in that approved classification.

Duties under these Regulations

3.—(1) Where a duty is placed by these Regulations on an employer in respect of his employees, he shall, so far as is reasonably practicable, be under a like duty in respect of any other person, whether at work or not, who may be affected by the work carried out by the employer except that the duties of the employer—

- (a) under regulation 11 (health surveillance) shall not extend to persons who are not his employees; and
- (b) under regulations 10, 12(1) and (2) and 13 (which relate respectively to monitoring, information and training and dealing with accidents) shall not extend to persons who are not his employees, unless those persons are on the premises where the work is being carried out.

(2) These Regulations shall apply to a self-employed person as they apply to an employer and an employee and as if that self-employed person were both an employer and an employee, except that regulations 10 and 11 shall not apply to a self-employed person.

(3) The duties imposed by these Regulations shall not extend to the master or crew of a sea-going ship or to the employer of such persons in relation to the normal shipboard activities of a ship’s crew under the direction of the master.

Prohibitions relating to certain substances

4.—(1) Those substances described in Column 1 of Schedule 2 are prohibited to the extent set out in the corresponding entry in Column 2 of that Schedule.

(2) The importation into the United Kingdom, other than from another member State, of the following substances and articles is prohibited, namely—

- (a) 2-naphthylamine, benzidine, 4-aminodiphenyl, 4-nitrodiphenyl, their salts and any substance containing any of those compounds in a total concentration equal to or greater than 0.1 per cent by mass;
- (b) matches made with white phosphorus,

and a contravention of this paragraph shall be punishable under the Customs and Excise Management Act 1979⁽¹¹⁾ and not as a contravention of a health and safety regulation.

(3) A person shall not supply during the course of or for use at work a substance or article specified in paragraph (2).

(4) A person shall not supply during the course of or for use at work, benzene or a substance containing benzene unless its intended use is not prohibited by item 11 of Schedule 2.

Application of regulations 6 to 13

5.—(1) Regulations 6 to 13 shall have effect with a view to protecting persons against a risk to their health, whether immediate or delayed, arising from exposure to substances hazardous to health except—

- (a) where and to the extent that the following Regulations apply, namely—
 - (i) the Coal Mines (Respirable Dust) Regulations 1975⁽¹²⁾,
 - (ii) the Control of Lead at Work Regulations 2002⁽¹³⁾,
 - (iii) the Control of Asbestos at Work Regulations 2002⁽¹⁴⁾;
- (b) where the substance is hazardous to health solely by virtue of its radioactive, explosive or flammable properties, or solely because it is at a high or low temperature or a high pressure;
- (c) where the risk to health is a risk to the health of a person to whom the substance is administered in the course of his medical treatment.

(2) In paragraph (1)(c) “medical treatment” means medical or dental examination or treatment which is conducted by, or under the direction of a—

- (a) registered medical practitioner;
- (b) registered dentist; or
- (c) other person who is an appropriate practitioner for the purposes of section 58 of the Medicines Act 1968⁽¹⁵⁾,

and includes any such examination or treatment conducted for the purpose of research.

Assessment of the risk to health created by work involving substances hazardous to health

6.—(1) An employer shall not carry out work which is liable to expose any employees to any substance hazardous to health unless he has—

- (a) made a suitable and sufficient assessment of the risk created by that work to the health of those employees and of the steps that need to be taken to meet the requirements of these Regulations; and
 - (b) implemented the steps referred to in sub-paragraph (a).
- (2) The risk assessment shall include consideration of—
- (a) the hazardous properties of the substance;
 - (b) information on health effects provided by the supplier, including information contained in any relevant safety data sheet;
 - (c) the level, type and duration of exposure;

(11) 1979 c. 2.

(12) S.I. 1975/1433, as amended by S.I. 1978/807.

(13) S.I. 2002/2676.

(14) S.I. 2002/2675.

(15) 1968 c. 67.

- (d) the circumstances of the work, including the amount of the substance involved;
 - (e) activities, such as maintenance, where there is the potential for a high level of exposure;
 - (f) any relevant occupational exposure standard, maximum exposure limit or similar occupational exposure limit;
 - (g) the effect of preventive and control measures which have been or will be taken in accordance with regulation 7;
 - (h) the results of relevant health surveillance;
 - (i) the results of monitoring of exposure in accordance with regulation 10;
 - (j) in circumstances where the work will involve exposure to more than one substance hazardous to health, the risk presented by exposure to such substances in combination;
 - (k) the approved classification of any biological agent; and
 - (l) such additional information as the employer may need in order to complete the risk assessment.
- (3) The risk assessment shall be reviewed regularly and forthwith if—
- (a) there is reason to suspect that the risk assessment is no longer valid;
 - (b) there has been a significant change in the work to which the risk assessment relates; or
 - (c) the results of any monitoring carried out in accordance with regulation 10 show it to be necessary,
- and where, as a result of the review, changes to the risk assessment are required, those changes shall be made.
- (4) Where the employer employs 5 or more employees, he shall record—
- (a) the significant findings of the risk assessment as soon as is practicable after the risk assessment is made; and
 - (b) the steps which he has taken to meet the requirements of regulation 7.

Prevention or control of exposure to substances hazardous to health

7.—(1) Every employer shall ensure that the exposure of his employees to substances hazardous to health is either prevented or, where this is not reasonably practicable, adequately controlled.

(2) In complying with his duty of prevention under paragraph (1), substitution shall by preference be undertaken, whereby the employer shall avoid, so far as is reasonably practicable, the use of a substance hazardous to health at the workplace by replacing it with a substance or process which, under the conditions of its use, either eliminates or reduces the risk to the health of his employees.

(3) Where it is not reasonably practicable to prevent exposure to a substance hazardous to health, the employer shall comply with his duty of control under paragraph (1) by applying protection measures appropriate to the activity and consistent with the risk assessment, including, in order of priority—

- (a) the design and use of appropriate work processes, systems and engineering controls and the provision and use of suitable work equipment and materials;
 - (b) the control of exposure at source, including adequate ventilation systems and appropriate organisational measures; and
 - (c) where adequate control of exposure cannot be achieved by other means, the provision of suitable personal protective equipment in addition to the measures required by sub-paragraphs (a) and (b).
- (4) The measures referred to in paragraph (3) shall include—

- (a) arrangements for the safe handling, storage and transport of substances hazardous to health, and of waste containing such substances, at the workplace;
 - (b) the adoption of suitable maintenance procedures;
 - (c) reducing, to the minimum required for the work concerned—
 - (i) the number of employees subject to exposure,
 - (ii) the level and duration of exposure, and
 - (iii) the quantity of substances hazardous to health present at the workplace;
 - (d) the control of the working environment, including appropriate general ventilation; and
 - (e) appropriate hygiene measures including adequate washing facilities.
- (5) Without prejudice to the generality of paragraph (1), where it is not reasonably practicable to prevent exposure to a carcinogen, the employer shall apply the following measures in addition to those required by paragraph (3)—
- (a) totally enclosing the process and handling systems, unless this is not reasonably practicable;
 - (b) the prohibition of eating, drinking and smoking in areas that may be contaminated by carcinogens;
 - (c) cleaning floors, walls and other surfaces at regular intervals and whenever necessary;
 - (d) designating those areas and installations which may be contaminated by carcinogens and using suitable and sufficient warning signs; and
 - (e) storing, handling and disposing of carcinogens safely, including using closed and clearly labelled containers.
- (6) Without prejudice to the generality of paragraph (1), where it is not reasonably practicable to prevent exposure to a biological agent, the employer shall apply the following measures in addition to those required by paragraph (3)—
- (a) displaying suitable and sufficient warning signs, including the biohazard sign shown in Part IV of Schedule 3;
 - (b) specifying appropriate decontamination and disinfection procedures;
 - (c) instituting means for the safe collection, storage and disposal of contaminated waste, including the use of secure and identifiable containers, after suitable treatment where appropriate;
 - (d) testing, where it is necessary and technically possible, for the presence, outside the primary physical confinement, of biological agents used at work;
 - (e) specifying procedures for working with, and transporting at the workplace, a biological agent or material that may contain such an agent;
 - (f) where appropriate, making available effective vaccines for those employees who are not already immune to the biological agent to which they are exposed or are liable to be exposed;
 - (g) instituting hygiene measures compatible with the aim of preventing or reducing the accidental transfer or release of a biological agent from the workplace, including—
 - (i) the provision of appropriate and adequate washing and toilet facilities, and
 - (ii) where appropriate, the prohibition of eating, drinking, smoking and the application of cosmetics in working areas where there is a risk of contamination by biological agents; and
 - (h) where there are human patients or animals which are, or are suspected of being, infected with a Group 3 or 4 biological agent, the employer shall select the most suitable control and

containment measures from those listed in Part II of Schedule 3 with a view to controlling adequately the risk of infection.

(7) Without prejudice to the generality of paragraph (1), where there is exposure to a substance for which a maximum exposure limit has been approved, control of exposure shall, so far as the inhalation of that substance is concerned, only be treated as being adequate if the level of exposure is reduced so far as is reasonably practicable and in any case below the maximum exposure limit.

(8) Without prejudice to the generality of paragraph (1), where there is exposure to a substance for which an occupational exposure standard has been approved, control of exposure shall, so far as the inhalation of that substance is concerned, only be treated as being adequate if—

- (a) that occupational exposure standard is not exceeded; or
- (b) where that occupational exposure standard is exceeded, the employer identifies the reasons for the standard being exceeded and takes appropriate action to remedy the situation as soon as is reasonably practicable.

(9) Personal protective equipment provided by an employer in accordance with this regulation shall be suitable for the purpose and shall—

- (a) comply with any provision in the Personal Protective Equipment Regulations 2002⁽¹⁶⁾ which is applicable to that item of personal protective equipment; or
- (b) in the case of respiratory protective equipment, where no provision referred to in subparagraph (a) applies, be of a type approved or shall conform to a standard approved, in either case, by the Executive.

(10) Without prejudice to the provisions of this regulation, Schedule 3 shall have effect in relation to work with biological agents.

(11) In this regulation, “adequate” means adequate having regard only to the nature of the substance and the nature and degree of exposure to substances hazardous to health and “adequately” shall be construed accordingly.

Use of control measures etc.

8.—(1) Every employer who provides any control measure, other thing or facility in accordance with these Regulations shall take all reasonable steps to ensure that it is properly used or applied as the case may be.

(2) Every employee shall make full and proper use of any control measure, other thing or facility provided in accordance with these Regulations and, where relevant, shall—

- (a) take all reasonable steps to ensure it is returned after use to any accommodation provided for it; and
- (b) if he discovers a defect therein, report it forthwith to his employer.

Maintenance, examination and testing of control measures

9.—(1) Every employer who provides any control measure to meet the requirements of regulation 7 shall ensure that, where relevant, it is maintained in an efficient state, in efficient working order, in good repair and in a clean condition.

(2) Where engineering controls are provided to meet the requirements of regulation 7, the employer shall ensure that thorough examination and testing of those controls is carried out—

- (a) in the case of local exhaust ventilation plant, at least once every 14 months, or for local exhaust ventilation plant used in conjunction with a process specified in Column 1 of

(16) S.I. 2002/1144.

Schedule 4, at not more than the interval specified in the corresponding entry in Column 2 of that Schedule; or

(b) in any other case, at suitable intervals.

(3) Where respiratory protective equipment (other than disposable respiratory protective equipment) is provided to meet the requirements of regulation 7, the employer shall ensure that thorough examination and, where appropriate, testing of that equipment is carried out at suitable intervals.

(4) Every employer shall keep a suitable record of the examinations and tests carried out in accordance with paragraphs (2) and (3) and of repairs carried out as a result of those examinations and tests, and that record or a suitable summary thereof shall be kept available for at least 5 years from the date on which it was made.

(5) Every employer shall ensure that personal protective equipment, including protective clothing, is:

- (a) properly stored in a well-defined place;
- (b) checked at suitable intervals; and
- (c) when discovered to be defective, repaired or replaced before further use.

(6) Personal protective equipment which may be contaminated by a substance hazardous to health shall be removed on leaving the working area and kept apart from uncontaminated clothing and equipment.

(7) The employer shall ensure that the equipment referred to in paragraph (6) is subsequently decontaminated and cleaned or, if necessary, destroyed.

Monitoring exposure at the workplace

10.—(1) Where the risk assessment indicates that—

- (a) it is requisite for ensuring the maintenance of adequate control of the exposure of employees to substances hazardous to health; or
- (b) it is otherwise requisite for protecting the health of employees,

the employer shall ensure that the exposure of employees to substances hazardous to health is monitored in accordance with a suitable procedure.

(2) Paragraph (1) shall not apply where the employer is able to demonstrate by another method of evaluation that the requirements of regulation 7(1) have been complied with.

(3) The monitoring referred to in paragraph (1) shall take place—

- (a) at regular intervals; and
- (b) when any change occurs which may affect that exposure.

(4) Where a substance or process is specified in Column 1 of Schedule 5, monitoring shall be carried out at least at the frequency specified in the corresponding entry in Column 2 of that Schedule.

(5) The employer shall ensure that a suitable record of monitoring carried out for the purpose of this regulation is made and maintained and that that record or a suitable summary thereof is kept available—

- (a) where the record is representative of the personal exposures of identifiable employees, for at least 40 years; or
- (b) in any other case, for at least 5 years,

from the date of the last entry made in it.

(6) Where an employee is required by regulation 11 to be under health surveillance, an individual record of any monitoring carried out in accordance with this regulation shall be made, maintained and kept in respect of that employee.

(7) The employer shall—

- (a) on reasonable notice being given, allow an employee access to his personal monitoring record;
- (b) provide the Executive with copies of such monitoring records as the Executive may require; and
- (c) if he ceases to trade, notify the Executive forthwith in writing and make available to the Executive all monitoring records kept by him.

Health surveillance

11.—(1) Where it is appropriate for the protection of the health of his employees who are, or are liable to be, exposed to a substance hazardous to health, the employer shall ensure that such employees are under suitable health surveillance.

(2) Health surveillance shall be treated as being appropriate where—

- (a) the employee is exposed to one of the substances specified in Column 1 of Schedule 6 and is engaged in a process specified in Column 2 of that Schedule, and there is a reasonable likelihood that an identifiable disease or adverse health effect will result from that exposure; or
- (b) the exposure of the employee to a substance hazardous to health is such that—
 - (i) an identifiable disease or adverse health effect may be related to the exposure,
 - (ii) there is a reasonable likelihood that the disease or effect may occur under the particular conditions of his work, and
 - (iii) there are valid techniques for detecting indications of the disease or effect,and the technique of investigation is of low risk to the employee.

(3) The employer shall ensure that a health record, containing particulars approved by the Executive, in respect of each of his employees to whom paragraph (1) applies, is made and maintained and that that record or a copy thereof is kept available in a suitable form for at least 40 years from the date of the last entry made in it.

(4) The employer shall—

- (a) on reasonable notice being given, allow an employee access to his personal health record;
- (b) provide the Executive with copies of such health records as the Executive may require; and
- (c) if he ceases to trade, notify the Executive forthwith in writing and make available to the Executive all health records kept by him.

(5) If an employee is exposed to a substance specified in Schedule 6 and is engaged in a process specified therein, the health surveillance required under paragraph (1) shall include medical surveillance under the supervision of a relevant doctor at intervals of not more than 12 months or at such shorter intervals as the relevant doctor may require.

(6) Where an employee is subject to medical surveillance in accordance with paragraph (5) and a relevant doctor has certified by an entry in the health record of that employee that in his professional opinion that employee should not be engaged in work which exposes him to that substance or that he should only be so engaged under conditions specified in the record, the employer shall not permit the employee to be engaged in such work except in accordance with the conditions, if any, specified in the health record, unless that entry has been cancelled by a relevant doctor.

(7) Where an employee is subject to medical surveillance in accordance with paragraph (5) and a relevant doctor has certified by an entry in his health record that medical surveillance should be continued after his exposure to that substance has ceased, the employer shall ensure that the medical surveillance of that employee is continued in accordance with that entry while he is employed by the employer, unless that entry has been cancelled by a relevant doctor.

(8) An employee to whom this regulation applies shall, when required by his employer and at the cost of the employer, present himself during his working hours for such health surveillance procedures as may be required for the purposes of paragraph (1) and, in the case of an employee who is subject to medical surveillance in accordance with paragraph (5), shall furnish the relevant doctor with such information concerning his health as the relevant doctor may reasonably require.

(9) Where, as a result of health surveillance, an employee is found to have an identifiable disease or adverse health effect which is considered by a relevant doctor or other occupational health professional to be the result of exposure to a substance hazardous to health the employer of that employee shall—

- (a) ensure that a suitably qualified person informs the employee accordingly and provides the employee with information and advice regarding further health surveillance;
- (b) review the risk assessment;
- (c) review any measure taken to comply with regulation 7, taking into account any advice given by a relevant doctor, occupational health professional or by the Executive;
- (d) consider assigning the employee to alternative work where there is no risk of further exposure to that substance, taking into account any advice given by a relevant doctor or occupational health professional; and
- (e) provide for a review of the health of any other employee who has been similarly exposed, including a medical examination where such an examination is recommended by a relevant doctor, occupational health professional or by the Executive.

(10) Where, for the purpose of carrying out his functions under these Regulations, a relevant doctor requires to inspect any workplace or any record kept for the purposes of these Regulations, the employer shall permit him to do so.

(11) Where an employee or an employer is aggrieved by a decision recorded in the health record by a relevant doctor to suspend an employee from work which exposes him to a substance hazardous to health (or to impose conditions on such work), he may, by an application in writing to the Executive within 28 days of the date on which he was notified of the decision, apply for that decision to be reviewed in accordance with a procedure approved for the purposes of this paragraph by the Health and Safety Commission, and the result of that review shall be notified to the employee and employer and entered in the health record in accordance with the approved procedure.

Information, instruction and training for persons who may be exposed to substances hazardous to health

12.—(1) Every employer who undertakes work which is liable to expose an employee to a substance hazardous to health shall provide that employee with suitable and sufficient information, instruction and training.

(2) Without prejudice to the generality of paragraph (1), the information, instruction and training provided under that paragraph shall include—

- (a) details of the substances hazardous to health to which the employee is liable to be exposed including—
 - (i) the names of those substances and the risk which they present to health,
 - (ii) any relevant occupational exposure standard, maximum exposure limit or similar occupational exposure limit,

- (iii) access to any relevant safety data sheet, and
- (iv) other legislative provisions which concern the hazardous properties of those substances;
- (b) the significant findings of the risk assessment;
- (c) the appropriate precautions and actions to be taken by the employee in order to safeguard himself and other employees at the workplace;
- (d) the results of any monitoring of exposure in accordance with regulation 10 and, in particular, in the case of a substance hazardous to health for which a maximum exposure limit has been approved, the employee or his representatives shall be informed forthwith, if the results of such monitoring show that the maximum exposure limit has been exceeded;
- (e) the collective results of any health surveillance undertaken in accordance with regulation 11 in a form calculated to prevent those results from being identified as relating to a particular person; and
- (f) where employees are working with a Group 4 biological agent or material that may contain such an agent, the provision of written instructions and, if appropriate, the display of notices which outline the procedures for handling such an agent or material.
- (3) The information, instruction and training required by paragraph (1) shall be—
 - (a) adapted to take account of significant changes in the type of work carried out or methods of work used by the employer; and
 - (b) provided in a manner appropriate to the level, type and duration of exposure identified by the risk assessment.
- (4) Every employer shall ensure that any person (whether or not his employee) who carries out work in connection with the employer's duties under these Regulations has suitable and sufficient information, instruction and training.
- (5) Where containers and pipes for substances hazardous to health used at work are not marked in accordance with any relevant legislation listed in Schedule 7, the employer shall, without prejudice to any derogations provided for in that legislation, ensure that the contents of those containers and pipes, together with the nature of those contents and any associated hazards, are clearly identifiable.

Arrangements to deal with accidents, incidents and emergencies

- 13.—**(1) Subject to paragraph (4) and without prejudice to the relevant provisions of the Management of Health and Safety at Work Regulations 1999⁽¹⁷⁾, in order to protect the health of his employees from an accident, incident or emergency related to the presence of a substance hazardous to health at the workplace, the employer shall ensure that—
- (a) procedures, including the provision of appropriate first-aid facilities and relevant safety drills (which shall be tested at regular intervals), have been prepared which can be put into effect when such an event occurs;
 - (b) information on emergency arrangements, including—
 - (i) details of relevant work hazards and hazard identification arrangements, and
 - (ii) specific hazards likely to arise at the time of an accident, incident or emergency, is available; and
 - (c) suitable warning and other communication systems are established to enable an appropriate response, including remedial actions and rescue operations, to be made immediately when such an event occurs.

⁽¹⁷⁾ S.I. 1999/3242.

(2) The employer shall ensure that information on the procedures and systems required by paragraph (1)(a) and (c) and the information required by paragraph(1)(b) is—

- (a) made available to relevant accident and emergency services to enable those services, whether internal or external to the workplace, to prepare their own response procedures and precautionary measures; and
- (b) displayed at the workplace, if this is appropriate.

(3) Subject to paragraph (4), in the event of an accident, incident or emergency related to the presence of a substance hazardous to health at the workplace, the employer shall ensure that—

- (a) immediate steps are taken to—
 - (i) mitigate the effects of the event,
 - (ii) restore the situation to normal, and
 - (iii) inform those of his employees who may be affected;
- (b) only those persons who are essential for the carrying out of repairs and other necessary work are permitted in the affected area and they are provided with—
 - (i) appropriate personal protective equipment, and
 - (ii) any necessary specialised safety equipment and plant,
 which shall be used until the situation is restored to normal; and
- (c) in the case of an incident or accident which has or may have resulted in the release of a biological agent which could cause severe human disease, as soon as practicable thereafter his employees or their representatives are informed of—
 - (i) the causes of that incident or accident, and
 - (ii) the measures taken or to be taken to rectify the situation.

(4) Paragraph (1) and, provided the substance hazardous to health is not a carcinogen or biological agent, paragraph (3) shall not apply where—

- (a) the results of the risk assessment show that, because of the quantity of each substance hazardous to health present at the workplace, there is only a slight risk to the health of employees; and
- (b) the measures taken by the employer to comply with the duty under regulation 7(1) are sufficient to control that risk.

(5) An employee shall report forthwith, to his employer or to any other employee of that employer with specific responsibility for the health and safety of his fellow employees, any accident or incident which has or may have resulted in the release of a biological agent which could cause severe human disease.

Provisions relating to certain fumigations

14.—(1) This regulation shall apply to fumigations in which the fumigant used or intended to be used is hydrogen cyanide, phosphine or methyl bromide, except that paragraph (2) shall not apply to fumigations using the fumigant specified in Column 1 of Schedule 8 when the nature of the fumigation is that specified in the corresponding entry in Column 2 of that Schedule.

(2) An employer shall not undertake fumigation to which this regulation applies unless he has—

- (a) notified the persons specified in Part I of Schedule 9 of his intention to undertake the fumigation; and
- (b) provided to those persons the information specified in Part II of that Schedule,

at least 24 hours in advance, or such shorter time in advance as the persons required to be notified may agree.

(3) An employer who undertakes a fumigation to which this regulation applies shall ensure that, before the fumigant is released, suitable warning notices have been affixed at all points of reasonable access to the premises or to those parts of the premises in which the fumigation is to be carried out and that after the fumigation has been completed, and the premises are safe to enter, those warning notices are removed.

Exemption certificates

15.—(1) Subject to paragraph (2) the Executive may, by a certificate in writing, exempt any person or class of persons or any substance or class of substances from all or any of the requirements or prohibitions imposed by regulations 4 (to the extent permitted by article 9 of Council Directive [98/24/EC](#)), 8, 9, 11(8), (10) and (11) and 14 of these Regulations and any such exemption may be granted subject to conditions and to a limit of time and may be revoked by a certificate in writing at any time.

(2) The Executive shall not grant any such exemption unless having regard to the circumstances of the case and, in particular, to—

- (a) the conditions, if any, which it proposes to attach to the exemption; and
- (b) any requirements imposed by or under any enactments which apply to the case,

it is satisfied that the health and safety of persons who are likely to be affected by the exemption will not be prejudiced in consequence of it.

Exemptions relating to the Ministry of Defence etc.

16.—(1) In this regulation—

- (a) “Her Majesty’s Forces” means any of the naval, military or air forces of the Crown, whether raised inside or outside the United Kingdom and whether any such force is a regular, auxiliary or reserve force, and includes any civilian employed by those forces;
- (b) “visiting force” has the same meaning as it does for the purposes of any provision of Part I of the Visiting Forces Act 1952⁽¹⁸⁾; and
- (c) “headquarters” means a headquarters for the time being specified in Schedule 2 to the Visiting Forces and International Headquarters (Application of Law) Order 1999⁽¹⁹⁾.

(2) The Secretary of State for Defence may, in the interests of national security, by a certificate in writing exempt—

- (a) any of Her Majesty’s Forces;
- (b) any visiting force;
- (c) members of a visiting force working in or attached to a headquarters; or
- (d) any person engaged in work involving substances hazardous to health, if that person is under the direct supervision of a representative of the Secretary of State for Defence,

from all or any of the requirements or prohibitions imposed by these Regulations and any such exemption may be granted subject to conditions and to a limit of time and may be revoked at any time by a certificate in writing, except that, where any such exemption is granted, suitable arrangements shall be made for the assessment of the health risk created by the work involving substances hazardous to health and for adequately controlling the exposure to those substances of persons to whom the exemption relates.

(3) Regulation 11(11) shall not apply in relation to—

⁽¹⁸⁾ 1952 c. 67.

⁽¹⁹⁾ S.I. 1999/1736.

- (a) any visiting force; or
- (b) members of a visiting force working in or attached to a headquarters.

Extension outside Great Britain

17.—(1) Subject to paragraph (2), these Regulations shall apply to and in relation to any activity outside Great Britain to which sections 1 to 59 and 80 to 82 of the 1974 Act apply by virtue of the Health and Safety at Work etc. Act 1974 (Application outside Great Britain) Order 2001⁽²⁰⁾ as those provisions apply within Great Britain.

(2) These Regulations shall not extend to Northern Ireland except insofar as they relate to imports of substances and articles referred to in regulation 4(2) into the United Kingdom.

Revocation and savings

18.—(1) The Control of Substances Hazardous to Health Regulations 1999⁽²¹⁾ are revoked.

(2) Any record or register required to be kept under the Regulations revoked by paragraph (1) shall, notwithstanding that revocation, be kept in the same manner and for the same period as specified in those Regulations as if these Regulations had not been made, except that the Executive may approve the keeping of records at a place or in a form other than at the place where, or in the form in which, records were required to be kept under the Regulations so revoked.

Extension of meaning of “work”

19. For the purposes of Part I of the 1974 Act the meaning of “work” shall be extended to include any activity involving the consignment, storage or use of a Group 2, 3 or 4 biological agent and the meaning of “at work” shall be extended accordingly, and in that connection the references to employer in paragraphs 5 and 6 of Schedule 3 include references to any persons carrying out such an activity.

Modification of section 3(2) of the 1974 Act

20. Section 3(2) of the 1974 Act shall be modified in relation to an activity involving the consignment, storage or use of any of the biological agents referred to in regulation 19 so as to have effect as if the reference therein to a self-employed person is a reference to any person who is not an employer or an employee and the reference therein to his undertaking includes a reference to such an activity.

Defence

21. Subject to regulation 21 of the Management of Health and Safety at Work Regulations 1999⁽²²⁾, in any proceedings for an offence consisting of a contravention of these Regulations it shall be a defence for any person to prove that he took all reasonable precautions and exercised all due diligence to avoid the commission of that offence.

⁽²⁰⁾ [S.I. 2001/2127](#).

⁽²¹⁾ [S.I. 1999/437](#).

⁽²²⁾ [S.I. 1999/3242](#).

Signed by authority of the Secretary of State.

N. Brown
Minister of State,
Department for Work and Pensions

SCHEDULE 1

Regulation 2(1)

OTHER SUBSTANCES AND PROCESSES TO WHICH
THE DEFINITION OF “CARCINOGEN” RELATES

Aflatoxins.

Arsenic.

Auramine manufacture.

Calcining, sintering or smelting of nickel copper matte or acid leaching or electrorefining of roasted matte.

Coal soots, coal tar, pitch and coal tar fumes.

Hardwood dusts.

Isopropyl alcohol manufacture (strong acid process).

Leather dust in boot and shoe manufacture, arising during preparation and finishing.

Magenta manufacture.

Mustard gas (β , β' –dichlorodiethyl sulphide).

Rubber manufacturing and processing giving rise to rubber process dust and rubber fume.

Used engine oils.

SCHEDULE 2

Regulation 4(1)

PROHIBITION OF CERTAIN SUBSTANCES
HAZARDOUS TO HEALTH FOR CERTAIN PURPOSES

Column 1 <i>Description of substance</i>	Column 2 <i>Purpose for which the substance is prohibited</i>
1. 2-naphthylamine; benzidine; 4-aminodiphenyl; 4-nitrodiphenyl; their salts and any substance containing any of those compounds, in a total concentration equal to or greater than 0.1 per cent by mass.	Manufacture and use for all purposes including any manufacturing process in which a substance described in Column 1 of this item is formed.
2. Sand or other substance containing free silica.	Use as an abrasive for blasting articles in any blasting apparatus.
3. A substance— (a) containing compounds of silicon calculated as silica to the extent of more than 3 per cent by weight of dry	Use as a parting material in connection with the making of metal castings.

Status: This is the original version (as it was originally made).

Column 1 <i>Description of substance</i>	Column 2 <i>Purpose for which the substance is prohibited</i>
(b) material, other than natural sand, zirconium silicate (zircon), calcined china clay, calcined aluminous fireclay, sillimanite, calcined or fused alumina, olivine; or composed of or containing dust or other matter deposited from a fettling or blasting process.	
4. Carbon disulphide.	Use in the cold-cure process of vulcanising in the proofing of cloth with rubber.
5. Oils other than white oil, or oil of entirely animal or vegetable origin or entirely of mixed animal and vegetable origin.	Use for oiling the spindles of self-acting mules.
6. Ground or powdered flint or quartz other than natural sand.	Use in relation to the manufacture or decoration of pottery for the following purposes: (a) the placing of ware for the biscuit fire; (b) the polishing of ware; (c) as the ingredient of a wash for saggars, trucks, bats, cranks, or other articles used in supporting ware during firing; and (d) as dusting or supporting powder in potters' shops.
7. Ground or powdered flint or quartz other than— (a) natural sand; or (b) ground or powdered flint or quartz which forms parts of a slop or paste.	Use in relation to the manufacture or decoration of pottery for any purpose except— (a) use in a separate room or building for— (i) the manufacture of powdered flint or quartz, or (ii) the making of frits or glazes or the making of colours or coloured slips

Column 1	<i>Description of substance</i>	Column 2	<i>Purpose for which the substance is prohibited</i>
			for the decoration of pottery;
		(b)	use for the incorporation of the substance into the body of ware in an enclosure in which no person is employed and which is constructed and ventilated to prevent the escape of dust.
8.	Dust or powder of a refractory material containing not less than 80 per cent of silica other than natural sand.		Use for sprinkling the moulds of silica bricks, namely bricks or other articles composed of refractory material and containing not less than 80 per cent of silica.
9.	White phosphorus.		Use in the manufacture of matches.
10.	Hydrogen cyanide.		Use in fumigation except when—
		(a)	released from an inert material in which hydrogen cyanide is absorbed;
		(b)	generated from a gassing powder; or
		(c)	applied from a cylinder through suitable piping and applicators other than for fumigation in the open air to control or kill mammal pests.
11.	Benzene and any substance containing benzene in a concentration equal to or greater than 0.1 per cent by mass, other than—		Use for all purposes except—
	(a) motor fuels covered by Council Directive 85/210/EEC (OJ No. L96, 3.4.85, p. 25);	(a)	use in industrial processes; and
	(b) waste covered by Council Directives 75/442/EEC (OJ No. L194, 25.7.75, p. 39), as amended by Council Directive 91/156/EEC (OJ	(b)	for the purposes of research and development or for the purpose of analysis.

Status: This is the original version (as it was originally made).

Column 1 <i>Description of substance</i>	Column 2 <i>Purpose for which the substance is prohibited</i>
	No. L78, 26.3.91, p. 32), and 91/689/EEC (OJ No. L377, 31.12.91, p. 20).
12.	The following substances— Chloroform CAS No. 67-66-3; Carbon Tetrachloride CAS No. 56-23-5; 1,1,2 Trichloroethane CAS No. 79-00-5; 1,1,2,2 Tetrachloroethane CAS No. 79-34-5; 1,1,1,2 Tetrachloroethane CAS No. 630-20-6; Pentachloroethane CAS No. 76-01-7; Vinylidene chloride (1,1 Dichloroethylene) CAS No. 75-35-4; 1,1,1 Trichloroethane CAS No. 71-55-6, and any substance containing one or more of those substances in a concentration equal to or greater than 0.1 per cent by mass, other than— (a) medicinal products; (b) cosmetic products.

In this Schedule—

“aerosol dispenser” means an article which consists of a non-reusable receptacle containing a gas compressed, liquefied or dissolved under pressure, with or without liquid, paste or powder and fitted with a release device allowing the contents to be ejected as solid or liquid particles in suspension in a gas, as a foam, paste or powder or in a liquid state;

“blasting apparatus” means apparatus for cleaning, smoothing, roughening or removing of part of the surface of any article by the use as an abrasive of a jet of sand, metal shot or grit or other material propelled by a blast of compressed air or steam or by a wheel;

“CASNo. ” is the number assigned to a substance by the Chemical Abstract Service;

“cosmetic product” has the meaning assigned to it in regulation 2(1) of the Cosmetic Products (Safety) Regulations 1996(23) (including any aerosol dispenser containing a cosmetic product);

“gassing powder” means a chemical compound in powder form which reacts with atmospheric moisture to generate hydrogen cyanide;

“medicinal product” means a substance or preparation which is—

(a) intended for use as a medicinal product within the meaning of section 130 of the Medicines Act 1968(24); or

(b) a substance or preparation specified in an order made under section 104 or 105 of the Medicines Act 1968 which is for the time being in force and which directs that specified provisions of that Act shall have effect in relation to that substance or preparation as such provisions have effect in relation to medicinal products within the meaning of that Act;

(23) S.I. 1996/2925.

(24) 1968 c. 67.

“use as a parting material” means the application of the material to the surface or parts of the surface of a pattern or of a mould so as to facilitate the separation of the pattern from the mould or the separation of parts of the mould;
 “white oil” means a refined mineral oil conforming to a specification approved by the Executive and certified by its manufacturer as so conforming.

SCHEDULE 3

Regulation 7(10)

ADDITIONAL PROVISIONS RELATING TO WORK WITH BIOLOGICAL AGENTS

PART I

PROVISIONS OF GENERAL APPLICATION TO BIOLOGICAL AGENTS

Interpretation

1. In this Schedule “diagnostic service” means any activity undertaken solely with the intention of analysing specimens or samples from a human patient or animal in which a biological agent is or is suspected of being present for purposes relating to the assessment of the clinical progress, or assistance in the clinical management, of that patient or animal, and “diagnosis” shall be construed accordingly.

Classification of biological agents

2.—(1) Where a biological agent does not have an approved classification, the employer shall provisionally classify that agent in accordance with sub-paragraph (2), having regard to the nature of the agent and the properties of which he may reasonably be expected to be aware.

(2) When provisionally classifying a biological agent the employer shall assign that agent to one of the following Groups according to its level of risk of infection and, if in doubt as to which of two alternative Groups is the most appropriate, he shall assign it to the higher of the two—

- (a) Group 1—unlikely to cause human disease;
- (b) Group 2—can cause human disease and may be a hazard to employees; it is unlikely to spread to the community and there is usually effective prophylaxis or treatment available;
- (c) Group 3—can cause severe human disease and may be a serious hazard to employees; it may spread to the community, but there is usually effective prophylaxis or treatment available;
- (d) Group 4—causes severe human disease and is a serious hazard to employees; it is likely to spread to the community and there is usually no effective prophylaxis or treatment available.

(3) Where an employer is using a biological agent which has an approved classification and the risk of infection for that particular agent is different to that expected, the employer shall reclassify the agent in consultation with the Executive as if performing a provisional classification under sub-paragraph (2).

Special control measures for laboratories, animal rooms and industrial processes

3.—(1) Every employer who is engaged in any of the activities specified in sub-paragraph (3) shall ensure that measures taken to control adequately the exposure of his employees to biological

agents include, in particular, the most suitable combination of containment measures from those listed in Parts II and III of this Schedule as appropriate, taking into account—

- (a) the nature of the activity specified in sub-paragraph (3);
 - (b) the minimum containment level specified in sub-paragraph (4);
 - (c) the risk assessment; and
 - (d) the nature of the biological agent concerned.
- (2) An employer who is engaged in—
- (a) any of the activities specified in sub-paragraph (3)(a) or (b) shall select measures from Part II of this Schedule;
 - (b) the activity specified in sub-paragraph (3)(c) shall select measures from Part III of this Schedule and, subject to sub-paragraph (4), when making that selection he may combine measures from different containment levels on the basis of a risk assessment related to any particular process or part of a process.
- (3) The activities referred to in sub-paragraph (1) are—
- (a) research, development, teaching or diagnostic work in laboratories which involves working with a Group 2, Group 3 or Group 4 biological agent or material containing such an agent;
 - (b) working with animals which have been deliberately infected with a Group 2, Group 3 or Group 4 biological agent or which are, or are suspected of being, naturally infected with such an agent; and
 - (c) industrial processes which involve working with a Group 2, Group 3 or Group 4 biological agent.
- (4) Subject to sub-paragraph (5), the minimum containment level referred to in sub-paragraph (1) shall be—
- (a) level 2 for activities which involve working with a Group 2 biological agent;
 - (b) level 3 for activities which involve working with a Group 3 biological agent;
 - (c) level 4 for activities which involve working with a Group 4 biological agent;
 - (d) level 2 for laboratories which do not intentionally propagate, concentrate or otherwise increase the risk of exposure to a biological agent but work with materials in respect of which it is unlikely that a Group 3 or Group 4 biological agent is present;
 - (e) level 3 or 4, where appropriate, for laboratories which do not intentionally propagate, concentrate or otherwise increase the risk of exposure to a Group 3 or Group 4 biological agent but where the employer knows, or it is likely, that such a containment level is necessary; and
 - (f) level 3 for activities where it has not been possible to carry out a conclusive assessment but where there is concern that the activity might involve a serious health risk for employees.
- (5) The Health and Safety Commission may approve guidelines specifying the minimum containment measures which are to apply in any particular case.
- (6) The Health and Safety Commission shall not approve any guidelines under paragraph (5) unless it is satisfied that the health of any person who is likely to be affected by the use of those guidelines will not be prejudiced.

List of employees exposed to certain biological agents

4.—(1) Subject to sub-paragraph (2), every employer shall keep a list of employees exposed to a Group 3 or Group 4 biological agent, indicating the type of work done and, where known, the

biological agent to which they have been exposed, and records of exposures, accidents and incidents, as appropriate.

(2) Sub-paragraph (1) shall not apply where the results of the risk assessment indicate that—

- (a) the activity does not involve a deliberate intention to work with or use that biological agent; and
- (b) there is no significant risk to the health of employees associated with that biological agent.

(3) The employer shall ensure that the list or a copy thereof is kept available in a suitable form for at least 40 years from the date of the last entry made in it.

(4) The relevant doctor referred to in regulation 11, and any employee of that employer with specific responsibility for the health and safety of his fellow employees, shall have access to the list.

(5) Each employee shall have access to the information on the list which relates to him personally.

Notification of the use of biological agents

5.—(1) Subject to sub-paragraphs (7) and (8), an employer shall not use for the first time one or more biological agents in Group 2, 3 or 4 at particular premises for any of the activities listed in paragraph 3(3) unless he has—

- (a) notified the Executive in writing of his intention to do so at least 20 working days in advance, or such shorter period as the Executive may allow;
- (b) furnished with that notification the particulars specified in sub-paragraph (5); and
- (c) received the acknowledgement required by sub-paragraph (4).

(2) Subject to sub-paragraphs (7) and (9), an employer shall not use a biological agent which is specified in Part V of this Schedule, except where the use of that agent has been notified to the Executive in accordance with sub-paragraph (1), for any of the activities listed in paragraph 3(3) unless he has—

- (a) notified the Executive in writing of his intention to do so at least 20 working days in advance, or such shorter period as the Executive may allow;
- (b) furnished with that notification the particulars specified in sub-paragraph (5); and
- (c) received the acknowledgement required by sub-paragraph (4).

(3) The Executive may accept a single notification under sub-paragraph (2) in respect of the use of more than one biological agent by the same person.

(4) Upon receipt of the notification required by sub-paragraph (1) or (2), the Executive shall, within 20 working days—

- (a) send to the notifier an acknowledgement of receipt; or
- (b) if the notification does not contain all of the particulars specified in sub-paragraph (5)—
 - (i) inform the notifier in writing of the further particulars required, and
 - (ii) within 10 working days of receipt of those further particulars, send to the notifier an acknowledgement of receipt.

(5) The particulars to be included in the notification referred to in sub-paragraphs (1) and (2) shall be—

- (a) the name and address of the employer and the address of the premises where the biological agent will be stored or used;
- (b) the name, qualifications and relevant experience of any employee of that employer with specific responsibility for the health and safety of his fellow employees;
- (c) the results of the risk assessment;

- (d) the identity of the biological agent and, if the agent does not have an approved classification, the Group to which the agent has been assigned; and
 - (e) the preventive and protective measures that are to be taken.
- (6) Where there are changes to processes, procedures or the biological agent which are of importance to health or safety at work and which render the original notification invalid the employer shall notify the Executive forthwith in writing of those changes.
- (7) Sub-paragraphs (1) and (2) shall not apply in relation to a biological agent where an intention to use that biological agent has been previously notified to the Executive in accordance with the Genetically Modified Organisms (Contained Use) Regulations 2000⁽²⁵⁾.
- (8) The requirement in sub-paragraph (1) to notify first use of a biological agent in Group 2 or 3 shall not apply to an employer whose only use of that agent is in relation to the provision of a diagnostic service provided that use will not involve a process likely to propagate, concentrate or otherwise increase the risk of exposure to that agent.
- (9) The requirement in sub-paragraph (2) to notify use of a biological agent specified in Part V of this Schedule shall not apply to an employer whose only use of that agent is in relation to the provision of a diagnostic service provided that use will not involve a process likely to propagate, concentrate or otherwise increase the risk of exposure to that agent.

Notification of the consignment of biological agents

- 6.—(1) An employer shall not consign a Group 4 biological agent or anything containing, or suspected of containing, such an agent to any other premises, whether or not those premises are under his ownership or control, unless he has notified the Executive in writing of his intention to do so at least 30 days in advance or before such shorter time as the Executive may approve and with that notification has furnished the particulars specified in sub-paragraph (4).
- (2) Sub-paragraph (1) shall not apply where—
- (a) the biological agent or material containing or suspected of containing such an agent is being consigned solely for the purpose of diagnosis;
 - (b) material containing or suspected of containing the biological agent is being consigned solely for the purpose of disposal; or
 - (c) the biological agent is or is suspected of being present in a human patient or animal which is being transported for the purpose of medical treatment.
- (3) Where a Group 4 biological agent is imported into Great Britain, the consignee shall give the notice required by sub-paragraph (1).
- (4) The particulars to be included in the notification referred to in sub-paragraph (1) shall be—
- (a) the identity of the biological agent and the volume of the consignment;
 - (b) the name of the consignor;
 - (c) the address of the premises from which it will be transported;
 - (d) the name of the consignee;
 - (e) the address of the premises to which it shall be transported;
 - (f) the name of the transport operator responsible for the transportation;
 - (g) the name of any individual who will accompany the consignment;
 - (h) the method of transportation;
 - (i) the packaging and any containment precautions which will be taken;

(25) [S.I. 2000/2831](#).

- (j) the route which will be taken; and
 (k) the proposed date of transportation.

PART II

CONTAINMENT MEASURES FOR HEALTH AND VETERINARY CARE FACILITIES, LABORATORIES AND ANIMAL ROOMS

<i>Containment measures</i>		<i>Containment levels</i>		
		2	3	4
1	The workplace is to be separated from any other activities in the same building.	No	Yes	Yes
2	Input air and extract air to the workplace are to be filtered using HEPA or equivalent.	No	Yes, on extract air	Yes, on input and double on extract air
3	Access is to be restricted to authorised persons only.	Yes	Yes	Yes, via air-lock key procedure
4	The workplace is to be sealable to permit disinfection.	No	Yes	Yes
5	Specified disinfection procedure.	Yes	Yes	Yes
6	The workplace is to be maintained at an air pressure negative to atmosphere.	No	Yes	Yes
7	Efficient vector control eg rodents and insects.	Yes, for animal containment	Yes, for animal containment	Yes
8	Surfaces impervious to water and easy to clean.	Yes, for bench	Yes, for bench and floor (and walls for animal containment)	Yes, for bench, floor, walls and ceiling
9	Surfaces resistant to acids, alkalis,	Yes, for bench	Yes, for bench and floor (and	Yes, for bench, floor, walls and ceiling

Status: This is the original version (as it was originally made).

<i>Containment measures</i>		<i>Containment levels</i>		
		2	3	4
	solvents, disinfectants.		walls for animal containment)	
10	Safe storage of biological agents.	Yes	Yes	Yes, secure storage
11	An observation window, or alternative, is to be present, so that occupants can be seen.	No	Yes	Yes
12	A laboratory is to contain its own equipment.	No	Yes, so far as is reasonably practicable	Yes
13	Infected material, including any animal, is to be handled in a safety cabinet or isolator or other suitable containment.	Yes, where aerosol produced	Yes, where aerosol produced	Yes
14	Incinerator for disposal of animal carcasses.	Accessible	Accessible	Yes, on site

PART III

CONTAINMENT MEASURES FOR INDUSTRIAL PROCESSES

<i>Containment measures</i>		<i>Containment levels</i>		
		2	3	4
1	Viable micro-organisms should be contained in a system which physically separates the process from the environment (closed system).	Yes	Yes	Yes
2	Exhaust gases from the closed system should be treated so as to—	Minimise release	Prevent release	Prevent release

Containment measures		Containment levels		
		2	3	4
3	Sample collection, addition of materials to a closed system and transfer of viable micro-organisms to another closed system, should be performed so as to—	Minimise release	Prevent release	Prevent release
4	Bulk culture fluids should not be removed from the closed system unless the viable micro-organisms have been—	Inactivated by validated means	Inactivated by validated chemical or physical means	Inactivated by validated chemical or physical means
5	Seals should be designed so as to—	Minimise release	Prevent release	Prevent release
6	Closed systems should be located within a controlled area—	Optional	Optional	Yes, and purpose-built
	(a) biohazard signs should be posted;	Optional	Yes	Yes
	(b) access should be restricted to nominated personnel only;	Optional	Yes	Yes, via air-lock
	(c) personnel should wear protective clothing;	Yes, work clothing	Yes	Yes, a complete change
	(d) decontamination and washing facilities	Yes	Yes	Yes

Status: This is the original version (as it was originally made).

Containment measures	Containment levels		
	2	3	4
should be provided for personnel;			
(e) personnel should shower before leaving the controlled area;	No	Optional	Yes
(f) effluent from sinks and showers should be collected and inactivated before release;	No	Optional	Yes
(g) the controlled area should be adequately ventilated to minimise air contamination;	Optional	Optional	Yes
(h) the controlled area should be maintained at an air pressure negative to atmosphere;	No	Optional	Yes

Containment measures		Containment levels		
		2	3	4
	(i) (i)put and extract air to the controlled area should be HEPA filtered;	No	Optional	Yes
	(j) (j)the controlled area should be designed to contain spillage of the entire contents of closed system;	Optional	Yes	Yes
	(k) (k)the controlled area should be sealable to permit fumigation.	No	Optional	Yes
7	Effluent treatment before final discharge.	Inactivated by validated means	Inactivated by validated chemical or physical means	Inactivated by validated physical means

PART IV

BIOHAZARD SIGN

The biohazard sign required by regulation 7(6)(a) shall be in the form shown below—

Status: This is the original version (as it was originally made).

PART V

BIOLOGICAL AGENTS WHOSE USE IS TO BE NOTIFIED IN ACCORDANCE WITH PARAGRAPH 5(2) OF PART I OF THIS SCHEDULE

Any Group 3 or 4 agent.

The following Group 2 agents:

Bordetella pertussis

Corynebacterium diphtheriae

Neisseria meningitidis

SCHEDULE 4

Regulation 9(2)(a)

FREQUENCY OF THOROUGH EXAMINATION AND TEST OF LOCAL EXHAUST VENTILATION PLANT USED IN CERTAIN PROCESSES

Column 1 <i>Process</i>	Column 2 <i>Minimum frequency</i>
Processes in which blasting is carried out in or incidental to the cleaning of metal castings, in connection with their manufacture.	1 month
Processes, other than wet processes, in which metal articles (other than of gold, platinum or iridium) are ground, abraded or polished using mechanical power, in any room for more than 12 hours in any week.	6 months
Processes giving off dust or fume in which non-ferrous metal castings are produced.	6 months
Jute cloth manufacture.	1 month

SCHEDULE 5

Regulation 10(4)

SPECIFIC SUBSTANCES AND PROCESSES FOR WHICH MONITORING IS REQUIRED

Column 1 <i>Substance or process</i>	Column 2 <i>Minimum frequency</i>
Vinyl chloride monomer.	Continuous or in accordance with a procedure approved by the Health and Safety Commission.
Spray given off from vessels at which an electrolytic chromium process is carried on, except trivalent chromium.	Every 14 days while the process is being carried on.

SCHEDULE 6

Regulation 11(2)(a) and (5)

MEDICAL SURVEILLANCE

Column 1 <i>Substances for which medical surveillance is appropriate</i>	Column 2 <i>Process</i>
Vinyl chloride monomer (VCM).	In manufacture, production, reclamation, storage, discharge, transport, use or polymerisation.
Nitro or amino derivatives of phenol and of benzene or its homologues.	In the manufacture of nitro or amino derivatives of phenol and of benzene or its homologues and the making of explosives with the use of any of these substances.
Potassium or sodium chromate or dichromate.	In manufacture.
Ortho-tolidine and its salts. Dianisidine and its salts. Dichlorobenzidine and its salts.	In manufacture, formation or use of these substances.
Auramine. Magenta.	In manufacture.
Carbon disulphide. Disulphur dichloride. Benzene, including benzol. Carbon tetrachloride. Trichlorethylene.	Processes in which these substances are used, or given off as vapour, in the manufacture of indiarubber or of articles or goods made wholly or partially of indiarubber.
Pitch.	In manufacture of blocks of fuel consisting of coal, coal dust, coke or slurry with pitch as a binding substance.

Status: This is the original version (as it was originally made).

SCHEDULE 7

Regulation 12(5)

LEGISLATION CONCERNED WITH THE LABELLING OF CONTAINERS AND PIPES

The Chemicals (Hazard Information and Packaging for Supply) Regulations 2002 (CHIP) ([SI 2002/1689](#));

The Health and Safety (Safety Signs and Signals) Regulations 1996 ([SI 1996/341](#));

The Radioactive Material (Road Transport) Regulations 2002 ([SI 2002/1093](#));

The Carriage of Dangerous Goods by Rail Regulations 1996 ([SI 1996/2089](#));

The Packaging, Labelling and Carriage of Radioactive Material by Rail Regulations 2002 ([SI 2002/2099](#));

The Carriage of Dangerous Goods (Classification, Packaging and Labelling) and Use of Transportable Pressure Receptacles Regulations 1996 ([SI 1996/2092](#));

The Carriage of Explosives by Road Regulations 1996 ([SI 1996/2093](#));

The Carriage of Dangerous Goods by Road Regulations 1996 ([SI 1996/2095](#)); and

The Good Laboratory Practice Regulations 1999 ([SI 1999/3106](#)).

SCHEDULE 8

Regulation 14(1)

FUMIGATIONS EXCEPTED FROM REGULATION 14

Column 1 <i>Fumigant</i>	Column 2 <i>Nature of fumigation</i>
Hydrogen cyanide.	Fumigations carried out for research. Fumigations in fumigation chambers. Fumigations in the open air to control or kill mammal pests.
Methyl bromide.	Fumigations carried out for research. Fumigations in fumigation chambers. Fumigations of soil outdoors under gas-proof sheeting where not more than 1000 kg is used in any period of 24 hours on the premises. Fumigations of soil under gas-proof sheeting in glasshouses where not more than 500 kg is used in any period of 24 hours on the premises. Fumigations of compost outdoors under gas-proof sheeting where not more than 10 kg of methyl bromide is used in any period of 24 hours on the premises. Fumigations under gas-proof sheeting inside structures other than glasshouses and

Column 1 <i>Fumigant</i>	Column 2 <i>Nature of fumigation</i>
Phosphine.	mushroom houses where not more than 5 kg of methyl bromide is used in each structure during any period of 24 hours. Fumigations of soil or compost in mushroom houses where not more than 5 kg of methyl bromide is used in any one fumigation in any period of 24 hours. Fumigations of containers where not more than 5 kg of methyl bromide is used in any one fumigation in a period of 24 hours. Fumigations carried out for research. Fumigations in fumigation chambers. Fumigations under gas-proof sheeting inside structures where not more than 1 kg of phosphine in each structure is used in any period of 24 hours. Fumigations in containers where not more than 0.5 kg of phosphine is used in any one fumigation in any period of 24 hours. Fumigations in individual impermeable packages. Fumigations in the open air to control or kill mammal pests.

SCHEDULE 9

Regulation 14(2)

NOTIFICATION OF CERTAIN FUMIGATIONS

PART I

PERSONS TO WHOM NOTIFICATIONS MUST BE MADE

1. In the case of a fumigation to be carried out within the area of a harbour authority, advance notification of fumigation shall, for the purposes of regulation 14(2)(a), be given to—

- (a) that authority;
- (b) an inspector appointed under section 19 of the 1974 Act, if that inspector so requires; and
- (c) where the fumigation—

Status: This is the original version (as it was originally made).

- (i) is to be carried out on a sea-going ship, the chief fire officer of the area in which the ship is situated and the officer in charge of the office of Her Majesty's Customs and Excise at the harbour, or
 - (ii) is the space fumigation of a building, the chief fire officer of the area in which the building is situated.
2. In the case of a fumigation, other than a fumigation to which paragraph (1) applies, advance notification of fumigation shall be given to—
- (a) the police officer for the time being in charge of the police station for the police district in which the fumigation is carried out;
 - (b) an inspector appointed under section 19 of the 1974 Act, if that inspector so requires; and
 - (c) where the fumigation is to be carried out on a sea-going ship or is the space fumigation of a building, the chief fire officer of the area in which the ship or building is situated.

PART II

INFORMATION TO BE GIVEN IN ADVANCE NOTICE OF FUMIGATIONS

3. The information to be given in a notification made for the purposes of regulation 14(2) shall include the following—
- (a) the name, address and place of business of the fumigator and his telephone number;
 - (b) the name of the person requiring the fumigation to be carried out;
 - (c) the address and description of the premises where the fumigation is to be carried out;
 - (d) the date on which the fumigation is to be carried out and the estimated time of commencement and completion;
 - (e) the name of the operator in charge of the fumigation; and
 - (f) the fumigant to be used.

EXPLANATORY NOTE

(This note is not part of the Regulations)

1. These Regulations re-enact, with modifications, the Control of Substances Hazardous to Health Regulations 1999 (S.I. 1999/437) (“the 1999 Regulations”). The 1999 Regulations imposed duties on employers to protect employees and other persons who may be exposed to substances hazardous to health and also imposed certain duties on employees concerning their own protection from such exposure, and prohibited the import into the United Kingdom of certain substances and articles from outside the European Economic Area.

2. The Regulations, with the exception of regulations 8, 9, 11(8), (10) and (11) and 14, implement as respects Great Britain—

- (a) Council Directive [78/610/EEC](#) (OJ No. L 197, 22.7.78, p.12) on the approximation of the laws, regulations and administrative provisions of the Member States on the protection of the health of workers exposed to vinyl chloride monomer,
 - (b) point 3 of Article 1 of Council Directive [89/677/EEC](#) (OJ No. L 398, 30.12.89, p.19) amending for the 8th time the Marketing and Use Directive insofar as that point relates to the importation, supply or use of benzene and substances containing benzene for such purposes,
 - (c) Council Directive [90/394/EEC](#) (OJ No. L 196, 26.7.90, p.1) on the protection of workers from risks related to exposure to carcinogens at work (sixth individual Directive within the meaning of Article 16(1) of Directive [89/391/EEC](#)) insofar as it relates to carcinogens other than asbestos,
 - (d) that part of Commission Directive [96/55/EC](#) (OJ No. L 231, 12.9.96, p.20) adapting to technical progress for the 2nd time Annex I to Council Directive [76/769/EEC](#) (“the Marketing and Use Directive”) (OJ No. L 262, 27.9.76, p.201) on the approximation of the laws, regulations and administrative provisions of the Member States relating to restrictions on the marketing and use of certain dangerous substances and preparations which relates to supply of specified substances for use at work,
 - (e) Council Directive [98/24/EC](#) (OJ No. L 131, 5.5.98, p.11) on the protection of the health and safety of workers from risks related to chemical agents at work (fourteenth individual Directive within the meaning of Article 16(1) of Directive [89/391/EEC](#)) insofar as it relates to risks to health from exposure to substances other than asbestos or lead, and
 - (f) Directive [2000/54/EC](#) (OJ No. L 262, 17.10.2000, p.21) of the European Parliament and of the Council on the protection of workers from risks related to exposure to biological agents at work (seventh individual Directive within the meaning of Article 16(1) of Directive [89/391/EEC](#)).
3. The Regulations are consistent with the provisions of Commission Directive [91/322/EEC](#) (OJ No. L 177, 5.7.91, p.22) on establishing indicative limit values by implementing Council Directive [80/1107/EEC](#) on the protection of workers from risks related to exposure to chemical, physical and biological agents at work.
4. In addition to minor and drafting amendments, the Regulations make the following changes of substance—
- (a) include certain further definitions (regulation 2);
 - (b) extend the matters to be considered when carrying out an assessment of the risk from exposure to substances hazardous to health (regulation 6);
 - (c) detail the measures which the employer must take to prevent or adequately control the exposure of his employees to substances hazardous to health (regulation 7);
 - (d) provide for further duties in respect of care and decontamination of personal protective equipment (regulation 9);
 - (e) provide for the keeping of an individual record of air monitoring where an employee is required to be under health surveillance (regulation 10);
 - (f) extend the duties on employers with respect to health surveillance where an employee is found to have an identifiable disease or adverse health effect caused by exposure to a substance hazardous to health (regulation 11);
 - (g) introduce a duty to ensure that the contents of containers and pipes for substances hazardous to health used at work are clearly identifiable (regulation 12(5));

Status: This is the original version (as it was originally made).

- (h) introduce a duty on the employer to prepare procedures, provide information and establish warning systems to deal with an emergency in the workplace related to the presence of a substance hazardous to health (regulation 13); and
 - (i) apply the extension to the meaning of “work” in Part I of the 1974 Act to all Group 2, 3, or 4 biological agents and transfer certain provisions relating to biological agents which had been in Schedule 3 of the 1999 Regulations to regulations 7 and 12.
5. Copies of the publications mentioned in the Regulations are obtainable as follows—
- (a) a list of the maximum exposure limits and occupational exposure standards which the Health and Safety Commission has approved is available in the publication “EH40, Occupational Exposure Limits” obtainable from HSE Books, PO Box 1999, Sudbury, Suffolk CO10 2WA; and
 - (b) British Standard BS EN 481 1993, referred to in regulation 2(1), relating to workplace atmospheres is obtainable from the British Standards Institution, BSI House, 389 Chiswick High Road, London W4 4AL.
6. A copy of the regulatory impact assessment prepared in respect of these Regulations can be obtained from the Health and Safety Executive, Economic Advisers Unit, Rose Court, 2 Southwark Bridge, London SE1 9HS. A copy of the transposition note in relation to implementation of the Directives set out in paragraph 2 can be obtained from the Health and Safety Executive, International Branch at the same address. Copies of both these documents have been placed in the Library of each House of Parliament.

NHS Greater Glasgow & Clyde

Clinical & Care Governance

Infection Prevention and Control Team 5 December 2017

Paper No: 17/24

Report on Concerns Raised re Queen Elizabeth University Hospital (QEUH) and Royal Hospital for Children (RHC)

Recommendation:- The committee are asked to note the concerns raised in relation to the QEUH and RHC and review the current status and actions being progressed.

Purpose of Paper:-

During September 2017 three consultant microbiologists in the South Sector raised a series of concerns about the facilities in QEUH and RHC and the structure of the Infection Prevention and Control (IPCT) Service within NHS Greater Glasgow and Clyde.

On the 4th of October 2017 Board and Acute Directors including the Board Director of Facilities, the Chief of Medicine for Diagnostics and members to the IPCT Senior Management team met with the consultants to discuss these concerns. The consultant microbiologists tabled a list of concerns and this paper identifies each with an action plan setting out the current situation and the steps taken or in progress to address the issues identified. The minutes of the October meeting are appended to this document with each specific issues raised identified and cross referenced to the action plan.

Key Issues to be considered:-

As above

Any Patient Safety /Patient Experience Issues:- yes

Any Financial Implications from this Paper:- no

Any Staffing Implications from this Paper:- no

Any Equality Implications from this Paper:- no

Any Health Inequalities Implications from this Paper:-no

Has a Risk Assessment been carried out for this issue? If yes, please detail the outcome:-

Highlight the Corporate Plan priorities to which your paper relates:- improving quality efficiency and effectiveness

Below is a list of the key themes raised by the Consultants.

Themes

- Positive Pressured Ventilated Lobbied (PPVL) Isolation Rooms.
- Royal Hospital for Children (RHC) – Protective Isolation – Haematology Oncology Unit.
- RHC – HEPA filters in Paediatric Intensive Care Unit (PICU).
- Queen Elizabeth University Hospital (QEUH) – Ward 4B – Upgrade to the Haematology Ward.
- Single Room Specification and Location of Areas that can be used for Protective Isolation.
- Cleaning of QEUH, RHC and Office Block
- Cleaning of Dishwashers in QEUH and RHC linked to a potential outbreak of exophiala
- Water Quality and Water Testing
- Plumbing in the Neurosurgical Block
- Decontamination of Respiratory Equipment
- Structure of the Infection Prevention and Control Team

Each specific item has been identified in the minute of the meeting and cross referenced in the associated action plan which is tabulated below.

Action Plan

Item	Issue	Current Position	Future Actions
1	PPVL rooms not compliant with SHTM standards	Facilities colleagues confirmed that there are 10 air changes per hour and a positive pressure of 10 pascals in the PPVL rooms which is consistent with SHBN 04-01.	Included in item 2
2	PPVL rooms do not provide appropriate protection for patients with infectious diseases of high consequence (IDHC) e.g. MERS, SARS This issue also exists in the Royal Hospital for Children	IDHC should be nursed in negative pressure rooms. These are not available in QEUH. In order to address this issue in the short term a patient pathway has been agreed by the Infectious Disease (ID) Clinicians whereby patients will be routed either to GRI or Lanarkshire ID unit. Chief Nurse (CN) for Paediatrics discussing with clinical teams a pathway for children.	Heath Protection Scotland (HPS) have been sent information on these rooms and we await their advice on whether they can be used for patients with IDHC or if not what actions could be taken to modify these rooms to provide negative pressure. This advice was sought in 2016 & 17.
3	Lack of isolation rooms in the emergency department.	ED was designed with input from clinical staff and observation of patients was a priority. There are single rooms in ED but not negatively pressured isolation rooms.	Property Procurement Facilities Management (PPFM) has commissioned a feasibility study to ascertain if negatively pressured rooms are technically feasible
4	Rooms not built to the standard expected as a tertiary referral centre.	The transfer of the Infectious Diseases Unit was a late addition to the project and was not fully commissioned as an ID unit at the outset.	Actions as described in item 2.
5	Microbiologists not aware of plans to upgrade areas.	Lead Infection Control Doctor (ICD) was aware of this proposal.	Work continues with input from the Coordinating ICD.
6	HEPA filters in PICU for the protection of patients in the Bone Marrow Transplant Unit (BMTU) that might need critical care during treatment. The BMTU is ward also referred to as ward 2A.	HEPA filters were installed within PICU/Ward 2a week commencing 6 November 2017, within room numbers 12 and 17 – previously installed within room 18. HEPA filter still to be fitted in room 5 (access to be agreed with clinical colleagues). HEPA filters were also fitted into RHC Ward 3c week commencing 13 November 2017 within rooms 9 & 10.	Work commenced mid November 2017, therefore ahead of May 2018, as noted above.

Item	Issue	Current Position	Future Actions
7	HEPA filters in prep room	HEPA filters have not been routinely fitted (as standard) within prep rooms, however HEPA filters are fitted within QEUH Ward 4b. Instruction required to determine whether HEPA filter should be fitted into RHC Ward 2a prep room.	A feasibility study will be undertaken to ascertain if HEPA filters can be installed in the prep room.
8	IVs prepared in treatment room.	IVs are prepared in the preparation room but not chemotherapy which is prepared in a specialist unit.	CN paediatrics confirmed that this was the standard practice.
9	Outbreak of Aspergillus associated with poor air quality	There were two cases of aspergillus associated with the ward in March 2017. This was fully investigated and was possibly associated with a leak into the ceiling space which was not immediately apparent. On review of cases in the new BMTU and the unit previously located in Yorkhill there is no significant increase in the number of cases of this infection. This was fully reported as per Chapter 3 of the National Infection Prevention and Control Manual to Health Protection Scotland.	HPS have been contacted for advice on what would be an appropriate regime for air monitoring in this area.
10	Concern that the statement issued advised that BMT services in RHC were unaffected by issues identified in the adult BMTU.	Clarification from the NHSGGC Comms Team “To the recollection of colleagues involved, the Communications team were not briefed at the time of the release about the adult BMT move of any testing underway at the Royal Hospital for Children. The final line of the press release of 8th July 2015 “Bone Marrow Transplant Service Temporary Relocation” was written to make clear to media that the move of the adult service did not include the paediatric service at the Royal Hospital for Children and that the latter was not moving. “	Clarification issued to the meeting attendees. No further action required. This perhaps appears to be misinterpretation of the media communication.
11	HEPA filters not in place in PICU	Action complete as previously agreed and noted within point 6.	

Item	Issue	Current Position	Future Actions
12	Increase in the number of line infections in Ward 2A	Two years' retrospective data were analysed in May 2017 and it was noted that there was an increase in line related infection. The initial baseline infection rate per 1000 total line days was 3.25 and this had risen to 6.33. A group led by CN Paediatrics first met in May 2017 to review this information and put actions in place to reduce this incidence. The last 4 months (July to October) have shown improvement in infection rates. CN Paediatrics presented a paper to the Board Infection Control Committee on the 27 November 2017 outlining several work streams and the most recent infection rates in this area.	There are currently four work streams in place to look at key initiatives to reduce line infections in BMTU, these include: • Line Insertion and access in theatre. • Access and Maintenance of lines • Staff Education • Patient and Parent engagement Next Steps From 1st December 2017 every CLABSI (line associated infections) will be subject to rigorous review utilising Event Cause Analysis methodology within 72 hours of a reported CLABSI
13	Increase in the number of line infections	IPCT participating in above work. Line related surveillance was subsequently picked up by the Directorate.	Ongoing assessment of surveillance activity and resource within the IPCT to enable IPCT to respond to local clinical needs.
14	Dr Redding concerned that the ongoing work would not accurately pick up any concerns.	• As above work streams in place re line infections. • IPCT audit process is in place and ongoing; this includes audit of the environment, audits of line and urinary catheter care. Audits of standard Infection Control Precautions (SIPS). • IPCT twice weekly visits. • GGC compliant with the National IPCT Manual – this lists all types of infections that should be reviewed and what should be reported if an outbreak or incident occurs. • Weekly report to Board and Acute Directors weekly on an IPC issues throughout GGC.	IPCT and CN Paediatrics will continue to have a clear focus on this area.
15	Microbiologists do not have the information to advise clinical staff on where to place immunocompromised patients.	Director of Regional Services stated that this had never been raised as an issue by clinicians within his service that care for patients who are immunocompromised. Most patients who are immunocompromised are cared for within this directorate. It was agreed by the group that placement of immunocompromised patients was a decision that should be taken by the clinical team looking after the individual patients.	Dr Peters agreed to circulate a document she had used in another board area. David Loudon (Director of PPFM) agreed to send the microbiologists a list of where the PPVL rooms were in the QEUH and RHC. It was agreed that this would be reviewed at the Regional Services Governance Forum

Item	Issue	Current Position	Future Actions
16	Infection rates are not being monitored.	• GGC compliant with the National IPCT Manual – this lists all types of infections that should be reviewed and what should be reported if an outbreak or incident occurs. • Every patient with a notifiable infection is reviewed and monitored. • NHSGGC is fully compliant with all elements of the national Mandatory Surveillance of Infection Programme (mainly specific surgical site and blood stream infections. • Weekly report on exceptions is sent to the Board Directors. • Monthly reports are sent to Senior Management teams. • All outbreak and incidents are reviewed by the Board, Partnership and Acute Infection Control Committees. • The most recent National Point Prevalence Survey in 2016 indicated that both the QEUH and RHC were under the national average in terms of the incidence of Hospital Acquired Infections.	ICM has invited HPS to review the NHSGGC systems for surveillance and reporting of infections – this assessment took place on the 29.11.17, the initial feedback was positive but we await the full report.
17	There are three air changes and chilled beam technology instead of the 6 air changes recommended.	There are three air changes in the single rooms within both QEUH and RHC.	Director of Facilities agreed to take this issue forward with NHS D&G to share learning with regards to this type of technology and draw to their attention concerns regarding cleaning of the beams. Action complete.
18	Use of cleaning agents.	NHSGGC has for several years changed the cleaning regimens each winter to include a chlorine based detergent as a strategy to reduce norovirus outbreaks. This switch commences on the 1st of November and continues until the 30 April each year or longer if the season is prolonged. This is not recommended in the National Infection Control Manual because of lack of scientific evidence but is put in place in GGC based on local site knowledge.	This policy and practice will continue unless new evidence emerges

Item	Issue	Current Position	Future Actions
19	Roles and responsibilities with regards to cleaning of the dishwashers in the ward pantries was not clear.	IPCT held an Incident Management team Meeting (IMT) on 22 nd of September. Dishwashers were removed from use until they could be serviced and re-sampled.	Catering staff agreed to assume the responsibility for cleaning of the dishwashers going forward.
20	Issue with dishwasher not picked up during routine monitoring.	GGC fully compliant with the National Monitoring of Domestic Services	Roles and responsibilities had been clarified and a process is now in place.
21	Cleaning of Temperature Control Values (TCVs)	TCVs are maintained in all high risk areas and plans are in place to carry this out in all areas despite this not being mandatory. Protocols are in place to manage this process.	Agreed works within QEUH-plant room 31, almost complete and being led by Site Maintenance Manager. Anticipated date of completion by end of January 2018.
22	Water testing is not as per national guidance	Board water safety is in place and water systems and processes are monitored as per national guidance.	None
23	Sewage leaks in institute not reported to microbiologists	Leaks in any clinical areas that required advice from an ICD are reported	Ensure reporting is ongoing.
24	Plumbing not replaced in Neuro Surgical Block	The Director of Regional Services advised that there is ongoing work in the neuro building that would because of its complexity, take several years to complete, in the meantime the new operating theatres were due to open in January 2018.	Works are ongoing as planned.
25	Perceived Increase in surgical site infections	Regional Services has funded 1.5 WTE surveillance nurses to carry out prospective surgical site surveillance in this area. For context, there are 3 surveillance nurses that provide this service for the rest of GGC therefore the investment in the INS to monitor SSI is significant. Although it is difficult to obtain benchmark rates for SSI in this area, continuous surveillance will pick out trends and therefore any increase. This is monitored via a group unique to Regional Services – the RS Surgical Site Infection Group. The group in turn reports into the Regional Service Clinical Governance Group	Continue to monitor trends in surgical site infection in this area.

Item	Issue	Current Position	Future Actions
26	Decontamination facilities	Most decontamination of equipment is conducted in the central Decontamination Unit or Endoscopy facilities. Respiratory equipment is easily damaged and advice from manufacturers is often difficult to implement. There should be dedicated facilities with established work flow patterns (dirty to clean). At this point in time the Decontamination group (which is a sub group of the Board Infection Control Committee) has give advice on many items of equipment and had obtained room designs which could be used if space was identified in QEUH and RHC. This has been submitted to management colleagues for consideration. In addition a list of specialist equipment that we require national advice on has been submitted to Health Protection Scotland.	Pursue HPS for advice regarding the list of equipment provided. Establish status of planning for new decontamination areas.
27	Roles of IPCT have changed	The current IPCT all have Job Descriptions which have been in place for several years. There is a clear documented governance structure that has been reviewed by Price Waterhouse Cooper and approved by the Infection prevention Committees within NHSGGC. There is a clear management structure which complies with the recommendations contained within the Vale of Leven Report and the Healthcare Environment Inspectorate Standards	A review of the roles and responsibilities of the Infection Control Doctors in South Glasgow will be undertaken by the Chief of Medicine for Diagnostics. The ICM has invited HPS to undertake a review of IPC surveillance and reporting systems in place.

Minutes of Meeting
Meeting Room L02-001, Teaching & Learning Centre
Queen Elizabeth University Hospital

Wednesday 4th October 2017 at 8:00am

PRESENT

Dr Jennifer Armstrong (Chair)	JA	Medical Director
David Loudon	DL	Director of Property, Procurement & FM
Morag Gardner	MG	Chief Nurse
Sandra McNamee	SMcN	Associate Nurse Director IPC
Ian Powrie	IP	Depute General Manager, Estates
Professor Brian Jones	BJ	Head of Service, Microbiology
Tom Walsh	TW	Infection Control Manager
Anne Harkness	AH	Director, South Sector
Jonathan Best	JB	Acting Chief Operating Officer
Gary Jenkins	GJ	Acting Director, North Sector
Dr Penelope Redding	PR	Consultant Microbiologist
Dr Christine Peters	CP	Consultant Microbiology
Dr Ash Deshpande	AD	Consultant Microbiologist/ICD
Dr Rachel Green	RG	Chief of Medicine, Diagnostics

In Attendance

Ann Lang (Minutes) PA, Infection Prevention and Control

Item	Action
1. Welcome & Introductions Dr Armstrong welcomed everyone to today's meeting to discuss Infection Control and estates issues at QEUH and RHC and round the table introductions were made. The group noted that colleagues from Women's and Children's Directorate were not in attendance but were aware of the issues raised and had helpfully submitted information via email which could inform the relevant areas of the discussion.	
2. Purpose, Format and Conduct of Meeting Dr Armstrong advised that a series of emails have been received from Dr Redding and Dr Peters regarding Infection Control and estates issues on the QEUH and RHC site. Dr Armstrong had requested a document setting out the issues of concern and thanked Drs Redding and Peters for providing the SBAR document which provided a helpful basis for the discussion. Dr Armstrong proposed that the meeting is focused on patient safety and a review and update on the current status of the issues identified. She asked that if there are any comments during the meeting if these could be addressed through the chair and to adhere to the GMC and Board guidance regarding respect, professionalism and working as part of a team. The group agreed the importance of issues raised being discussed in the context of the appropriate roles, responsibilities and governance structures.	

Item	Action
3. Review of SBAR / Concerns It was agreed to go through the items detailed in the SBAR from Dr Redding and Dr Peters, to look at the points raised and address any outstanding issues. Patient Placement Dr Redding outlined that there are challenges for the microbiologists regarding source isolation of infected patients. She said the current situation is that the positive pressure ventilated lobby rooms were not built to SHTM standard and she and others were concerned that they do not provide appropriate protection when managing a small number of patients with significant respiratory pathogens of high consequence such as MERS and MDRTB (Items 1&2). Dr Peters advised that Microbiologists and ICDs and ID colleagues feel there is a lack of provision for isolation rooms in A&E (Item 3). David Loudon replied that this specification was signed off by the board and clinical teams; he also confirmed that remedial work had been carried out due to issues raised at the snagging stage of the build. David also stated that although there were some modifications to the design the rooms did conform to SHTM 04-01 and that it was incorrect to state that this was not the case. Ian Powrie addressed specific points raised in respect of the ventilation specification and agreed to provide the detailed information to support this. Sandra McNamee commented that the inclusion of the Infectious Diseases service was a late amendment to the QEUH project and therefore not commissioned as an ID unit at the outset. The group noted that the Brownlee Clinical Team put a strong clinical case to the board to be co-located on QEUH site with the Intensive Care Unit and other critical clinical services. The issues identified were discussed with HPS at the time and they agreed to advise the Board on what standard these rooms would need to be to accommodate these patients. When this information has been received, estates colleagues will review the advice to determine if these modifications were feasible. Dr Redding stated she would like to see the evidence relating to this. Sandra advised that a follow up meeting took place with HPS on Monday 2nd October and that the relevant information was expected in the next few weeks, however in the meantime a patient pathway has been in place which routes these patients to appropriate isolation rooms in other hospitals. Dr Peters reported that these patients with significant airborne pathogens are being sent from A&E to the isolation rooms in ITU before being transferred to other hospitals as reported by ID colleagues. The group noted that this would be the case for other hospitals within NHS GGC and across NHS Scotland. Dr Peters however intimated that there is a risk of exposure to a large number of patients and staff and reiterated that, in her opinion, the ITU isolation rooms are not adequate for these types of patients. Furthermore other hospitals have not been recently built and are not a tertiary ID referral centre such as the QEUH (Item 4). Dr Redding also recognised that work may be ongoing but the microbiologists are not aware of this (Item 5). Anne Harkness advised that as these issues were raised she met with Directors and ID Physicians and they agreed a pathway for these patients to be transferred to other sites. She also commented that based on the external advice, unless the existing rooms can be modified in some way the only alternative was to build a new Infectious Disease Unit which would require a significant resource. David Loudon confirmed that changing the specification to negative pressure would be reviewed to assess technical feasibility.	

Item	Action
It was agreed to await the response from HPS and to deal with any further issues via the Acute and Board Infection Control Committees and the relevant Directorate Governance Committees. <u>Protective Isolation</u> Currently HEPA filters are not fitted in PICU isolation rooms (Item 6) and in the prep rooms in Ward 2A (Item 7). Dr Redding also commented that IVs are prepared in the treatment room (Item 8). She stated that there has been a perceived high rate of infections in immune compromised patients in Ward 2A and air quality has remained an issue in this ward since it opened. She also commented that there was an outbreak of Aspergillus (Item 9) in the unit and that there is still a risk to patients. Dr Peters said there was a public statement made by NHSGGC that BMT services at RHC are separate and unaffected and that both she and an ICD colleague had objected to the wording of the statement at the time and had asked to step down from ICD roles immediately after it was released. Dr Armstrong advised that she will check with the Comms team regarding the wording in the statement as this required some additional clarity around context (Item 10). With regards to the cases of Aspergillus, Sandra McNamee updated that there were two cases in March and April associated with a leak in the ceiling space. This was investigated and the tiles were removed and replaced with no further cases of Aspergillus. Ian Powrie advised that the HEPA filters were installed in two of the rooms in adult ITU but there has been no request to add these to isolation rooms throughout the adult or children's hospital. Work in RHC, Ward 2A is scheduled to start this month and with the scribe being signed off he can now contact the contractors to start the work. Sandra McNamee confirmed that this was raised at a meeting she attended yesterday and that she was aware that there is a plan to put HEPA filters in two of the rooms in PICU as contingency. (this action is complete) Ian Powrie said that the only reason this had not been done is that there was a requirement for the rooms to be unoccupied for 24 hours whilst this work was done and validation carried out and that up to this time it was not possible because the beds had been fully occupied and that there were ongoing discussions with the team in Ward 2A as to whether these patients could be accommodated in isolation rooms within other wards where HEPA Filters could be fitted to address the overspill contingency. Dr Peters commented that this was necessary in PICU, not just as an overspill for Ward 2A, but for these extremely vulnerable patients if they required intensive care treatment because of their illness (Item 11). Dr Redding advised that the clinical team in Ward 2A have reported that in their experience there seemed to be an increase in the number of line related infections and Sandra advised that this was investigated by Infection Prevention Control and the clinical team when first raised and work had been ongoing for several months (Item 12).	JA

Item	Action
She also reported that IPCT and the Clinical Team were working with Timothy Bradnock, Consultant Paediatric Surgeon to look at improvement work. Sandra noted that there was no effective benchmark available for this area. Dr Peters noted that rates of line infection were important to determine and that IPCT had stated there was no resource to do this (Item 13).	
Jen Rodgers, Chief Nurse has an improvement group looking at PVC and CVC bundles and Sandra said that this should have an impact on the number of infections. Dr Armstrong added that there has been a focused piece of work carried out in Ward 2A and they were on a weekly reporting process to ensure compliance with infection control standards had improved. Dr Redding was concerned that this may not accurately pick up any concerns (Item 14).	
In relation to the chemotherapy being prepared in the treatment rooms Gary Jenkins advised the group that chemo was prepared in a designated area and there was an audit process to confirm this. He also commented that this process had been reviewed recently and offered to provide Dr Redding the document that was produced. Dr Armstrong confirmed that chemo is not being made up in these rooms and is carried out in the Aseptic Dispensing unit. Dr Armstrong agreed to confirm this with Pharmacy.	JA
With regards to safe placement of immunocompromised patients, Dr Peters asked if there was a list of which rooms were of the standard that would be acceptable for this group of patients. She commented that when she worked in Crosshouse Hospital they had a list of where these particular patients could be placed. She said the microbiologists receive calls asking this question by clinical staff (Item 15).	
The group debated the definition and severity of immunocompromised patients and agreed, with input from Sandra McNamee and Prof Jones that this was a decision best considered by the clinical team looking after the individual patients. Dr Armstrong advised that this should be discussed at AICC and Gary Jenkins commented that this has not been raised as an issue via his Regional Clinical Governance Committee. Dr Armstrong recommended that this be addressed through the Regional Clinical Governance Committee. She also said it would be helpful to have a copy of the document that Dr Peters used in Crosshouse. Dr Redding reiterated that Microbiologists need to know which rooms are the most suitable for different categories of patients.	GJ CP
Dr Redding commented that she feels the infection rates are not being monitored (Item 16) and Dr Armstrong replied that the Board and Acute Directors receive a weekly report of all outbreaks and infection control incidents.	
Dr Armstrong agreed to ask the Women & Children directorate to take forward the points raised above.	JA
• <u>Single Side Room Accommodation</u> Dr Redding outlined that air changes per hour for all clinical accommodation in QEUH and RHC are 3 instead of 6 as per guidelines with the inclusion of chilled beam technology. The grills also collect dust as air is entrained over chilled beams which she suggested is not recommended in a healthcare setting (Item 17). Dr Peters advised this initially came to light when investigating issues regarding CF patients.	

Item	Action
David Loudon advised that Dumfries and Galloway have chilled beam technology and Dr Peters stated that Monklands Hospital is at the commissioning stage of a new build and suggested that we share our learning with them. It was agreed that it was important to share the GGC knowledge around chilled beam technology with colleagues in other Boards and David Loudon agreed to take this forward. Ian Powrie informed the group that all chilled beams on site are being cleaned and maintained and Dr Redding asked if the air changes can be changed from 3 to 6 in some rooms but not in all areas and David Loudon advised this was not realistically possible. Ian Powrie confirmed that cleaning and monitoring is being carried out to determine how quickly dust has built up and once this has been established a cleaning schedule will be organised and this can be shared with other hospitals. Dr Redding suggested involving Microbiologists regarding cleaning to look at the microbiological counts. Dr Jones suggested that rates of infection may also be a useful indicator. In this context Sandra McNamee reported that during the point prevalence survey QEUH was under the national average for infections and that all alert organism/conditions were monitored by the IPCT and that there were no indications that this site had a higher than average infection rates. It was noted that infections occurring post discharge would not be picked up by the point prevalence survey.	DL
<u>Cleaning</u> In relation to cleaning Dr Redding stated that cleaning agents were not being used on floors in clinical areas (Item 18). Dr Redding also outlined that dishwashers had not been cleaned, installed or operated according to manufacturing instructions (Item 19). This was brought to light with the investigation into CF patients with Exophiala. Sandra McNamee updated regarding the occurrence of Exophiala in CF patients and said this was referred to HPS as an amber HIIAT score but they downgraded this to a green HIIAT as this is considered to be a ubiquitous organism and the modes of spread, incubation period and occurrence in the population and environment was largely unknown. Dr Peters stated that she had already discussed the outbreak in her role as CF Microbiologist with mycology experts and given the striking epidemiology of increasing numbers, it is a reasonable hypothesis to assume a link to the dishwashers as a possible source. She had also discussed the HIIAT rating with HPS and agreed with green rating as the intervention with dishwasher was rapidly and appropriately dealt with. With reference to the cleaning agents Sandra McNamee responded that Actichlor cleans are used throughout the winter norovirus season which normally runs from November to April. She also stated that Actichlor was used in specific areas at the recommendation of IPCT, for example. Actichlor was used in GGH for a month in the summer due to an increase in CDI across the site. This has also been introduced for general cleaning into the wards with CF patients in QEUH and RHC, PICU, NICU and Ward 2A. At a recent meeting with HPS Sandra said HPS have found no evidence that using Actichlor is effective but further guidance was awaited. With regards to dishwashers in the ward area there had been some debate in the ward regarding whose responsibility it was to clean these but Sandra said this has been addressed. The manufacturer has come in to check the dishwashers and Catering Services have confirmed they will commence a cleaning programme for the dishwashers. It was also noted that Environmental Health Officers prefer dishwashers to be used over hand washing in sinks/basins.	

Item	Action
Dr Peters commented that the audit system did not pick up this problem (Item 20), and raised concerns about gaps in the environmental audit programmes and this was possibly the same with regards to ward refrigerators or other equipment. Sandra McNamee advised that nursing staff have a requirement to check the temperature in fridges and stated again that the catering department have agreed to take responsibility for the ward dishwashers. The group noted that dishwasher maintenance had been overlooked in the overall system but that this had now been rectified.	
• <u>Water Quality and Testing</u> In the SBAR it stated that all taps are fitted with TMVs and the cleaning and maintenance policy has not been reported and Dr Redding stated that we need to ensure this is up-to-date (Item 21) She also commented that the water in Ward 4B has not been tested to a high standard (Item 22).	
The group was assured that there was a Board Water Safety Policy in place that is approved by the appropriate governance committees.	
David Loudon reported that we have strict guidance on how to monitor water systems and processes are in place to comply with ECOPs. Ian Powrie also confirmed that water testing is carried out as per protocol and only exceptions are reported to the Infection Control Teams and this was previously agreed with Dr Inkster.	
He said testing is mainly carried out in high risk areas. David Loudon stated that we are not required to test all taps but a sample and that this was in accordance with guidance. He also confirmed that if requested by an ICD additional sampling was undertaken. Dr Deshpande said that Dr Inkster was managing the water testing and he perceived there was a problem with the environment. He said that he requested gram negative testing but did not receive the results from Estates. Ian Powrie replied that recent changes in staff in both estates and IPC could have been the reason why he did not receive the information. It was agreed that GGC are compliant with the water testing protocol. Dr Peters stated that the issue was not the overall testing protocols but the ICD role in requesting and receiving the results in a timely manner in exceptional circumstances where a water source of infection needed to be investigated.	
In relation to TMVs Ian Powrie advised that these are maintained in all high risk areas and they are working towards carrying this out in all areas. He said the end piece of the taps cannot be removed and an SBAR is in place for this. Estates are finalising the installation of a heat sanitation system and once complete this will be sent to the Board Water Safety Committee for approval.	
In terms of serratia Ian said they would test the water for this if requested by a clinician.	
• <u>Plumbing in Neuro Surgical Block</u> Dr Redding stated that there has been sewage leaking in the theatre suite since before 2015 and is still ongoing and not all incidents have been reported to ICDs (Item 23).	
Gary Jenkins advised that there is ongoing work in the neuro building that would, because of its complexity, take several years to complete. In the meantime the new operating theatres were due to open in January 2018.	

Item	Action
He stated that his directorate has a specific focus on IPC and that they had a dedicated group to look at surgical site infection. He said they funded 1.5 WTE surveillance nurses to carry out prospective surgical site surveillance in this area. Dr Armstrong updated that Dr Inkster carried out a detailed inspection of the area previously and she suggested that SSI surveillance was carried out here. Sandra McNamee advised for context that there are 3 surveillance nurses that cover all of GGC so the resource to actively do this in the INS was significant.	
She acknowledged that the ICDs were concerned about infections in EVD and stated that the clinical teams were currently developing an EVD bundle. Ian Powrie reported that remedial work was carried out in this building over the past year but that there had been an incident with sewage last week.	
There has been a delay in the opening of the ICE theatres as GGC were not satisfied with the standard but a programme of work has been agreed with the clinicians.	
Dr Peters said she requested to know the number of instances from when the theatres closed two years ago due to problems with the pipe work to date and she stated that she was told at the time of the initial problems that the plumbing was to be replaced (Item 24). Gary Jenkins responded that the pipes run through multiple floors and a process is in place with IPC and Capital Planning to take this forward in stages.	
Anne Harkness commented that increases in SSI should be discussed at the Regional Clinical IPC Group which Dr Deshpande is a representative of (Item 25). Ian Powrie advised that he has arranged to meet with Dr Deshpande and Dr Balfour to discuss the INS theatre issue.	
• <u>Decontamination Provision for Respiratory Clinics</u> The SBAR also stated that the decontamination facilities in both Paediatric and adult respiratory clinics have been identified as inadequate on a number of occasions (Item 26). Sandra McNamee informed that remedial actions have been put in place and a list of items has been sent to HPS for advice on how to decontaminate them.	
Dr Peters stated that QEUH ICD had not been informed of timeline for revision works to decontamination area to take place.	
• <u>Infection Control Structure</u> Dr Redding advised that the ICDs in the South Sector had stated that the roles within the Infection Control team are unclear and appear to have changed (Item 27). Dr Armstrong proposed that consideration is given to having a further separate meeting to discuss the issues referred to in this section. Jonathan Best offered to support this discussion.	

Item	Action
4. Agreement of Further Actions / Next Steps - Ian Powrie to provide documents supporting work on PPVL rooms - David Loudon to liaise with colleagues re GGC experience with chilled beams - In relation to safe patient placement and availability of isolation rooms, this is to be raised via the Regional Clinical Governance Committee. - Dr Peters to issue the group a copy of the document listing isolation rooms from Crosshouse Hospital. - Dr Armstrong to relay issues pertaining to Ward 2A to Women & Children directorate. - Dr Armstrong to confirm chemotherapy preparation in Aseptic Unit. - Consideration to be given to a further meeting with a smaller group to discuss the issues contained in the Infection Control Structure section of the SBAR. - Dr Armstrong to check with the Comms team regarding the wording in the public statement regarding BMT services	
5. A.O.C.B. Nil. Dr Armstrong thanked everyone for their attendance today.	

Page 666

	NHS GREATER GLASGOW & CLYDE CONTROL OF INFECTION COMMITTEE STANDARD OPERATING PROCEDURE (SOP)	Page	1 of 13
		Effective From	January 2024
	Patient Placement Guidance	Review Date	January 2026
		Version	Version 5
The most up-to-date version of this SOP can be viewed at the following website: www.nhsggc.org.uk/your-health/public-health/infection-prevention-and-control			

SOP Objective

To ensure that patients are cared for in the appropriate area in order to minimise the risk of cross-infection, and to protect immune compromised patients from environmental infection.

This SOP applies to all staff employed by NHS Greater Glasgow & Clyde and locum staff on fixed term contracts and volunteer staff.

KEY CHANGES FROM THE PREVIOUS VERSION OF THIS SOP

- Addition 2A RHC and 4B QEUH.

1. Responsibilities

Health Care Workers (HCW) must:

- Follow this SOP.
- Follow the advice of the Infection Prevention Control Team (IPCT)
- Escalate to line manager if they are unable to follow this SOP.

Managers must:

- Support HCWs in following this SOP.
- Cascade new policies/SOPs to clinical staff.

Infection Prevention and Control Teams must:

- Keep this SOP up-to-date.
- Provide education opportunities on this SOP.

Facilities / Estates Teams must:

- Carry out verifications on all rooms annually or following any works carried out on the room.
- Keep up-to-date verification records.

The most up-to-date version of this SOP can be viewed at the following website:

2. General Information on Specialist Ventilation

Across NHS Greater Glasgow and Clyde there are a number of specially ventilated rooms designed to protect patients within the healthcare environment from potentially harmful pathogens. The tables below provide a list of wards and rooms on each of the main hospital sites, indicating the type of ventilation and filtration available in each. This will direct staff to the correct placement of patients who are suspected or confirmed to have an airborne or high consequence infectious disease, as well as airborne protective isolation for immune compromised patients. Below is a description of what each type of ventilation means, while Table 1 should be used to guide staff to the type of patient that can be safely cared for in each.

What is a Positive Pressure Ventilated Lobby (PPVL) Room? (HEPA filtered air)

A PPVL room has a flow of air from the lobby which moves into the main room. The contaminated air is extracted via a vent in the en suite toilet when one is available. In all instances in QEUH and RHC there is an additional extract in variable locations in the ceiling of the patient room. The lobby itself is positively pressurised to both the patient's room and the outer corridor providing a barrier between the patient within the room and the surrounding ward. This movement of air effectively prevents infection spreading between the room and the surrounding ward. Some PPVL rooms have an air supply to the lobby via a filter (HEPA filter) providing some further protection for patients who are immunosuppressed within the room. It is important to keep the door to the main room and to the lobby closed when not in use to ensure that this flow of air is maintained. The pressure on the gauge from corridor to lobby should read +8 to +12 PA.

What is a Negatively Pressured Room?

A negative pressure room has a flow of air which moves from the corridor into the room preventing the escape of room air to the surrounding ward. The ventilation within the room is such that it dilutes any airborne pathogens which are circulating. The room provides a negative air flow / 'cascade' from ward corridor to lobby, and lobby to isolation room, whilst allowing control of room temperature. The room is validated for 10 air changes per hour within an isolation room and a pressure differential of -8Pa to -10Pa in relation to the corridor. It is important to keep the door to the main room and the lobby closed when not in use to ensure that this flow of air is maintained.

What is a Bone Marrow Transplant (BMT) Room?

BMT rooms are reserved for use by those patients who are highly susceptible to infection, for example, those undergoing bone marrow transplant. The air supply to the room is via a filter (HEPA filter) to further provide protection to the vulnerable patient within the room from external airborne pathogens such as fungi. These rooms are currently only located within Ward 2A Children Hospital and also Ward 4B in the QEUH, and are reserved for use by BMT patients.

3. Room Types

Type of Room	Patient allocation / suitability
PPVL with Lobby HEPA	Immunosuppressed patients, i.e. Haem-onc patients, should be prioritised for these rooms
	Immunosuppressed with chickenpox / measles
	Patients with Atypical Mycobacteria
	Patients with infections (non-airborne route)
Negative pressure	Chickenpox, Measles, Pathogens of High Consequence
	Tuberculosis (incl MDRTB and XDRTB) Prioritise airborne infection
BMT Rooms	Bone Marrow Transplant patients These are located in specialist units: QEUH 4B RHC 2A

4. Signage

Patient bedrooms with specialist ventilation will have a sign at the door indicating the specific ventilation afforded by that particular room. The signs will be one of the following (QEUH):

Negative Pressure Isolation Room

Pressure gauge should be between
-8Pa & -12Pa

If the positive side of the gauge is out of range please contact estates department
Help desk 5555

HEPA FILTERED PPVL Isolation Room

Pressure gauge should be between
+8Pa & +12Pa

If the positive side of the gauge is out of range please contact estates department
Help desk 5555

These templates only and should be modified for local use.

FACT-JACIE International Standards
for **HEMATOPOIETIC
CELLULAR THERAPY**
Product Collection, Processing, and Administration

SIXTH EDITION

INTERNATIONAL STANDARDS FOR HEMATOPOIETIC CELLULAR THERAPY PRODUCT COLLECTION, PROCESSING, AND ADMINISTRATION

Sixth Edition Version 6.1

NOTICE

These Standards are designed to provide minimum guidelines for programs, facilities, and individuals performing cellular therapy or providing support services for such procedures. These Standards are not intended to establish best practices or include all procedures and practices that a program, facility, or individual should implement if the standard of practice in the community or applicable governmental laws or regulations establish additional requirements. Each program, facility, and individual should analyze its practices and procedures to determine whether additional standards apply. Compliance with these Standards is not an exclusive means of complying with the standard of care in the industry or community or with local, national, or international laws or regulations.

The Foundation for the Accreditation of Cellular Therapy and the Joint Accreditation Committee – ISCT and EBMT expressly disclaim any responsibility for setting maximum standards and further expressly disclaim any responsibility, liability, or duty to member programs, directors, staff, or program donors or patients for any such liability arising out of injury or loss to any person by the failure of member programs, directors, or staff to adhere to the Standards or related guidance.

INTRODUCTION

The major objective of the *FACT-JACIE International Standards for Hematopoietic Cellular Therapy Product Collection, Processing, and Administration* (the Standards) is to promote quality medical and laboratory practice in hematopoietic progenitor cell transplantation and related therapies using hematopoietic-derived cellular products. These Standards apply to hematopoietic progenitor cells, defined as self-renewing and/or multi-potent stem cells capable of maturation into any of the hematopoietic lineages, lineage-restricted pluri-potent progenitor cells, and committed progenitor cells from hematopoietic sources (bone marrow, umbilical cord blood, peripheral blood, or other tissue source). These Standards also include nucleated cells, including mononuclear cells from any hematopoietic tissue source (marrow, peripheral blood, umbilical cord, and placental blood) collected for therapeutic use other than as hematopoietic progenitor cells. These Standards apply to all phases of collection, processing, storage, and administration of these cells, including donor selection and screening, in vitro manipulation such as removal or enrichment of specific cell populations, and cryopreservation. The FACT-JACIE Standards do not address the collection, processing, or administration of erythrocytes, platelets, mature granulocytes, plasma, or plasma-derived products intended for transfusion support.

For hematopoietic progenitor cells or mononuclear cells derived from umbilical cord and/or placental blood, these Standards apply only to the administration of the cellular therapy product, applying the clinical and processing standards for product preparation and transplantation as appropriate. Standards for cord blood collection and banking are available in a separate document, *NetCord-FACT International Standards for Cord Blood Collection, Banking, and Release for Administration*, available at www.factwebsite.org.

The FACT-JACIE Standards are published under the title *FACT-JACIE International Standards for Hematopoietic Cellular Therapy Product Collection, Processing, and Administration*, which accurately reflects the contributions of both organizations. The Foundation for the Accreditation of Cellular Therapy (FACT) was founded in 1996 by the American Society for Blood and Marrow Transplantation (ASBMT) and the International Society for Cellular Therapy (ISCT). The first edition of Standards was published that same year. The inspection and accreditation program based on these Standards was started in North America in 1997. The Joint Accreditation Committee of ISCT and EBMT (JACIE) was established in 1999. JACIE adopted the first edition of FACT Standards in its entirety. The second edition of FACT Standards (2002) was developed and published following joint review by FACT and JACIE. Subsequent editions of Standards have been jointly developed and approved by FACT and JACIE.

In addition, the use of *Hematopoietic* in the title is to define the scope of these standards due to an increasing number of accredited facilities that also support non-hematopoietic cellular therapies. Facilities pursuing accreditation for hematopoietic services in addition to other specialty services may consult these Standards as a single reference for all fundamental requirements.

Every effort has been made to incorporate into these Standards sound principles of quality medical and laboratory practice in cellular therapy. However, no standards can guarantee the successful outcome of such therapies. FACT-JACIE Standards are minimal guidelines that may be exceeded as deemed appropriate by the responsible personnel in individual facilities. Directors and Medical Directors of the Clinical Program, Marrow Collection Facility, Apheresis Collection Facility, and Processing Facility assume responsibility for adopting FACT-JACIE Standards as appropriate to the program or facility, and for setting more rigorous internal requirements where appropriate. Attempts have been made to conform these Standards to existing U.S. federal regulations and the requirements of the European Union Directives; however, compliance with these Standards does not guarantee compliance with all applicable regulations.

The Standards are structured to align similar standards among the three primary functions within a cellular therapy program: the Clinical Program, Collection Facility, and Processing Facility. Separate

sections exist for Marrow Collection Facilities and Apheresis Collection Facilities to recognize the inherent differences between these two facilities and the closer linkage between the Marrow Collection Facility and the Clinical Program.

Appendices are used to clarify requirements and simplify the Standards. In the sixth edition, standards requiring a minimum number of new patients were replaced by a standard requiring that the Clinical Program comply with a new appendix, the Minimum Number of New Patients for Accreditation. This change was made for clarity. No change was made to the minimum number of new patients required.

The Quality Management (QM) section for each area in the cellular therapy program was expanded in the third edition (2006) to incorporate US FDA regulatory requirements for donor screening, testing, and eligibility determination; labeling; and current Good Tissue Practices. In subsequent editions, the QM standards have been refined for clarity and realigned to reduce redundancy, but allow flexibility in the structure of quality management activities within a program. Under any structure, the Clinical Program must have assurances that QM activities are adequate in all areas that impact the patient or product. Because the clinical team usually plays a direct role in marrow collection, the Clinical Program QM requirements in Part B include marrow collection. A Marrow Collection Facility operating independently of a specific Clinical Program must comply with the QM section in Part B.

The Donor Selection, Evaluation, and Management sections in the Clinical Program and Collection Facility sections reflect the usual delineation of these responsibilities between clinical programs and collection facilities. The Collection Facility standards are focused on donor evaluation and management; the Clinical Standards have emphasis on donor selection. If a Collection Facility is primarily responsible for donor selection, that Collection Facility must comply with the applicable Clinical Program standards. The Donor Selection, Evaluation, and Management sections apply to both related and unrelated donors. Effort was made to clarify which standards apply to both allogeneic and autologous donors, and which standards apply only to allogeneic donors.

FACT-JACIE Standards require compliance with the most recent regulatory requirements and the most current resources from other initiatives in the field. This includes the Transplant Essential Data (TED) forms, the Minimum Essential Data – Form A (MED-A) forms, the Circular of Information (COI) donor testing and biohazard and warning label tables, and the ISBT 128 Standard Terminology. Links to these resources are available on the FACT website.

Both FACT and JACIE recognize the significant benefits of international standardization of coding and labeling in cellular therapy, and support the international efforts to implement ISBT 128. ISBT 128 is the global standard for terminology, identification, coding, and labeling of medical products of human origin, and has been designed to ensure accuracy and safety for the benefit of patients and donors world-wide. FACT-JACIE Standards require the use of this terminology for cellular therapy products as applicable, and require accredited programs to be actively implementing ISBT 128. Terminology current at the time of publication of these Standards is listed in A3 Definitions. Terminology is frequently updated by ICCBBA, the organization responsible for the international maintenance of the ISBT 128 standard. Accredited programs must be registered with ICCBBA, receive notification of these changes, and make appropriate revisions if needed.

Implementation of ISBT 128 will include the use of scanned information at the time of product release from collection, receipt into the laboratory, and at distribution from the processing facility. It is understood that full implementation of ISBT 128 requires a transition period, and that organizations inspected soon after publication of this edition of Standards may not have completed this process. At a minimum, “actively implementing” includes completion of most of the following:

- 1) Registration with ICCBBA;
- 2) Evidence of a written implementation plan that includes a timeline;
- 3) Implementation of the current terminology;

- 4) Identification of information technology needs and solutions;
- 5) Identification or creation of appropriate product codes;
- 6) Label designs according to the requirements of ICCBBA for Cellular Therapy Products;
- 7) Label validation;
- 8) Use of scanned information at the time of product release from collection, receipt into the laboratory, and at distribution from the processing facility.

This sixth edition of Standards includes additional significant changes. A detailed summary is available on the FACT website. Most important to note are:

- 1) Increased emphasis on outcome analysis and improvement.
 - a) Clinical Programs are required to assess at least 30 day, 100 day, and one year survival, and to compare one year survival to national or international outcome data. For US programs, at a minimum, the one year survival should be within the expected range as defined for that program by the CIBMTR Transplant Center-Specific Outcome Data. Corrective action plans will be expected if these outcomes are not achieved.
 - b) Clinical Programs must regularly assess allogeneic transplant recipients for evidence of acute and chronic graft versus host disease according to an established grading scale, and actively evaluate patients for post-transplant late effects.
 - c) Clinical Programs must also regularly assess central venous catheter infections.
- 2) Reporting of autologous transplant results is now recommended.
- 3) New requirements were added for pharmacists and physicians-in-training who are involved in the care of hematopoietic cell therapy patients.
- 4) Continuing education minimum requirements have been specifically defined as ten hours per year in topics related to hematopoietic cell therapies.
- 5) Requirements specific to immune effector cells used to modulate an immune response were added as interim standards.

These Standards (Version 6.0) are effective June 1, 2015. All accredited programs and facilities are expected to be in compliance with these Standards by that date.

ACCREDITATION

The basis for FACT or JACIE accreditation is documented compliance with the current edition of Standards through submitted documents and an on-site inspection. Although there are joint FACT-JACIE Standards, FACT and JACIE maintain separate and parallel accreditation processes. All inspections are conducted by persons qualified by training and experience in the area of cellular therapy they inspect, and who are affiliated with an accredited facility, have completed inspector training, and have a working knowledge of FACT-JACIE Standards and of their application to various aspects of the cellular therapy program.

- 1) A clinical hematopoietic progenitor cell/therapeutic cell transplantation program may apply for accreditation alone or in conjunction with the collection facility and/or the processing facility with which it is associated. All facilities applying together should submit pre-inspection data together. A clinical program must use a collection facility and a processing facility that meet FACT-JACIE Standards and have a clearly defined contractual or reporting relationship.
 - a) Clinical Program accreditation may be for allogeneic transplantation, autologous transplantation, or both.
 - b) Clinical Program accreditation may be for transplantation of adult patients, pediatric patients, or both. As detailed in the Standards, consultants and support services appropriate to the patient population are required.

- 2) A cell collection facility or service (peripheral blood or bone marrow) may apply for accreditation as an integral part of a clinical transplant program, as an independent collection service providing cell collection services for one or more clinical transplant programs, or in conjunction with a cell processing facility if the services of collection and processing/storage are functionally linked. An accredited cell collection facility may provide services for clinical transplant programs that are or are not FACT or JACIE accredited, but shall use a processing facility that meets FACT-JACIE Standards and have a clearly defined contractual or reporting relationship.
- 3) A cell processing facility may apply for accreditation as an integral part of a clinical transplant program, as part of a collection service or facility, or as an independent cell processing facility that processes and stores products for clinical programs or collection facilities. An accredited processing facility may provide services for clinical transplant programs and/or collection services that are or are not FACT or JACIE accredited.
- 4) A clinical program that provides cellular therapy services other than hematopoietic progenitor cell transplantation in addition to hematopoietic cell transplantation requires only a single accreditation according to these Standards.
- 5) A clinical program that provides cellular therapy services other than hematopoietic progenitor cell transplantation may apply for FACT accreditation with a hematopoietic progenitor cell transplantation program provided that the definition of and requirements for a single clinical program are met. A program that utilizes the same group of physicians and serves the same patient population, with common directorship, protocols, and staffing, would meet this requirement.
- 6) A cell collection or processing facility that collects or processes hematopoietic progenitor cell therapy products in addition to other investigational products may apply for FACT accreditation for all activities and document compliance with the FACT-JACIE Standards.
- 7) If a facility does not collect or process hematopoietic cell therapy products but wishes to apply for FACT accreditation, the facility personnel should consult the current edition of the *FACT Common Standards for Cellular Therapies*.

An accreditation cycle is three years for FACT, and is four years for JACIE. Accredited facilities must complete an interim report(s) during the accreditation cycle as directed by FACT or JACIE. Accredited facilities are reinspected routinely every three years (FACT) or four years (JACIE), and may also be reinspected in response to complaints or information that a facility may be non-compliant with FACT-JACIE Standards, in response to significant changes in the program and/or facility, or as determined by FACT or JACIE. Accreditation may be suspended or terminated if a facility fails to comply with the Standards.

TERMINOLOGY, TENETS, ABBREVIATIONS, AND DEFINITIONS

PART A

- A1 Terminology
- A2 Tenets
- A3 Abbreviations
- A4 Definitions

PART A: TERMINOLOGY, TENETS, ABBREVIATIONS, AND DEFINITIONS**A1 TERMINOLOGY**

For purposes of these Standards, the term *shall* means that the standard is to be complied with at all times. The term *should* indicates an activity that is recommended or advised, but for which there may be effective alternatives. The term *may* is permissive and is used primarily for clarity.

A2 TENETS

Basic tenets for compliance with these Standards include, but are not limited to:

- A2.1 Where applicable laws and regulations include more stringent requirements than these Standards, those laws and regulations supersede the Standards. Conversely, when these Standards are more stringent than applicable laws and regulations, the Standards must be followed.
- A2.2 Applicant organizations are responsible for providing verifiable documentation of evidence of compliance with these Standards.
- A2.3 Standards related to services not provided by the applicant do not apply to the applicant organization. The burden to demonstrate that a requirement is not applicable rests with the applicant organization.

A3 ABBREVIATIONS

The following abbreviations cover terms used in these Standards:

ABO	Major human blood group including erythrocyte antigens, A, B, O
AC	Accompany
AF	Affixed
Anti-	Antibody to the antigen designated
APP	Advanced Practice Provider/Professional
ASBMT	American Society for Blood and Marrow Transplantation
ASFA	American Society for Apheresis
ASHI	American Society for Histocompatibility and Immunogenetics
AT	Attached
ATMP	Advanced Therapy Medicinal Product
CAR	Chimeric antigen receptor
CE	(formerly EC) European Conforming
CFR	Code of Federal Regulations
CIBMTR	Center for International Blood and Marrow Transplant Research
CLIA	Clinical Laboratory Improvement Amendments
CME	Continuing Medical Education
CMS	Centers for Medicare & Medicaid Services
CMV	Cytomegalovirus
CNS	Central nervous system
COA	Certificate of Analysis
CRS	Cytokine release syndrome
CTP	Cellular therapy product
DLI	Donor lymphocyte infusion

<i>DNA</i>	Deoxyribonucleic acid
<i>EBMT</i>	European Society for Blood and Marrow Transplantation
<i>ECP</i>	Extracorporeal photopheresis
<i>EFI</i>	European Federation for Immunogenetics
<i>EU</i>	European Union
<i>FACT</i>	Foundation for the Accreditation of Cellular Therapy
<i>FDA</i>	U. S. Food and Drug Administration
<i>GMP</i>	Good Manufacturing Practices
<i>GTP</i>	Good Tissue Practices
<i>GVHD</i>	Graft versus Host Disease
<i>HCT/Ps</i>	Human cells, tissues, or cellular or tissue-based products
<i>HLA</i>	Human leukocyte antigen
<i>HPC</i>	Hematopoietic progenitor cell
<i>IDE</i>	Investigational Device Exemption
<i>IND</i>	Investigational New Drug
<i>ISCT</i>	International Society for Cellular Therapy
<i>JACIE</i>	Joint Accreditation Committee – ISCT and EBMT
<i>MNC</i>	Mononuclear cell
<i>MSC</i>	Mesenchymal stromal cell or mesenchymal stem cell
<i>NC</i>	Nucleated cell
<i>NMDP</i>	National Marrow Donor Program
<i>OSHA</i>	Occupational Safety and Health Administration
<i>QM</i>	Quality management
<i>RBC</i>	Red blood cell
<i>Rh</i>	Rhesus system of human red cell antigens; used in this document to refer to the Rh(D) antigen only, unless otherwise specified
<i>SCTOD</i>	Stem Cell Therapeutics Outcomes Database
<i>SOP</i>	Standard operating procedure
<i>US</i>	United States
<i>USDA</i>	United States Department of Agriculture
<i>WMDA</i>	World Marrow Donor Association

A4 DEFINITIONS

Accompany: To go, be together with, or be available to the appropriate individual(s) electronically, but not affixed or attached. Written or printed information that must accompany a cellular therapy product must be in a sealed package with, or alternatively, be attached or affixed to, the cellular therapy product container.

Accreditation cycle: The period of time from the awarding of accreditation until its expiration as set, and subject to change, by FACT or JACIE. At publication of these Standards, this period is three (3) years for FACT-accredited programs and four (4) years for JACIE-accredited programs.

Advanced practice provider/professional: Physician Assistant, Nurse Practitioner, or other licensed Advanced Practitioner authorized by the applicable legal authority to provide primary patient care with physician oversight. Physician Assistants are formally trained and licensed or certified by the applicable authority to provide diagnostic, therapeutic, and preventive health care services with physician supervision. Advanced Nurse Practitioner includes certified nurse anesthetists, nurse practitioners, certified nurse midwives, and clinical nurse specialists.

Adverse event: Any unintended or unfavorable sign, symptom, abnormality, or condition temporally associated with an intervention that may or may not have a causal relationship with the intervention, medical treatment, or procedure. Adverse reaction is a type of adverse event.

Adverse reaction: A noxious and unintended response suspected or demonstrated to be caused by the collection or infusion of a cellular therapy product or by the product itself.

Affix: To adhere in physical contact with the cellular therapy product container.

Allogeneic: The biologic relationship between genetically distinct individuals of the same species.

Ambulatory setting: An environment of patient care outside of an inpatient hospital.

Apheresis: A medical technology in which the blood of a donor is separated into its component parts, the desired component is removed, and the remaining components are returned to the donor.

Aseptic technique: Practices designed to reduce the risk of microbial contamination of cellular therapy products, reagents, specimens, recipients, and/or donors.

Attach: To fasten securely to the cellular therapy product container by means of a tie tag or comparable alternative. Any information required to be attached to a cellular therapy product container may alternatively be affixed.

Attending physician: The physician who is responsible for the delivery and oversight of care provided to cellular therapy recipients and who meets all qualifications defined in these Standards.

Audit: Documented, systematic evaluation to determine whether approved policies or procedures have been properly implemented and are being followed.

Autologous: Derived from and intended for the same individual.

Available for distribution: The time at which the cellular therapy product may leave the control of the facility.

Biological product deviation: Any event associated with the manufacturing of a cellular therapy product, including testing, processing, packing, labeling, or storage, or with the holding or distribution of a licensed biological product, if that event meets the following criteria:

Either:

- Represents a deviation from current good manufacturing practice (or current good tissue practices), applicable regulations, applicable standards, or established specifications that may affect the safety, purity, or potency of that product; or
- Represents an unexpected or unforeseeable event that may affect the safety, purity, or potency of that product; and
 - Occurs in your facility or another facility under contract with you; and
 - Involves a distributed biological product.

Calibrate: To set measurement equipment against a known standard.

CD34: The 115 kD glycoprotein antigen, expressed by 1-2% of normal bone marrow mononuclear cells, that is defined by a specific monoclonal antibody (anti-CD34) using the standardized cluster of differentiation (CD) terminology.

Cellular therapy: The administration of products with the intent of providing effector cells in the treatment of disease or support of other therapy.

Cellular therapy product: Somatic cell-based product (e.g., mobilized HPC, mononuclear cells, cord blood cells, mesenchymal stromal cells, T cells, natural killer cells) that is procured from a donor and intended for processing and administration.

Chimeric antigen receptor: Artificial receptor that combines an antigen specificity domain coupled with an intracellular signaling domain typically expressed by an immune effector cell (e.g., T cell or natural killer cell).

Chimerism testing: A diagnostic test (e.g., molecular, cytogenetic, or FISH) conducted after allogeneic stem cell or bone marrow transplantation to detect the relative ratio of donor and recipient cell populations in the peripheral blood and/or bone marrow.

Circular of Information: An extension of container labels that includes the use of the cellular therapy product, indications, contraindications, side effects and hazards, dosage, and administration recommendations.

Clinical Program: An integrated medical team housed in a defined location that includes a Clinical Program Director and demonstrates common staff training, protocols, procedures, quality management systems, clinical outcome analysis, and regular interaction among clinical sites.

Collection: Any procedure for procuring and labeling a cellular therapy product regardless of technique or source.

Collection Facility: An entity providing the service of cellular therapy product collection.

Competency: Ability to adequately perform a specific procedure or task according to direction.

Complaint: Any written, oral, or electronic communication about a problem associated with a cellular therapy product or with a service related to the collection, processing, storage, distribution, or administration of a cellular therapy product.

Cord blood: The whole blood, including HPC, collected from placental and umbilical cord blood vessels after the umbilical cord has been clamped.

Corrective action: Action taken to eliminate the root causes of an existing discrepancy or other undesirable situation to prevent recurrence.

Courier: An individual trained and competent in transport or shipping of cellular therapy products.

Critical: The quality of any element employed in cellular therapy product manufacturing to potentially change the identity, purity, potency, or safety of the cellular therapy product if altered or omitted. "Element" includes, but is not limited to, materials, equipment, personnel, documents, or facilities. For example, DMSO is a critical reagent because omitting it from the freezing medium will cause loss of cells during freezing and thawing.

Current Good Tissue Practice: The methods used in, and the facilities and controls used for, the manufacture of cellular therapy products to prevent the introduction or transmission of communicable diseases, including all steps in collection, donor screening and testing, processing, storage, labeling, packaging, and distribution.

Current Good Manufacturing Practice: The set of current practices followed by entities producing drug and biologic products, including cellular therapy products, to ensure that the products

produced meet specific requirements for identity, strength, quality, and purity. In the US, cGMPs are enforced under Section 501(B) of the Federal Food, Drug, and Cosmetic Act (21USC351). Cellular therapy products that are extensively manipulated or that are used for non-homologous purposes are examples of products controlled under cGMP regulations. Similar requirements are delineated by the European Union as EU-GMP, and other countries such as United Kingdom, Australia, Canada, and Singapore have equally well-developed systems of regulations.

Cytokine release syndrome: A non-antigen-specific toxicity that occurs as a result of high-level immune activation. For example, a reaction from the release of cytokines from cells targeted by an antibody or immune effector cells.

Designee: An individual with appropriate education, experience, or expertise who is given the authority to assume a specific responsibility. The person appointing the designee retains ultimate responsibility.

Distribution: Any transportation or shipment of a cellular therapy product that has been determined to meet release criteria or urgent medical need requirements.

Donor: A person who is the source of cells or tissue for a cellular therapy product.

Donor advocate: An individual distinct from the cellular therapy recipient's primary treating physician whose main obligation is to protect the interests, well-being, and safety of the donor. The donor advocate may help the donor understand the process, the procedures, and the potential risks and benefits of donation.

Donor lymphocyte infusion (DLI): A type of therapy given to a patient who has already received an allogeneic hematopoietic progenitor cell transplant from the same donor. The donor lymphocytes may kill remaining cancer cells, facilitate full donor chimerism, or provide a source of antigen specific immunity. The DLI cell source may be whole blood, bone marrow, mononuclear cells collected by apheresis with or without mobilization, cord blood, or cellular subsets purified from these source products. The active cell type may include T lymphocytes, NK cells, or B lymphocytes. May also be referred to as donor leukocyte infusion.

Electronic record: A record or document consisting of any combination of text, graphics, or other data that is created, stored, modified, or transmitted in digital form by a computer.

Critical electronic record: Electronic record system under facility control that is used as a substitute for paper, to make decisions, to perform calculations, or to create or store information used in critical procedures.

Eligible: An allogeneic cellular therapy product donor for whom all the donor screening and testing have been completed in accordance with applicable laws and regulations and who has been determined to be free of risk factor(s) for relevant communicable diseases.

Engraftment: The reconstitution of recipient hematopoiesis with blood cells and platelets from a donor.

Errors and Accidents: Any unforeseen or unexpected deviations from applicable regulations, standards, or established specifications that may affect the safety, purity, or potency of a cellular therapy product.

Establish and maintain: A process to define, document in writing (including electronically), implement, follow, review, and, as needed, revise on an ongoing basis.

Exceptional release: Removal of a product that fails to meet specified criteria from quarantine or in-process status for distribution through a defined approval process.

Expansion: Growth of one or more cell populations in an *in vitro* culture system.

Extracorporeal photopheresis: An apheresis technique in which the patient's blood is collected into a specialized instrument, centrifuged, and separated into a leukocyte-depleted fraction (which is returned to the patient unmanipulated) and mononuclear "buffy coat" enriched plasma. The mononuclear cell-enriched fraction is incubated with 8-methoxypsoralen in the presence of ultraviolet A (UVA) radiation, and, upon completion of the procedure, reinfused into the patient.

Facility: A location where activities covered by these Standards are performed, including but not limited to determination of donor eligibility or suitability, product collection, processing, storage, distribution, issue, or administration.

Fellow: A physician who is in a training program in a medical specialty after completing residency, usually in a hospital or academic setting.

Fresh: A cellular therapy product that has never been cryopreserved.

Hematopoietic progenitor cells (HPC): A cellular therapy product that contains self-renewing and/or multi-potent stem cells capable of maturation into any of the hematopoietic lineages, lineage-restricted pluri-potent progenitor cells, and committed progenitor cells, regardless of tissue source (bone marrow, umbilical cord blood, peripheral blood, or other tissue source).

Hematopoietic progenitor cellular therapy: The administration of HPC product with the intent of providing effector functions in the treatment of disease or in support of other therapy.

Human cells, tissues, or cellular or tissue-based products (HCT/Ps): Articles containing or consisting of human cells or tissues that are intended for implantation, transplantation, infusion, or transfer into a human recipient.

Immune effector cell: A cell that has differentiated into a form capable of modulating or effecting a specific immune response.

Ineligible: An allogeneic cellular therapy product donor for whom all the donor screening and testing has been completed in accordance with the applicable laws and regulations and who has identified risk factor(s) for relevant communicable diseases.

Institutional Review Board or Ethics Committee: A Board or Committee established by an institution in accordance with the regulations of the relevant governmental agency to review biomedical and behavioral research that involves human subjects and is conducted at or supported by that institution.

ISBT 128: A global standard for the identification, labeling, and information transfer of human blood, cell, tissue, and organ products.

Key position: A job category with responsibilities that significantly affect the provision of service or product safety and quality.

Label: Written, printed, or graphic material affixed to, attached to, or accompanying a cellular therapy product container or package. Labels must contain the information as defined by applicable standards, laws, and regulations.

Labeling: The process of creating and applying the cellular therapy product label, including confirmation of the presence and accuracy of the required information as defined in these Standards.

**Late Effect:* A health problem that occurs months or years after a disease is diagnosed or after treatment has been administered. Late effects may be caused by the primary disease or its treatment, and may include physical, mental, or social problems and/or secondary cancers.

Licensed health care professional: An individual who has completed a prescribed program of health-care related study and has been certified, registered, or licensed by the applicable authority in the jurisdiction in which he or she is performing services to perform duties within the scope of practice of that certificate, registration, or license.

Manipulation: An ex vivo procedure(s) that selectively removes, enriches, expands, or functionally alters the cellular therapy product.

Minimally Manipulated: Processing that does not alter the relevant biological characteristics of cells or tissues. For structural tissue, processing that does not alter the original relevant characteristics of the tissue relating to the tissue's utility for reconstruction, repair, or replacement.

More than minimally manipulated: Processing that does alter the relevant biological characteristics of cells or tissues. For structural tissue, processing that does alter the original relevant characteristics of the tissue relating to the tissue's utility for reconstruction, repair, or replacement. Products that are more than minimally manipulated are referred to as Advanced Therapy Medicinal Products in the European Union.

Unmanipulated: A cellular therapy product as obtained at collection and not subjected to any form of processing.

Manufacturing: Activity that includes, but is not limited to, any or all steps in the recovery, processing, packaging, labeling, storage, or distribution of any human cellular or tissue-based product, and/or the screening and testing of a cell or tissue donor.

Marrow collection: Harvest of bone marrow for transplantation to achieve hematopoietic reconstitution in the recipient or for further cellular therapy product manufacture. This does not include marrow aspirations intended for diagnostic purposes.

Materials management: An integrated process for planning and controlling all steps in the acquisition and use of goods or supply items (materials) used for the collection or processing of cellular therapy products to determine whether these materials are of adequate quality and quantity and available when needed. The materials management system combines and integrates the material selection, vendor evaluation, purchasing, expediting, storage, distribution, and disposition of materials.

Microbial: Related to infectious agents including bacterial and fungal organisms.

Negative selection: The manipulation of a cellular therapy product such that a specific cell population(s) is reduced.

New patient: An individual undergoing the specified type of transplantation (allogeneic, autologous, or syngeneic) for the first time in the Clinical Program, whether or not that patient was previously treated by that Clinical Program.

Orientation: An introduction to guide one in adjusting to new surroundings, employment, or activity.

Outcome analysis: The process by which the results of a therapeutic procedure are formally assessed.

Partial label: The minimum essential elements that must be affixed to all cellular therapy product containers at all times.

Physician-in-training: A physician in one of the postgraduate years of clinical training. Can be referred to as resident, fellow, registrar, or other designation, depending on the setting. The length of training varies according to the specialty.

Policy: A document that defines the scope of an organization, explains how the goals of the organization will be achieved, and/or serves as a means by which authority can be delegated.

Positive selection: The manipulation of a cellular therapy product such that a specific cell population(s) is enriched.

Potency: The therapeutic activity of a product as indicated by appropriate laboratory tests or adequately developed and controlled clinical data.

Preparative (conditioning) regimen: The treatment(s) used to prepare a patient for stem cell transplantation (e.g., chemotherapy, monoclonal antibody therapy, radiation therapy).

Preventive action: Action taken to eliminate the root cause and prevent occurrence of a potential discrepancy or other undesirable situation.

Procedure: A document that describes in detail the process or chronological steps taken to accomplish a specific task; work instructions; a procedure is more specific than a policy.

Process: A goal-directed, interrelated series of actions, events, or steps.

Process control: The standardization of processes in order to produce predictable output.

Process development: The series of procedures performed in order to develop a final process that achieves the required results.

Processing: All aspects of manipulation, cryopreservation, packaging, and labeling of cellular therapy products regardless of source, including microbial testing, preparation for administration or storage, and removal from storage. Processing does not include collection, donor screening, donor testing, storage, or distribution.

Processing Facility: A location where cellular therapy product processing activities are performed in support of the Clinical Program. A Processing Facility may be part of the same institution as the Clinical Program or may be part of another institution and perform these functions through contractual agreement.

Product identity: Unique title that identifies the cellular composition of the product in a way that can be directly tied back to a manufacturing entity or process (e.g., a protocol number, a commercial product title, or a site-defined unique identifier).

Product sample: A representative quantity of product removed from the cellular therapy product; an aliquot.

***Products:* The ISBT 128 Cellular Therapy Class product database name and definition (format: type of cells, comma, source of cells) for products collected from marrow, peripheral blood, and cord blood are as follows:

Subcategory 1: At collection the product code will describe the composition of the cell therapy products. It can be HPC, NC, or MNC. These products can be collected for direct infusion without further manipulation. HPCs may be further manipulated, but would retain the class name HPC if they are used as a source of hematopoietic progenitor cells. If these products undergo modification such as cryopreservation and thawing, the class will not change but the modification is added into the product description as an attribute.

CONCURRENT PLASMA, APHERESIS: Plasma collected from the donor as part of an apheresis cell collection procedure.

HPC, APHERESIS: A cell product containing hematopoietic progenitor cells obtained by apheresis.

HPC, CORD BLOOD: A cell product containing hematopoietic progenitor cells obtained from cord blood.

HPC, MARROW: A cell product containing hematopoietic progenitor cells obtained from bone marrow.

HPC, WHOLE BLOOD: A cell product containing hematopoietic progenitor cells obtained from whole blood.

MNC, APHERESIS: A cell product containing mononuclear cells obtained by apheresis.

MNC, UMBILICAL CORD TISSUE: A cell product containing mononuclear cells derived from umbilical cord tissue.

NC, CORD BLOOD: A cell product containing nucleated cells obtained from cord blood.

NC, MARROW: A cell product containing nucleated cells obtained from bone marrow.

NC, WHOLE BLOOD: A cell product containing nucleated cells obtained from whole blood.

Subcategory 2: After enumeration or manufacture/processing of the collected products, the product may be identified by the target cell population. These class names are based on desired cell population thought to be present in the product.

DC, APHERESIS: A cell product containing dendritic cells obtained by apheresis.

DC, CORD BLOOD: A cell product containing dendritic cells obtained from cord blood.

DC, MARROW: A cell product containing dendritic cells obtained from bone marrow.

DC, WHOLE BLOOD: A cell product containing dendritic cells obtained from whole blood.

INVESTIGATIONAL PRODUCT: A product for an investigational study that is accompanied by appropriate identifying study information. This class may be used for a specific product that may be part of a blinded comparison study. Products labeled as Investigational Product may include different doses or may include an active product or a placebo.

MALIGNANT CELLS, APHERESIS: A cell product containing malignant cells obtained by apheresis.

MALIGNANT CELLS, MARROW: A cell product containing malignant cells obtained from marrow.

MALIGNANT CELLS, WHOLE BLOOD: A cell product containing malignant cells obtained from whole blood.

MSC, CORD BLOOD: A cell product containing mesenchymal stromal cells derived from cord blood.

MSC, MARROW: A cell product containing mesenchymal stromal cells derived from bone marrow.

MSC, WHARTON'S JELLY: A cell product containing mesenchymal stromal cells derived from Wharton's jelly.

NK CELLS, APHERESIS: A cell product containing natural killer cells obtained by apheresis.

NK CELLS, CORD BLOOD: A cell product containing natural killer cells obtained from cord blood.

NK CELLS, MARROW: A cell product containing natural killer cells obtained from bone marrow.

NK CELLS, WHOLE BLOOD: A cell product containing natural killer cells obtained from whole blood.

T CELLS, APHERESIS: A cell product containing T cells obtained by apheresis.

T CELLS, CORD BLOOD: A cell product containing T cells obtained from cord blood.

T CELLS, MARROW: A cell product containing T cells obtained from bone marrow.

T CELLS, WHOLE BLOOD: A cell product containing T cells obtained from whole blood.

Proficiency test: A test to evaluate the adequacy of testing methods and equipment and the competency of personnel performing testing.

Protocol: A written document describing steps of a treatment or procedure in sufficient detail such that the treatment or procedure can be reproduced repeatedly without variation.

Purity: Relative freedom from extraneous matter in the finished product, whether or not harmful to the recipient or deleterious to the product.

Qualification: The establishment of confidence that equipment, supplies, and reagents function consistently within established limits.

Qualified person: A person who has received training, is experienced, and has documented competence in the task assigned.

Quality: Conformance of a product or process with pre-established specifications or standards.

Quality assurance: The actions, planned and performed, to provide confidence that all systems and elements that influence the quality of the product or service are working as expected or exceed expectations individually and collectively.

Quality assessment: The actions, planned and performed, to evaluate all systems and elements that influence the quality of the product or service.

Quality audit: A documented, independent inspection and review of a facility's quality management activities to verify, by examination and evaluation of objective evidence, the degree of compliance with those aspects of the quality program under review.

Quality control: A component of a quality management program that includes the activities and controls used to determine the accuracy and reliability of the establishment's personnel, equipment, reagents, and operations in the manufacturing of cellular therapy products, including testing and product release.

Quality improvement: The actions, planned and performed, to implement changes designed to improve the quality of a product or process.

Quality management: The integration of quality assessment, assurance, control, and improvement in cellular therapy activities.

Quality management plan: A written document that describes the systems in place to implement the quality management program.

Quality management program: An organization's comprehensive system of quality assessment, assurance, control, and improvement. A quality management program is designed to prevent, detect, and correct deficiencies that may adversely affect the quality of the cellular therapy product or increase the risk of communicable disease introduction or transmission. May also be referred to by other terms.

Quality Unit: The personnel responsible for Quality Management. Under good manufacturing practices, the quality unit must be independent from manufacturing, facility, and medical oversight and have final authority and oversight for the release of cellular therapy products.

Quarantine: The identification or storage of a cellular therapy product in a physically separate area clearly identified for such use, or through use of other procedures such as automated designation to prevent improper release of that product. Also refers to segregated storage of products known to contain infectious disease agents to reduce the likelihood of cross-contamination.

Record: Documented evidence that activities have been performed or results have been achieved. A record does not exist until the activity has been performed.

Release: Removal of a product from quarantine or in-process status when it meets specified criteria.

Release criteria: The requirements that must have been met before a cellular therapy product may leave the control of the Collection or Processing Facility.

Safety: Relative freedom from harmful effects to persons or products.

Shipping: The physical act of transferring a cellular therapy product within or between facilities. During shipping the product leaves the control of trained personnel at the distributing or receiving facility.

Standard Operating Procedures (SOP) Manual: A compilation of policies and procedures with written detailed instructions required to perform procedures. The SOP Manual may be in electronic or paper format.

Standards: The current edition of the *FACT-JACIE International Standards for Hematopoietic Cellular Therapy Product Collection, Processing, and Administration*, which may be referred to herein as "Standards" or "FACT-JACIE Standards."

Storage: Holding a cellular therapy product for future processing, distribution, or administration.

Suitable: Donor or recipient suitability refers to issues that relate to the general health or medical fitness of the donor or recipient to undergo the collection procedure or therapy.

Syngeneic: The biologic relationship between identical twins.

Target cell population: A cell population that is expected to be affected by an action or that is believed to be mainly responsible for a given activity.

Time of collection: The time of day at the end of the cellular therapy product collection procedure.

Trace: To follow the history of a process, product, or service by review of documents.

Track: To follow a process or product from beginning to end.

Transplantation: The infusion of allogeneic, autologous, or syngeneic HPC with the intent of providing transient or permanent engraftment in support of therapy of disease.

Transport: The physical act of transferring a cellular therapy product within or between facilities. During transportation the product does not leave the control of trained personnel at the transporting or receiving facility.

Unique: Being the only one of its kind or having only one use or purpose.

Unique identifier: A numeric or alphanumeric sequence used to designate a given cellular therapy product with reasonable confidence that it will not be used for another purpose.

Unplanned deviation: The action of departing from an established course or accepted standard without intent.

Urgent medical need: A situation in which no comparable cellular therapy product is available and the recipient is likely to suffer death or serious morbidity without the cellular therapy product.

Validation: Confirmation by examination and provision of objective evidence that particular requirements can consistently be fulfilled. A process is validated by establishing, by objective evidence, that the process consistently produces a cellular therapy product meeting its predetermined specifications.

Variance: A planned deviation from recommended practice or standard operating procedure approved as the best course of action when adherence to the established course or accepted standard was not feasible or possible .

Verification: The confirmation of the accuracy of something or that specified requirements have been fulfilled.

Verification typing: HLA typing performed on an independently collected sample with the purpose of verifying concordance of that typing assignment with the initial HLA typing assignment. Concordance does not require identical levels of resolution for the two sets of typing but requires the two assignments be consistent with one another.

Viability: Living cells as defined by dye exclusion, flow cytometry, or progenitor cell culture.

Written: Documentation in human readable form.

**A portion of the definition that can be located in the National Cancer Institute at the National Institutes of Health's NCI Dictionary of Cancer Terms: <http://www.cancer.gov/dictionary?Cdrid=390292>.*

CLINICAL PROGRAM STANDARDS**PART B**

- B1 General
- B2 Clinical Unit
- B3 Personnel
- B4 Quality Management
- B5 Policies and Procedures
- B6 Allogeneic and Autologous Donor Selection,
Evaluation, and Management
- B7 Recipient Care
- B8 Clinical Research
- B9 Data Management
- B10 Records

PART B: CLINICAL PROGRAM STANDARDS**B1: GENERAL**

-
- B1.1 The Clinical Program shall consist of an integrated medical team that includes a Clinical Program Director(s) housed in a defined location(s).
- B1.1.1 The Clinical Program shall demonstrate common staff training, protocols, procedures, quality management systems, clinical outcome analysis, and regular interaction among all clinical sites.
-
- B1.2 The Clinical Program shall use cell collection and processing facilities that meet FACT-JACIE Standards with respect to their interactions with the Clinical Program.
- B1.2.1 If cellular therapy products are received directly by the Clinical Program from a third-party provider, the following responsibilities at a minimum shall be defined in a written agreement:
- B1.2.1.1 Traceability and chain of custody of cellular therapy products.
- B1.2.1.2 Cellular therapy product storage and distribution.
- B1.2.1.3 Verification of cellular therapy product identity.
-
- B1.3 The Clinical Program shall abide by all applicable laws and regulations.
- B1.3.1 The Clinical Program shall be licensed, registered, or accredited as required by the appropriate governmental authorities for the activities performed.
-
- B1.4 The Clinical Program shall have a designated transplant team that includes a Clinical Program Director, a Quality Manager, and a minimum of one (1) additional attending transplant physician. The designated transplant team shall have been in place for at least twelve (12) months preceding initial accreditation.
-
- B1.5 The Clinical Program shall comply with the Minimum Number of New Patients for Accreditation table in Appendix I.
-

B2: CLINICAL UNIT

-
- B2.1 There shall be a designated inpatient unit of appropriate location and adequate space and design that minimizes airborne microbial contamination.
-
- B2.2 There shall be a designated outpatient care area that protects the patient from transmission of infectious agents and allows, as necessary, for appropriate patient isolation; confidential examination and evaluation; and administration of intravenous fluids, medications, or blood products.
-
- B2.3 When the preparative regimen, cellular therapy product administration, or initial post-transplant care is provided in an ambulatory setting, there shall be a designated area with appropriate location and adequate space and design to minimize the risk of airborne microbial contamination.
-
- B2.4 Facilities used by the Clinical Program shall be maintained in a clean, sanitary, and orderly manner.
-
- B2.5 There shall be provisions for prompt evaluation and treatment by a transplant attending physician available on a 24-hour basis.
-
- B2.6 There shall be written guidelines for communication, patient monitoring, and prompt transfer of patients to an intensive care unit, emergency department, or equivalent when appropriate.
-
- B2.7 There shall be attending physician oversight if general medical physicians, physicians in training, or APPs provide care to transplant patients. The scope of responsibility of general medical physicians or APPs shall be defined.
-
- B2.8 There shall be a pharmacy providing 24-hour availability of medications needed for the care of transplant patients.
- B2.8.1 Pharmacies shall have access to medications adequate to treat expected complications of immune effector cell administration, including cytokine release syndrome.
-

- B2.9 There shall be access to renal support under the direction of nephrologists and trained personnel.
-
- B2.10 There shall be 24-hour availability of CMV-appropriate and irradiated blood products needed for the care of transplant recipients.
-
- B2.11 Clinical Programs performing allogeneic transplantation shall use HLA testing laboratories that are capable of carrying out DNA-based intermediate and high resolution HLA-typing and are appropriately accredited by the American Society for Histocompatibility and Immunogenetics (ASHI), European Federation for Immunogenetics (EFI), or other accrediting organizations providing histocompatibility services appropriate for hematopoietic cellular therapy transplant patients.
-
- B2.12 Chimerism testing shall be performed in laboratories accredited for the techniques used.
-
- B2.13 There shall be an intensive care unit or equivalent coverage available.
-
- B2.14 The Clinical Program shall be operated in a manner designed to minimize risks to the health and safety of employees, patients, donors, visitors, and volunteers.
-
- B2.15 The Clinical Program shall have a written safety manual that includes instructions for action in case of exposure, as applicable, to liquid nitrogen; communicable disease; and to chemical, biological, or radiological hazards.
-

B3: PERSONNEL

B3.1 CLINICAL PROGRAM DIRECTOR

- B3.1.1 The Clinical Program Director shall be a physician appropriately licensed or certified to practice medicine in the jurisdiction in which the Clinical Program is located and shall have achieved specialist certification in one or more of the following specialties: Hematology, Medical Oncology, Pediatric Immunology, or Pediatric Hematology/Oncology. A physician trained prior to requirements for specialty training may serve as the Clinical Program Director if he/she has documented experience in the field of HPC transplantation extending over ten (10) years.

- B3.1.2 The Clinical Program Director shall have two (2) years of experience as an attending physician responsible for the direct clinical management of HPC transplant patients in the inpatient and outpatient settings.
- B3.1.3 The Clinical Program Director shall be responsible for administrative and clinical operations, including compliance with these Standards and applicable laws and regulations.
- B3.1.4 The Clinical Program Director shall be responsible for all elements of the design of the Clinical Program including quality management, the selection and care of patients and donors, and cell collection and processing, whether internal or contracted services.
- B3.1.5 The Clinical Program Director shall have oversight of the medical care provided by all members of the Clinical Program.
 - B3.1.5.1 The Clinical Program Director or designee shall be responsible for verifying the knowledge and skills of members of the Clinical Program once per accreditation cycle, at minimum.
- B3.1.6 The Clinical Program Director shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
 - B3.1.6.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation.

B3.2 ATTENDING PHYSICIANS

- B3.2.1 Attending physicians shall be appropriately licensed to practice medicine in the jurisdiction of the Clinical Program and should be specialist certified or trained in one of the following specialties: Hematology, Medical Oncology, Immunology, or Pediatric Hematology/Oncology.
 - B3.2.1.1 Clinical Programs performing adult transplantation shall have at least one attending physician who has achieved specialist certification in Hematology, Medical Oncology, or Immunology.
 - B3.2.1.2 Clinical Programs performing pediatric transplantation shall have at least one attending physician who has achieved specialist certification in Pediatric Hematology/Oncology or Pediatric Immunology.
- B3.2.2 Attending physicians shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
 - B3.2.2.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation.

B3.3 TRAINING FOR CLINICAL PROGRAM DIRECTORS AND ATTENDING PHYSICIANS

- B3.3.1 Attending physicians shall each have had a minimum total of one year of supervised training in the management of transplant patients in both inpatient and outpatient settings.
- B3.3.2 Clinical training and competency shall include the management of autologous and/or allogeneic transplant recipients, as applicable.
- B3.3.3 Clinical Program Directors and attending physicians shall have received specific training and maintain competency in each of the following areas as applicable to the Clinical Program's services:
 - B3.3.3.1 Indications for HPC transplantation.
 - B3.3.3.2 Selection of suitable recipients and appropriate preparative regimens.
 - B3.3.3.3 Allogeneic and autologous donor selection, evaluation, and management.
 - B3.3.3.4 Donor and recipient informed consent.
 - B3.3.3.5 Administration of ABO incompatible cellular therapy products.
 - B3.3.3.6 Administration of preparative regimens.
 - B3.3.3.7 Administration of growth factors for HPC mobilization and for post-transplant hematopoietic cell reconstitution.
 - B3.3.3.8 HPC product infusion and patient management.
 - B3.3.3.9 Management of neutropenic fever.
 - B3.3.3.10 Diagnosis and management of infectious and non-infectious pulmonary complications of transplantation.
 - B3.3.3.11 Diagnosis and management of fungal disease.
 - B3.3.3.12 Diagnosis and management of veno-occlusive disease of the liver and other causes of hepatic dysfunction.
 - B3.3.3.13 Management of thrombocytopenia and bleeding, including recognition of disseminated intravascular coagulation.
 - B3.3.3.14 Management of hemorrhagic cystitis.
 - B3.3.3.15 Management of mucositis, nausea, and vomiting.
 - B3.3.3.16 Monitoring and management of pain.
 - B3.3.3.17 Graft versus host disease.
 - B3.3.3.18 Cytokine release syndrome.

- B3.3.3.19 Tumor lysis syndrome.
- B3.3.3.20 Macrophage activation syndrome.
- B3.3.3.21 Cardiac dysfunction.
- B3.3.3.22 Renal dysfunction.
- B3.3.3.23 Respiratory distress.
- B3.3.3.24 Neurologic toxicity.
- B3.3.3.25 Anaphylaxis.
- B3.3.3.26 Infectious and noninfectious processes.
- B3.3.3.27 Diagnosis and management of HPC graft failure.
- B3.3.3.28 Evaluation of post-transplant cellular therapy outcomes.
- B3.3.3.29 Evaluation of late effects of allogeneic and autologous transplants, including cellular, pharmacologic, and radiation therapy.
- B3.3.3.30 Documentation and reporting for patients on investigational protocols.
- B3.3.3.31 Applicable regulations and reporting responsibilities for adverse events.
- B3.3.3.32 Palliative and end of life care.
- B3.3.4 Additional specific clinical training and competency required for physicians in Clinical Programs requesting accreditation for allogeneic HPC transplantation shall include:
 - B3.3.4.1 Identification, evaluation, and selection of HPC source, including use of donor registries.
 - B3.3.4.2 Donor eligibility determination.
 - B3.3.4.3 Methodology and implications of human leukocyte antigen (HLA) typing.
 - B3.3.4.4 Management of patients receiving ABO incompatible HPC products.
 - B3.3.4.5 Diagnosis and management of immunodeficiencies and opportunistic infections.
 - B3.3.4.6 Diagnosis and management of acute graft versus host disease.
 - B3.3.4.7 Diagnosis and management of chronic graft versus host disease.
- B3.3.5 The attending physicians shall be knowledgeable in the following procedures:
 - B3.3.5.1 HPC processing.

- B3.3.5.2 HPC cryopreservation.
- B3.3.5.3 Bone marrow harvest procedures.
- B3.3.5.4 Apheresis collection procedures.
- B3.3.5.5 Extracorporeal photopheresis for GVHD.
- B3.3.5.6 Washing and diluting of cellular therapy products.
- B3.3.5.7 Cellular therapy product administration.

B3.4 PHYSICIANS-IN-TRAINING

- B3.4.1 Physicians-in-training shall be licensed to practice in the jurisdiction of the Clinical Program and shall be limited to a scope of practice within the parameters of their training and licensure and shall be appropriately supervised.
- B3.4.2 Physicians-in-training shall receive specific training and develop competency in transplant-related skills, including but not limited to those listed in B3.3.3 and B3.3.4.

B3.5 ADVANCED PRACTICE PROVIDERS/PROFESSIONALS

- B3.5.1 APPs shall be licensed to practice in the jurisdiction of the Clinical Program and shall be limited to a scope of practice within the parameters of their training and licenses.
- B3.5.2 APPs shall have received specific training and maintain competency in the transplant-related skills that they routinely practice including but not limited to those listed in B3.3.3 and B3.3.4.
- B3.5.3 APPs shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
 - B3.5.3.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation.

B3.6 CLINICAL TRANSPLANT TEAM

- B3.6.1 Clinical Programs performing pediatric transplantation shall have a transplant team trained in the management of pediatric patients.
- B3.6.2 The Clinical Program shall have access to licensed physicians who are trained and competent in marrow collection and utilize a marrow collection facility that meets these Standards.

- B3.6.3 The Clinical Program shall have access to personnel who are trained and competent in cellular therapy product collection by apheresis and utilize an apheresis collection facility that meets these Standards.

B3.7 NURSES

- B3.7.1 The Clinical Program shall have nurses formally trained and experienced in the management of patients receiving cellular therapy.
- B3.7.2 Clinical Programs treating pediatric patients shall have nurses formally trained and experienced in the management of pediatric patients receiving cellular therapy.
- B3.7.3 Training and competency shall include:
- B3.7.3.1 Hematology/oncology patient care, including an overview of the cellular therapy process.
 - B3.7.3.2 Administration of preparative regimens.
 - B3.7.3.3 Administration of blood products, growth factors, cellular therapy products, and other supportive therapies.
 - B3.7.3.4 Care interventions to manage cellular therapy complications, including, but not limited to, cytokine release syndrome, tumor lysis syndrome, cardiac dysfunction, respiratory distress, neurologic toxicity, renal and hepatic failure, disseminated intravascular coagulation, anaphylaxis, neutropenic fever, infectious and noninfectious processes, mucositis, nausea and vomiting, and pain management.
 - B3.7.3.5 Recognition of cellular therapy complications and emergencies requiring rapid notification of the transplant team.
 - B3.7.3.6 Palliative and end of life care.
- B3.7.4 There shall be written policies for all relevant nursing procedures, including, but not limited to:
- B3.7.4.1 Care of immunocompromised patients.
 - B3.7.4.2 Administration of preparative regimens.
 - B3.7.4.3 Administration of cellular therapy products.
 - B3.7.4.4 Central venous access device care.
 - B3.7.4.5 Administration of blood products.
 - B3.7.4.6 Detection and management of immune effector cellular therapy complications including, but not limited to, those listed in B3.7.3.4.

- B3.7.5 There shall be an adequate number of nurses experienced in the care of transplant patients.
- B3.7.6 There shall be a nurse/patient ratio satisfactory to manage the severity of the patients' clinical status.

B3.8 PHARMACISTS

- B3.8.1 Pharmacists shall be licensed to practice in the jurisdiction of the Clinical Program and shall be limited to a scope of practice within the parameters of their training and licensure.
- B3.8.2 Training shall include:
 - B3.8.2.1 An overview of hematology/oncology patient care, including the cellular therapy process, cytokine release syndrome, and neurological toxicities.
 - B3.8.2.2 Therapeutic drug monitoring, including, but not limited to, anti-infective agents, immunosuppressive therapy, anti-seizure medications, and anticoagulation.
 - B3.8.2.3 Monitoring for and recognition of drug/drug and drug/food interactions and necessary dose modifications.
 - B3.8.2.4 Recognition of medications that require adjustment for organ dysfunction.
- B3.8.3 Pharmacists shall be involved in the development and implementation of guidelines or SOPs related to the pharmaceutical management of cellular therapy recipients.
- B3.8.4 Designated transplant pharmacists shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
 - B3.8.4.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation and cytokine release syndrome and neurological toxicities resulting from cellular therapies.

B3.9 CONSULTING SPECIALISTS

- B3.9.1 The Clinical Program shall have access to certified or trained consulting specialists and/or specialist groups from key disciplines who are capable of assisting in the management of patients requiring medical care, including, but not limited to:
 - B3.9.1.1 Surgery.
 - B3.9.1.2 Pulmonary medicine.
 - B3.9.1.3 Intensive care.

- B3.9.1.4 Gastroenterology.
- B3.9.1.5 Nephrology.
- B3.9.1.6 Infectious disease.
- B3.9.1.7 Cardiology.
- B3.9.1.8 Pathology.
- B3.9.1.9 Psychiatry.
- B3.9.1.10 Radiology.
- B3.9.1.11 Radiation oncology with experience in large-field (e.g., total body or total lymphoid) irradiation treatment protocols, if radiation therapy is administered.
- B3.9.1.12 Transfusion medicine.
- B3.9.1.13 Neurology.
- B3.9.1.14 Ophthalmology.
- B3.9.1.15 Obstetrics/Gynecology.
- B3.9.1.16 Dermatology.
- B3.9.1.17 Palliative and end of life care.

B3.9.2 A Clinical Program treating pediatric patients shall have consultants, as defined in B3.9.1, qualified to manage pediatric patients.

B3.10 QUALITY MANAGER

- B3.10.1 There shall be a Clinical Program Quality Manager to establish and maintain systems to review, modify, and approve all policies and procedures intended to monitor compliance with these Standards and/or the performance of the Clinical Program.
- B3.10.2 The Clinical Program Quality Manager should have a reporting structure independent of cellular therapy product manufacturing.
- B3.10.3 The Clinical Program Quality Manager shall participate in ten (10) hours of educational activities related to cellular therapy and/or quality management annually at a minimum.
 - B3.10.3.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation.

B3.11 SUPPORT SERVICES STAFF

B3.11.1 The Clinical Program shall have one or more designated staff with appropriate training and education to assist in the provision of pre-transplant patient evaluation, treatment, and post-transplant follow-up and care. Designated staff shall include:

B3.11.1.1 Dietary staff capable of providing dietary consultation regarding the nutritional needs of the recipient, including enteral and parenteral support, and appropriate dietary advice to avoid food-borne illness.

B3.11.1.2 Social Services staff.

B3.11.1.3 Psychology Services staff.

B3.11.1.4 Physical Therapy staff.

B3.11.1.5 Data Management staff sufficient to comply with B9.

B4: QUALITY MANAGEMENT

B4.1 There shall be an overall Quality Management Program that incorporates key performance data from clinical, collection, and processing facility quality management.

B4.1.1 The Clinical Program Director or designee shall have authority over and responsibility for ensuring that the Quality Management Program is effectively established and maintained.

B4.1.2 The Clinical Program Director shall annually review the effectiveness of the Quality Management Program.

B4.2 The Clinical Program shall establish and maintain a written Quality Management Plan.

B4.2.1 The Clinical Program Director or designee shall be responsible for the Quality Management Plan.

B4.2.2 The Clinical Program Director or designee shall review and report to staff quality management activities, at a minimum, quarterly.

B4.2.3 The Clinical Program Director or designee shall not have oversight of his/her own work if this person also performs other tasks in the Clinical Program.

B4.3 The Quality Management Plan shall include, or summarize and reference, an organizational chart of key positions and functions within the cellular therapy program, including clinical, collection, and processing.

B4.3.1 The Quality Management Plan shall include a description of how these key positions interact to implement the quality management activities.

B4.4 The Quality Management Plan shall include, or summarize and reference, policies and Standard Operating Procedures addressing personnel requirements for each key position in the Clinical Program. Personnel requirements shall include at a minimum:

B4.4.1 A current job description for all staff.

B4.4.2 A system to document the following for all staff:

B4.4.2.1 Initial qualifications.

B4.4.2.2 New employee orientation.

B4.4.2.3 Initial training and retraining when appropriate for all procedures performed.

B4.4.2.4 Competency for each critical function performed.

B4.4.2.5 Continued competency at least annually.

B4.4.2.6 Continuing education.

B4.5 The Quality Management Plan shall include, or summarize and reference, a comprehensive system for document control and management.

B4.5.1 There shall be policies and procedures for development, approval, implementation, review, revision, and archival of all critical documents.

B4.5.2 There shall be a current listing of all active critical documents that shall comply with the document control system requirements. Controlled documents shall include at a minimum:

B4.5.2.1 Policies, protocols, and Standard Operating Procedures.

B4.5.2.2 Worksheets.

B4.5.2.3 Forms.

B4.5.2.4 Labels.

B4.5.3 The document control policy shall include:

B4.5.3.1 A standardized format for policies, procedures, worksheets, and forms.

- B4.5.3.2 Assignment of numeric or alphanumeric identifier and title to each document and document version regulated within the system.
 - B4.5.3.3 A procedure for document approval, including the approval date, signature of approving individual(s), and the effective date.
 - B4.5.3.4 A system to protect controlled documents from accidental or unauthorized modification.
 - B4.5.3.5 A system for document change control that includes a description of the change, the signature of approving individual(s), approval date(s), effective date, and archival date.
 - B4.5.3.6 Archived policies and procedures, the inclusive dates of use, and their historical sequence shall be maintained for a minimum of ten (10) years from archival or according to governmental or institutional policy, whichever is longer.
 - B4.5.3.7 A system for the retraction of obsolete documents to prevent unintended use.
 - B4.5.3.8 A system for record creation, assembly, review, storage, archival, and retrieval.
 - B4.5.4 There shall be a process for the regular review and assessment of records to identify recurring problems, potential points of failure, or need for process improvement.
-
- B4.6 The Quality Management Plan shall include, or summarize and reference, policies and procedures for establishment and maintenance of written agreements with third parties whose services impact the clinical care of the recipient and/or donor.
 - B4.6.1 Agreements shall include the responsibility of the third-party facility performing any step in collection, processing, or testing to comply with applicable laws and regulations and these Standards.
 - B4.6.2 Agreements shall be dated and reviewed on a regular basis.
-
- B4.7 The Quality Management Plan shall include, or summarize and reference, policies and procedures for documentation and review of outcome analysis and cellular therapy product efficacy to verify that the procedures in use consistently provide a safe and effective product.
 - B4.7.1 Criteria for cellular therapy product safety, product efficacy, and/or the clinical outcome shall be determined and shall be reviewed at regular time intervals.
 - B4.7.2 Both individual cellular therapy product data and aggregate data for each type of cellular therapy product and/or recipient type shall be evaluated.

- B4.7.3 Review of outcome analysis and/or product efficacy shall include at a minimum:
- B4.7.3.1 For HPC products intended for hematopoietic reconstitution, time to engraftment following product administration.
 - B4.7.3.2 For immune effector cells, an endpoint of clinical function as approved by the Clinical Program Director.
 - B4.7.3.3 Overall and treatment-related morbidity and mortality at thirty (30) days, one hundred (100) days, and one (1) year after cellular therapy product administration.
 - B4.7.3.4 Acute GVHD grade within one hundred (100) days after allogeneic transplantation.
 - B4.7.3.5 Chronic GVHD grade within one (1) year after allogeneic transplantation.
 - B4.7.3.6 Central venous catheter infection.
- B4.7.4 Data on outcome analysis and cellular therapy product efficacy, including adverse events related to the recipient, donor, and/or product, shall be provided in a timely manner to entities involved in the collection, processing, and/or distribution of the cellular therapy product.
- B4.7.5 The Clinical Program should achieve one-year survival outcome within or above the expected range when compared to national or international outcome data.
- B4.7.5.1 If expected one-year survival outcome is not met, the Clinical Program shall submit a corrective action plan.
-
- B4.8 The Quality Management Plan shall include, or summarize and reference, policies, procedures, and a schedule for conducting, reviewing, and reporting audits of the Clinical Program's activities to verify compliance with elements of the Quality Management Program and operational policies and procedures.
- B4.8.1 Audits shall be conducted on a regular basis by an individual with sufficient expertise to identify problems, but who is not solely responsible for the process being audited.
 - B4.8.2 The results of audits shall be used to recognize problems, detect trends, identify improvement opportunities, implement corrective and preventive actions when necessary, and follow up on the effectiveness of these actions in a timely manner.
 - B4.8.3 Audits shall include, at a minimum:
 - B4.8.3.1 Periodic audit of the accuracy of clinical data.
 - B4.8.3.2 Annual audit of safety endpoints and immune effector cellular therapy toxicity management.

- B4.8.3.3 Periodic audit of the accuracy of data contained in the Transplant Essential Data Forms of the CIBMTR or the Minimum Essential Data-A Forms of the EBMT.
- B4.8.3.4 Annual audit of donor screening and testing.
- B4.8.3.5 Annual audit of verification of chemotherapy drug and dose against the prescription ordering system and the protocol.
- B4.8.3.6 Annual audit of management of cellular therapy products with positive microbial culture results.

B4.9 The Quality Management Plan shall include, or summarize and reference, policies and procedures on the management of cellular therapy products with positive microbial culture results that address at a minimum:

- B4.9.1 Notification of the recipient.
- B4.9.2 Recipient follow-up and outcome analysis.
- B4.9.3 Follow-up of the donor, if relevant.
- B4.9.4 Reporting to regulatory agencies if appropriate.
- B4.9.5 Criteria for the administration of cellular therapy products with positive microbial culture results.

B4.10 The Quality Management Plan shall include, or summarize and reference, policies and procedures for errors, accidents, biological product deviations, serious adverse events, and complaints, including the following activities at a minimum:

- B4.10.1 Detection.
- B4.10.2 Investigation.
 - B4.10.2.1 A thorough investigation shall be conducted by the Clinical Program in collaboration with the Collection Facility, Processing Facility, and other entities involved in the manufacture of the cellular therapy product, as appropriate.
 - B4.10.2.2 Investigations shall identify the root cause and a plan for short- and long-term corrective actions as warranted.
- B4.10.3 Documentation.

- B4.10.3.1 Documentation shall include a description of the event, the involved individuals and/or cellular therapy products, when the event occurred, when and to whom the event was reported, and the immediate actions taken.
 - B4.10.3.2 All investigation reports shall be reviewed in a timely manner by the Clinical Program Director or designee and the Quality Manager.
 - B4.10.3.3 Cumulative files of errors, accidents, biological product deviations, serious adverse events, and complaints shall be maintained.
 - B4.10.3.4 Cumulative files shall include written investigation reports containing conclusions, follow-up, corrective actions, and a link to the record(s) of the involved cellular therapy products, if applicable.
 - B4.10.4 Reporting.
 - B4.10.4.1 When it is determined that a cellular therapy product was responsible for an adverse reaction, the reaction and results of the investigation shall be reported to the recipient's physician, other facilities participating in the manufacturing of the cellular therapy product, registries, and governmental agencies as required by applicable laws and regulations.
 - B4.10.4.2 Errors, accidents, biological product deviations, and complaints shall be reported to other facilities performing cellular therapy product functions on the affected cellular therapy product and to the appropriate regulatory and accrediting agencies, registries, grant agencies, and IRBs or Ethics Committees.
 - B4.10.5 Corrective and preventive action.
 - B4.10.5.1 Appropriate corrective action shall be implemented if indicated, including both short-term action to address the immediate problem and long-term action to prevent the problem from recurring.
 - B4.10.5.2 Follow-up audits of the effectiveness of corrective actions shall be performed in a timeframe as indicated in the investigative report.
 - B4.10.6 There shall be a defined process to obtain feedback from patients or legally authorized representatives.
-
- B4.11 The Quality Management Plan shall include, or summarize and reference, policies and procedures for cellular therapy product tracking and tracing that allow tracking from the donor to the recipient or final disposition and tracing from the recipient or final disposition to the donor.
-
- B4.12 The Quality Management Plan shall include, or summarize and reference, policies and procedures for actions to take in the event the Clinical Program's operations are interrupted.

-
- B4.13 The Quality Management Plan shall include, or summarize and reference, policies and procedures for qualification of supplies and validation and/or verification of the procedure for marrow collection to achieve the expected end-points, including viability of cells and cellular therapy product characteristics.
- B4.13.1 Critical reagents, supplies, equipment, and facilities used for the marrow collection procedure shall be qualified.
- B4.13.1.1 Qualification plans shall be reviewed and approved by the Clinical Program Director or designee.
- B4.13.2 The marrow collection procedure validation shall include:
- B4.13.2.1 An approved validation plan, including conditions to be validated.
- B4.13.2.2 Acceptance criteria.
- B4.13.2.3 Data collection.
- B4.13.2.4 Evaluation of data.
- B4.13.2.5 Summary of results.
- B4.13.2.6 Review and approval of the validation plan, results, and conclusion by the Marrow Collection Facility Director or designee and the Quality Manager or designee.
- B4.13.3 Changes to a process with the potential to affect the potency, viability, or purity of the cellular therapy product shall include evaluation of risk that the change might create an adverse impact anywhere in the operation and shall be validated or verified as appropriate.
-

B5: POLICIES AND PROCEDURES

- B5.1 The Clinical Program shall establish and maintain policies and/or procedures addressing critical aspects of operations and management in addition to those required in B4. These documents shall include all elements required by these Standards and shall address at a minimum:
- B5.1.1 Recipient evaluation, selection, and treatment.
- B5.1.2 Donor and recipient confidentiality.
- B5.1.3 Donor and recipient consent.
- B5.1.4 Donor screening, testing, eligibility determination, selection, and management.

B5.1.5	Management of donors who require central venous access.
B5.1.6	Administration of the preparative regimen.
B5.1.7	Administration of blood products.
B5.1.8	Administration of HPC and other cellular therapy products, including products under exceptional release.
B5.1.9	Administration of ABO-incompatible products to include a description of the indication for and processing methods to be used for red cell or plasma reduction.
B5.1.10	Management of toxicities of immune effector cellular therapies, including cytokine release syndrome and central nervous system complications.
B5.1.11	Duration and conditions of cellular therapy product storage and indications for disposal.
B5.1.12	Hygiene and use of personal protective equipment.
B5.1.13	Disposal of medical and biohazard waste.
B5.1.14	Emergency and disaster plan, including the Clinical Program response.
B5.2	The Clinical Program shall maintain a detailed Standard Operating Procedures Manual that includes a listing of all current Standard Operating Procedures, including title, identifier, and version.
B5.3	Standard Operating Procedures shall be sufficiently detailed and unambiguous to allow qualified staff to follow and complete the procedures successfully. Each individual procedure shall include:
B5.3.1	A clearly written description of the objectives.
B5.3.2	A description of equipment and supplies used.
B5.3.3	Acceptable end-points and the range of expected results.
B5.3.4	A stepwise description of the procedure.
B5.3.5	Reference to other Standard Operating Procedures or policies required to perform the procedure.
B5.3.6	Age-specific issues where relevant.
B5.3.7	A reference section listing appropriate literature.

B5.3.8	Documented approval of each procedure by the Clinical Program Director or designated physician prior to implementation and every two years thereafter.
B5.3.9	Documented approval of each procedural modification by the Clinical Program Director or designated physician prior to implementation.
B5.3.10	Reference to a current version of orders, worksheets, reports, labels, and forms.
B5.4	Standard Operating Procedures relevant to processes being performed shall be readily available to the facility staff.
B5.5	Staff training and, if appropriate, competency shall be documented before performing a new or revised procedure.
B5.6	All personnel shall follow the Standard Operating Procedures related to their positions.
B5.7	Variances shall be pre-approved by the Clinical Program Director and reviewed by the Quality Manager.

B6: ALLOGENEIC AND AUTOLOGOUS DONOR SELECTION, EVALUATION, AND MANAGEMENT

B6.1	There shall be written criteria for allogeneic and autologous donor selection, evaluation, and management by trained medical personnel.
B6.1.1	Written criteria shall include criteria for the selection of allogeneic donors who are minors or elderly.
B6.1.2	Written criteria shall include criteria for the selection of allogeneic donors when more than one donor is available and suitable.
B6.1.3	Information regarding the donation process should be provided to the potential allogeneic donor prior to HLA typing.
B6.2	ALLOGENEIC AND AUTOLOGOUS DONOR INFORMATION AND CONSENT TO DONATE
B6.2.1	The collection procedure shall be explained in terms the donor can understand, and shall include the following information at a minimum:
B6.2.1.1	The risks and benefits of the procedure.

- B6.2.1.2 Tests and procedures performed on the donor to protect the health of the donor and the recipient.
 - B6.2.1.3 The rights of the donor or legally authorized representative to review the results of such tests according to applicable laws and regulations.
 - B6.2.1.4 Alternative collection methods.
 - B6.2.1.5 Protection of medical information and confidentiality.
 - B6.2.2 Interpretation and translation shall be performed by individuals qualified to provide these services in the clinical setting.
 - B6.2.3 Family members and legally authorized representatives should not serve as interpreters or translators.
 - B6.2.4 The donor shall have an opportunity to ask questions.
 - B6.2.5 The donor shall have the right to refuse to donate.
 - B6.2.5.1 The allogeneic donor shall be informed of the potential consequences to recipient of such refusal.
 - B6.2.6 Donor informed consent for the cellular therapy product donation shall be obtained and documented by a licensed health care professional familiar with the collection procedure.
 - B6.2.6.1 Informed consent from the allogeneic donor shall be obtained by a licensed health care professional who is not the primary health care professional overseeing care of the recipient.
 - B6.2.7 In the case of a minor donor, informed consent shall be obtained from the donor's legally authorized representative in accordance with applicable laws and regulations and shall be documented.
 - B6.2.8 The allogeneic donor shall give informed consent and authorization prior to release of the donor's health or other information to the recipient's physician and/or the recipient.
 - B6.2.9 The donor shall be informed of the policy for cellular therapy product discard or disposal, including actions taken when an intended recipient no longer requires the cellular therapy product.
 - B6.2.10 Documentation of consent shall be available to the Collection Facility staff prior to the collection procedure.
-
- B6.3 ALLOGENEIC AND AUTOLOGOUS DONOR SUITABILITY FOR CELLULAR THERAPY PRODUCT COLLECTION
- B6.3.1 There shall be criteria and evaluation policies and procedures in place to protect the safety of donors during the process of cellular therapy product collection.

- B6.3.1.1 Any abnormal finding shall be reported to the prospective donor with documentation in the donor record of recommendations made for follow-up care.
- B6.3.1.2 Allogeneic donor suitability shall be evaluated by a licensed health care professional who is not the primary health care professional overseeing care of the recipient.
- B6.3.1.3 Autologous donors shall be tested as required by applicable laws and regulations.
- B6.3.2 The risks of donation shall be evaluated and documented, including:
 - B6.3.2.1 Possible need for central venous access.
 - B6.3.2.2 Mobilization therapy for collection of HPC, Apheresis.
 - B6.3.2.3 Anesthesia for collection of HPC, Marrow.
- B6.3.3 The donor should be evaluated for the risk of hemoglobinopathy prior to administration of the mobilization regimen.
- B6.3.4 A pregnancy test shall be performed for all female donors with childbearing potential within seven (7) days prior to starting the donor mobilization regimen and, as applicable, within seven (7) days prior to the initiation of the recipient's preparative regimen.
- B6.3.5 Laboratory testing of all donors shall be performed by a laboratory that is accredited, registered, or licensed in accordance with applicable laws and regulations.
- B6.3.6 The Clinical Program shall inform the Collection Facility and Processing Facility of donor test results or if any testing was not performed.
- B6.3.7 There shall be a written order from a physician specifying, at a minimum, timing and goals of collection and processing.
- B6.3.8 Issues of donor health that pertain to the safety of the collection procedure shall be communicated in writing to the Collection Facility staff prior to collection.
- B6.3.9 Collection from a donor who does not meet Clinical Program collection safety criteria shall require documentation of the rationale for his/her selection by the recipient's physician.
- B6.3.10 There shall be a policy for follow-up of donors that includes routine management and the management of collection-associated adverse events.

B6.4 ADDITIONAL REQUIREMENTS FOR ALLOGENEIC DONORS

- B6.4.1 A donor advocate shall be available to represent allogeneic donors who are minors or who are mentally incapacitated, as those terms as defined by applicable laws.
- B6.4.2 Allogeneic donor infectious disease testing shall be performed using donor screening tests approved or cleared by the governmental authority.
- B6.4.3 Allogeneic donors and allogeneic recipients shall be tested for ABO group and Rh type using two independently collected samples. Discrepancies shall be resolved and documented prior to issue of the cellular therapy product.
- B6.4.4 A red cell antibody screen shall be performed on allogeneic recipients.
- B6.4.5 Allogeneic donors shall be evaluated for risk factors that might result in disease transmission from the cellular therapy product by medical history, physical examination, examination of relevant medical records, and laboratory testing.
- B6.4.6 The medical history for allogeneic donors shall include at least the following:
 - B6.4.6.1 Vaccination history.
 - B6.4.6.2 Travel history.
 - B6.4.6.3 Blood transfusion history.
 - B6.4.6.4 Questions to identify persons at high risk for transmission of communicable disease as defined by the applicable governmental authority.
 - B6.4.6.5 Questions to identify persons at risk of transmitting inherited conditions.
 - B6.4.6.6 Questions to identify persons at risk of transmitting a hematological or immunological disease.
 - B6.4.6.7 Questions to identify a past history of malignant disease.
 - B6.4.6.8 The allogeneic donor shall confirm that all the information provided is true to the best of his/her knowledge.
- B6.4.7 Allogeneic donors shall be tested for evidence of clinically relevant infection by the following communicable disease agents using tests required by applicable laws and regulations:
 - B6.4.7.1 Human immunodeficiency virus, type 1.
 - B6.4.7.2 Human immunodeficiency virus, type 2.
 - B6.4.7.3 Hepatitis B virus.
 - B6.4.7.4 Hepatitis C virus.
 - B6.4.7.5 *Treponema pallidum* (syphilis).

- B6.4.8 If required by applicable laws and regulations, allogeneic donors shall also be tested for evidence of clinically relevant infection by the following disease agents:
- B6.4.8.1 Human T cell lymphotropic virus I.
 - B6.4.8.2 Human T cell lymphotropic virus II.
 - B6.4.8.3 West Nile Virus.
 - B6.4.8.4 *Trypanosoma cruzi* (Chagas Disease).
- B6.4.9 Blood samples for testing for evidence of clinically relevant infection shall be drawn and tested within timeframes required by applicable laws and regulations.
- B6.4.9.1 Blood samples for communicable disease testing from allogeneic HPC donors shall be obtained within thirty (30) days prior to collection.
 - B6.4.9.2 For viable, lymphocyte rich cells, including mononuclear cells and other cellular therapy products, blood samples from allogeneic donors shall be obtained within seven (7) days prior to or after collection in the U.S. or 30 days prior to collection in European Union member states.
- B6.4.10 Allogeneic donors shall be tested for CMV (unless previously documented to be positive).
- B6.4.11 Additional tests shall be performed as required to assess the possibility of transmission of other infectious and non-infectious diseases.
- B6.4.12 Allogeneic donors and recipients shall be tested for HLA antigens by a laboratory accredited by ASHI, EFI, or other appropriate organization. Typing shall include at a minimum HLA-A, B, and DRB1 type for all allogeneic donors and also HLA-C type for unrelated allogeneic donors and related allogeneic donors other than siblings.
- B6.4.12.1 DNA high resolution molecular typing shall be used for DRB1 typing.
 - B6.4.12.2 Verification typing shall be performed on the selected allogeneic donor using an independently collected sample. Results shall be confirmed prior to administration of the preparative regimen.
 - B6.4.12.3 There shall be a procedure to confirm the identity of cord blood units if verification typing cannot be performed on attached segments.
 - B6.4.12.4 There shall be a policy for anti-HLA antibody testing for mismatched donors and recipients.
- B6.4.13 Allogeneic donor eligibility, as defined by applicable laws and regulations, shall be determined by a physician after history, exam, medical record review, and testing. The donor eligibility determination shall be documented in the recipient's medical record before the recipient's preparative regimen is initiated and before the allogeneic donor begins the mobilization regimen.
- B6.4.14 Records required for donor eligibility determination shall be in English or translated into English when crossing international borders.

- B6.4.15 The use of an ineligible allogeneic donor, or an allogeneic donor for whom donor eligibility determination is incomplete, shall require documentation of the rationale for his/her selection by the transplant physician, urgent medical need documentation, and the informed consent of the donor and the recipient.
- B6.4.16 Allogeneic donor eligibility shall be communicated in writing to the Collection and Processing Facilities.
- B6.4.17 There shall be a policy covering the creation and retention of allogeneic donor records.
 - B6.4.17.1 Allogeneic donor records shall include donor eligibility determination, including the name of the responsible person who made the determination and the date of the determination.

B7: RECIPIENT CARE

- B7.1 Recipient informed consent for the cellular therapy shall be obtained and documented by a licensed health care professional familiar with the proposed therapy.
 - B7.1.1 The Clinical Program shall provide information regarding the risks and benefits of the proposed cellular therapy.
- B7.2 The attending physician shall verify the availability and suitability of a donor or cellular therapy product prior to initiating the recipient's preparative regimen.
 - B7.2.1 The Clinical Program shall notify the Processing Facility prior to requesting a cellular therapy product from a cord blood bank, registry, or other facility.
- B7.3 Records shall be made concurrently with each step of recipient care in such a way that all steps may be accurately traced.
 - B7.3.1 Records shall identify the person immediately responsible for each significant step, including dates and times (where appropriate) of various steps.
- B7.4 There shall be a policy addressing safe administration of the preparative regimen.
 - B7.4.1 The treatment orders shall include the patient height and weight, specific dates of administration, daily doses (if appropriate), and route of administration of each agent.

- B7.4.2 Preprinted orders or electronic equivalent shall be used for protocols and standardized regimens. These orders shall be verified and documented by an attending physician.
- B7.4.3 The pharmacist preparing the drug shall verify and document the doses against the protocol or standardized regimen listed on the orders.
- B7.4.4 Prior to administration of the preparative regimen, one (1) qualified person using a validated process or two (2) qualified people shall verify and document the drug and dose in the bag or pill against the orders and the protocol, and the identity of the patient to receive the therapy.
-
- B7.5 There shall be a policy addressing safe administration of radiation therapy.
- B7.5.1 There shall be a consultation with a radiation oncologist prior to initiation of therapy if radiation treatment is used in the preparative regimen.
- B7.5.2 The patient's diagnosis, relevant medical history including pre-existing co-morbid conditions, and proposed preparative regimen shall be made available to the consulting radiation oncologist in writing.
- B7.5.3 A documented consultation by a radiation oncologist shall address any prior radiation treatment the patient may have received, any other factors that may increase the toxicity of the radiation, and include a plan for delivery of radiation therapy.
- B7.5.4 Prior to administration of each dose of radiation therapy, the dose shall be verified and documented as per radiation therapy standards.
- B7.5.5 A final report of the details of the radiation therapy administered shall be documented in the patient medical record.
-
- B7.6 There shall be a policy addressing safe administration of cellular therapy products.
- B7.6.1 There shall be a policy for determining the appropriate volume and the appropriate dose of red blood cells, cryoprotectants, and other additives.
- B7.6.2 There shall be a policy for volume of ABO-incompatible red cells in allogeneic cellular therapy products.
- B7.6.3 There shall be consultation with the Processing Facility regarding cord blood preparation for administration.
- B7.6.3.1 Cord blood units that have not been red cell reduced prior to cryopreservation shall be washed prior to administration.
- B7.6.3.2 Cord blood units that have been red cell reduced prior to cryopreservation should be diluted or washed prior to administration.

-
- B7.6.4 Two (2) qualified persons shall verify the identity of the recipient and the product and the order for administration prior to the administration of the cellular therapy product.
- B7.6.5 For transplants utilizing cellular therapy products from more than one donor, the first cellular therapy product shall be administered safely prior to administration of the second cellular therapy product.
- B7.6.6 There shall be documentation in the recipient's medical record of the administered cellular therapy product unique identifier, initiation and completion times of administration, and any adverse events related to administration.
- B7.6.7 A circular of information for cellular therapy products shall be available to staff.
- B7.6.8 There should be policies and procedures in place for monitoring by appropriate specialists of recipients for post-transplant late effects, including at a minimum endocrine and reproductive function, osteoporosis, cardiovascular risk factors, respiratory function, chronic renal impairment, secondary cancers, and the growth and development of pediatric patients.
-
- B7.7 ADDITIONAL REQUIREMENTS FOR ALLOGENEIC TRANSPLANTATION
- B7.7.1 Allogeneic recipients should be assessed regularly for evidence of acute GVHD using an established staging and grading system.
- B7.7.2 Allogeneic recipients should be assessed regularly for evidence of chronic GVHD using an established staging and grading system.
- B7.7.3 There should be policies and procedures in place for allogeneic recipient post-transplant vaccination schedules and indications.
-
- B7.8 The Clinical Program shall refer planned discharges and post-transplant care to facilities and health care professionals adequate for post-transplant care.
- B7.8.1 The Clinical Program shall provide or secure oversight of care that meets applicable standards.
-
- B7.9 There shall be a policy addressing indications for and safe administration of ECP if utilized by the Clinical Program.
- B7.9.1 There shall be a consultation with the facility or physician that performs ECP prior to initiation of therapy.
- B7.9.2 Before ECP is undertaken, there shall be a written therapy plan from an attending physician specifying the patient's diagnosis and GVHD grade, involved organs, timing of the procedure, and any other factors that may affect the safe administration of ECP.
-

- B7.9.3 A report of the details of ECP administered, including an assessment of the response, shall be documented in the recipient's medical record.
- B7.9.4 The facility performing ECP shall follow written procedures appropriate for the clinical condition of the patient.
-
- B7.10 There shall be policies and procedures addressing the administration of immune effector cells and management of complications.
- B7.10.1 There shall be a consultation with the referring physician prior to initiation of immune effector cellular therapy to review the goal and plan of the treatment.
- B7.10.2 There shall be regular assessment of the recipient to detect complications, including cytokine release syndrome and neurologic dysfunction.
- B7.10.3 There shall be a written plan for rapid escalation of care, increased intensity of monitoring, and relevant workup to address complications.
- B7.10.4 Communication to the clinical staff, intensive care unit, emergency department, and pharmacy shall be timely.
- B7.10.5 The Clinical Program shall have written guidelines for management of complications, including the use of cytokine-blocking agents and corticosteroid administration.
-

B8: CLINICAL RESEARCH

- B8.1 Clinical Programs shall have formal review of investigational treatment protocols and patient consent forms by a process that is approved under institutional policies and applicable laws and regulations.
- B8.1.1 Those Clinical Programs utilizing investigational treatment protocols shall have in place a pharmacy equipped for research activities, including a process for tracking, inventory, and secured storage of investigational drugs.
- B8.1.2 There shall be a process to manage investigational cellular therapy products.
-
- B8.2 Documentation for all research protocols performed by the Clinical Program shall be maintained in accordance with institutional policies and applicable laws and regulations, including audits; approvals by the Institutional Review Board, Ethics Committee, or equivalent; correspondence with regulatory agencies; and any adverse events.
-

- B8.3 For clinical research, informed consent shall be obtained from each research subject or legally authorized representative, in language he or she can understand, and under circumstances that minimize the possibility of coercion or undue influence.
- B8.3.1 The research subject or legally authorized representative shall be given the opportunity to ask questions and to have his/her questions answered to his/her satisfaction, and to withdraw from the research without prejudice.
- B8.3.2 Informed consent for a research subject shall contain the following elements at a minimum and comply with applicable laws and regulations:
- B8.3.2.1 An explanation of the research purposes, a description of the procedures to be followed, and the identification of investigational procedures.
- B8.3.2.2 The expected duration of the subject's participation.
- B8.3.2.3 A description of the reasonably expected risks, discomforts, benefits to the subject and others, and alternative procedures.
- B8.3.2.4 A statement of the extent to which confidentiality will be maintained.
- B8.3.2.5 An explanation of the extent of compensation for injury.
-
- B8.4 There shall be a process in place to address the disclosure of any issues that may represent a conflict of interest in clinical research.
-

B9: DATA MANAGEMENT

- B9.1 The Clinical Program shall collect all the data necessary to complete the Transplant Essential Data Forms of the CIBMTR or the Minimum Essential Data-A forms of the EBMT.
- B9.1.1 Clinical Programs shall submit the data specified in B9.1 to a national or international database if required by applicable laws and regulations.
- B9.1.2 Clinical Programs should submit the data specified in B9.1 for allogeneic and autologous transplants to a national or international database.
- B9.1.3 Clinical Programs should collect the data specified in B9.1 for all patients for at least one year following administration of the cellular therapy product.
- B9.2 The Clinical Program should collect all the data elements included in the applicable CIBMTR Cellular Therapy forms or EBMT forms.
- B9.3 The Clinical Program shall define staff responsible for collecting data and, as appropriate, reporting data to institutional repositories and CIBMTR or EBMT.

B10: RECORDS

B10.1 Clinical Program records related to quality control, personnel training and competency, facility maintenance, facility management, complaints, or other general facility issues shall be retained for a minimum of ten (10) years by the Clinical Program, or longer in accordance with applicable laws and regulations, or by a defined program or institutional policy.

B10.1.1 Employee records shall be maintained in a confidential manner and as required by applicable laws and regulations.

B10.2 Patient and donor records including, but not limited to, consents and records of care, shall be maintained in a confidential manner as required by applicable laws and regulations for a minimum of ten (10) years after the administration of the cellular therapy product, or, if not known, ten (10) years after the date of the distribution, disposition, or expiration, whichever requires the longest maintenance period.

B10.3 Research records shall be maintained in a confidential manner as required by applicable laws and regulations for a minimum of ten (10) years after the administration, distribution, disposition, or expiration of the cellular therapy product, whichever is latest.

B10.4 RECORDS IN CASE OF DIVIDED RESPONSIBILITY

B10.4.1 If two (2) or more facilities participate in the collection, processing, or administration of the cellular therapy product, the records of each facility shall show plainly the extent of its responsibility.

B10.4.2 The Clinical Program shall furnish outcome data, in so far as they concern the safety, purity, or potency of the cellular therapy product involved, to other facilities involved in the collection or processing of the cellular therapy product.

MARROW COLLECTION FACILITY STANDARDS**PART CM**

CM1	General
CM2	Marrow Collection Facility
CM3	Personnel
CM4	Quality Management
CM5	Policies and Procedures
CM6	Allogeneic and Autologous Donor Evaluation and Management
CM7	Coding and Labeling of Cellular Therapy Products
CM8	Process Controls
CM9	Cellular Therapy Product Storage
CM10	Cellular Therapy Product Transportation and Shipping
CM11	Records
CM12	Direct Distribution to Clinical Program

PART CM: MARROW COLLECTION FACILITY STANDARDS**CM1: GENERAL**

CM1.1 These Standards apply to the Marrow Collection Facility for collection activities of all cellular therapy products collected from living donors.

CM1.2 The Marrow Collection Facility shall use cell processing facilities that meet FACT-JACIE Standards with respect to their interactions with the Marrow Collection Facility.

CM1.3 The Marrow Collection Facility shall abide by all applicable laws and regulations.

CM1.3.1 The Marrow Collection Facility shall be licensed, registered, or accredited as required by the appropriate governmental authorities for the activities performed.

CM1.4 The Marrow Collection Facility shall have a Marrow Collection Facility Medical Director, a Quality Manager, and at least one (1) additional designated staff member. This team shall have been in place and performing cellular therapy product collections for at least twelve (12) months preceding initial accreditation.

CM1.5 A minimum of one (1) marrow collection procedure shall have been performed in the twelve (12) month period immediately preceding facility accreditation, and a minimum average of one (1) marrow collection procedure per year shall be performed within the accreditation cycle.

CM2: MARROW COLLECTION FACILITY

CM2.1 There shall be appropriate designated areas for collection of cellular therapy products, for collected products, and for storage of supplies, reagents, and equipment.

CM2.1.1 The Marrow Collection Facility shall be divided into defined areas of adequate size to prevent improper labeling, mix-ups, contamination, or cross-contamination of cellular therapy products.

CM2.1.2 There shall be a process to control storage areas to prevent mix-ups, contamination, and cross-contamination of all cellular therapy products prior to release or distribution.

CM2.1.3 There shall be a process for confidential donor examination and evaluation.

*FACT-JACIE International Standards
Sixth Edition – Version 6.1*

-
- CM2.2 The Marrow Collection Facility shall provide adequate lighting, ventilation, and access to sinks to prevent the introduction, transmission, or spread of communicable disease.
-
- CM2.3 Critical Marrow Collection Facility parameters that may affect cellular therapy product viability, integrity, contamination, sterility, or cross-contamination during collection, including temperature and humidity at a minimum, shall be assessed for risk to the cellular therapy product.
- CM2.3.1 Critical facility parameters identified to be a risk to the cellular therapy product shall be controlled, monitored, and recorded.
-
- CM2.4 Marrow Collection Facility parameters and environmental conditions shall be controlled to protect the safety and comfort of patients, donors, and personnel.
-
- CM2.5 The Marrow Collection Facility shall document facility cleaning and sanitation and maintain order sufficient to achieve adequate conditions for operations.
-
- CM2.6 There shall be adequate equipment and materials for the procedures performed.
-
- CM2.7 There shall be access to an intensive care unit and/or emergency services.
-
- CM2.8 The Marrow Collection Facility shall be operated in a manner designed to minimize risks to the health and safety of employees, patients, donors, visitors, and volunteers.
-
- CM2.9 The Marrow Collection Facility shall have a written safety manual that includes instructions for action in case of exposure, as applicable, to communicable disease and to chemical, biological, or radiological hazards.
-

CM3: PERSONNEL

CM3.1 MARROW COLLECTION FACILITY MEDICAL DIRECTOR

- CM3.1.1 There shall be a Marrow Collection Facility Medical Director who is a licensed physician with postgraduate training in cell collection and/or transplantation.
- CM3.1.2 The Marrow Collection Facility Medical Director or designee shall be responsible for the following elements:
 - CM3.1.2.1 All technical procedures.
 - CM3.1.2.2 Performance of the marrow collection procedure.
 - CM3.1.2.3 Supervision of staff.
 - CM3.1.2.4 Administrative operations.
 - CM3.1.2.5 The medical care of allogeneic and/or autologous donors undergoing marrow collection.
 - CM3.1.2.6 Pre-collection evaluation of allogeneic and/or autologous donors at the time of donation.
 - CM3.1.2.7 Care of any complications resulting from the collection procedure.
 - CM3.1.2.8 The Quality Management Program, including compliance with these Standards and other applicable laws and regulations.
- CM3.1.3 The Marrow Collection Facility Medical Director shall have at least one year experience in cellular therapy product collection procedures.
- CM3.1.4 The Marrow Collection Facility Medical Director shall have performed or supervised at least ten (10) marrow collection procedures within his/her career.
- CM3.1.5 The Marrow Collection Facility Medical Director shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
 - CM3.1.5.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation and marrow collection.

CM3.2 QUALITY MANAGER

- CM3.2.1 There shall be a Marrow Collection Facility Quality Manager to establish and maintain systems to review, modify, and approve all policies and procedures intended to monitor compliance with these Standards and/or the performance of the Marrow Collection Facility.

CM3.2.2 The Marrow Collection Facility Quality Manager shall participate in ten (10) hours of educational activities related to cellular therapy, cell collection, and/or quality management annually at a minimum.

CM3.2.2.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation.

CM3.3 STAFF

CM3.3.1 The Marrow Collection Facility shall have access to licensed health care professionals who are trained and competent in marrow collection.

CM3.3.2 The number of trained collection personnel shall be adequate for the number of procedures performed and shall include a minimum of one designated trained individual with an identified trained backup to maintain sufficient coverage.

CM3.3.3 For Marrow Collection Facilities collecting cellular therapy products from pediatric donors, physicians and collection staff shall have documented training and experience in performing these procedures.

CM4: QUALITY MANAGEMENT

CM4.1 The Marrow Collection Facility shall comply with B4 if it operates independently of a Clinical Program.

CM5: POLICIES AND PROCEDURES

CM5.1 The Marrow Collection Facility shall establish and maintain policies and/or procedures addressing critical aspects of operations and management in addition to those required in CM4. These documents shall include all elements required by these Standards and shall address at a minimum:

CM5.1.1 Donor and recipient confidentiality.

CM5.1.2 Donor consent.

CM5.1.3 Donor screening, testing, eligibility determination, and management.

CM5.1.4 Cellular therapy product collection.

CM5.1.5 Prevention of mix-ups and cross-contamination.

CM5.1.6 Labeling (including associated forms and samples).

-
- CM5.1.7 Cellular therapy product expiration dates.
 - CM5.1.8 Cellular therapy product storage.
 - CM5.1.9 Release and exceptional release.
 - CM5.1.10 Transportation and shipping, including methods and conditions to be used for distribution to external facilities.
 - CM5.1.11 Critical equipment, reagent, and supply management including recalls and corrective actions in the event of failure.
 - CM5.1.12 Hygiene and use of personal protective attire.
 - CM5.1.13 Emergency and disaster plan related to the marrow collection procedure.
-
- CM5.2 The Marrow Collection Facility shall comply with B5.2 if it operates independently of a Clinical Program.
-
- CM5.3 Standard Operating Procedures required in CM5.1 shall be sufficiently detailed and unambiguous to allow qualified staff to follow and complete the procedures successfully. Each individual procedure shall include:
- CM5.3.1 A clearly written description of the objectives.
 - CM5.3.2 A description of equipment and supplies used.
 - CM5.3.3 Acceptable end-points and the range of expected results.
 - CM5.3.4 A stepwise description of the procedure.
 - CM5.3.5 Age-specific issues where relevant.
 - CM5.3.6 Reference to other Standard Operating Procedures or policies required to perform the procedure.
 - CM5.3.7 A reference section listing appropriate literature.
 - CM5.3.8 Documented approval of each procedure by the Marrow Collection Facility Medical Director prior to implementation and every two years thereafter.
 - CM5.3.9 Documented approval of each procedural modification by the Marrow Collection Facility Medical Director or designated physician prior to implementation.
 - CM5.3.10 Reference to a current version of orders, worksheets, reports, labels, and forms.
-

- CM5.4 Standard Operating Procedures relevant to processes being performed shall be readily available to the facility staff.
-
- CM5.5 Staff training and, if appropriate, competency shall be documented before performing a new or revised procedure.
-
- CM5.6 All personnel shall follow the Standard Operating Procedures related to their positions.
-
- CM5.7 Variances shall be pre-approved by the Marrow Collection Facility Medical Director, and reviewed by the Quality Manager.
-

CM6: ALLOGENEIC AND AUTOLOGOUS DONOR EVALUATION AND MANAGEMENT

- CM6.1 There shall be written criteria for allogeneic and autologous donor evaluation and management by trained medical personnel.
-
- CM6.2 ALLOGENEIC AND AUTOLOGOUS DONOR INFORMATION AND CONSENT FOR COLLECTION
- CM6.2.1 The collection procedure shall be explained in terms the donor can understand, and shall include the following information at a minimum:
- CM6.2.1.1 The risks and benefits of the procedure.
- CM6.2.1.2 Tests and procedures performed on the donor to protect the health of the donor and the recipient.
- CM6.2.1.3 The rights of the donor or legally authorized representative to review the results of such tests according to applicable laws and regulations.
- CM6.2.1.4 Protection of medical information and confidentiality.
- CM6.2.2 Interpretation and translation shall be performed by individuals qualified to provide these services in the clinical setting.
- CM6.2.3 Family members and legally authorized representatives should not serve as interpreters or translators.
- CM6.2.4 The donor shall have an opportunity to ask questions.
- CM6.2.5 The donor shall have the right to refuse to donate.
-

- CM6.2.5.1 The allogeneic donor shall be informed of the potential consequences to recipient of such refusal.
- CM6.2.6 Donor informed consent for the cellular therapy product collection shall be obtained and documented by a licensed health care professional familiar with the collection procedure.
- CM6.2.6.1 Informed consent from the allogeneic donor shall be obtained by a licensed health care professional who is not the primary health care professional overseeing care of the recipient.
- CM6.2.7 In the case of a minor donor, informed consent shall be obtained from the donor's legally authorized representative in accordance with applicable laws and regulations and shall be documented.
- CM6.2.8 The allogeneic donor shall give informed consent and authorization prior to release of the donor's health or other information to the recipient's physician and/or the recipient.
- CM6.2.9 Documentation of consent shall be available to the Marrow Collection Facility staff prior to the collection procedure.
-
- CM6.3 ALLOGENEIC AND AUTOLOGOUS DONOR SUITABILITY FOR CELLULAR THERAPY PRODUCT COLLECTION
- CM6.3.1 There shall be criteria and evaluation policies and procedures in place to protect the safety of donors during the process of cellular therapy product collection.
- CM6.3.1.1 The Marrow Collection Facility shall confirm that any abnormal findings are reported to the prospective donor with documentation in the donor record of recommendations made for follow-up care.
- CM6.3.1.2 Allogeneic donor suitability shall be evaluated by a licensed health care professional who is not the primary health care professional overseeing care of the recipient.
- CM6.3.1.3 Autologous donors shall be tested as required by applicable laws and regulations.
- CM6.3.2 The risks of donation shall be evaluated and documented, including anesthesia for marrow collection.
- CM6.3.3 A pregnancy test shall be performed for all female donors with childbearing potential within seven (7) days prior to starting the donor mobilization regimen and, as applicable, within seven (7) days prior to the initiation of the recipient's preparative regimen.
- CM6.3.4 Laboratory testing of all donors shall be performed by a laboratory that is accredited, registered, or licensed in accordance with applicable laws and regulations.

- CM6.3.5 The Clinical Program shall inform the Collection Facility and Processing Facility of donor test results or if any testing was not performed.
- CM6.3.6 There shall be a written order from a physician specifying, at a minimum, timing and goals of collection.
- CM6.3.7 Collection from a donor who does not meet Clinical Program collection safety criteria shall require documentation of the rationale for his/her selection by the transplant physician. Collection staff shall document review of these donor safety issues.
- CM6.3.8 There shall be written documentation of issues of donor health that pertain to the safety of the collection procedure available to the Marrow Collection Facility staff. Collection staff shall document review of these issues prior to collection.
- CM6.3.9 There shall be a policy for follow-up of donors that includes routine management and the management of collection-associated adverse events.

CM6.4 ADDITIONAL REQUIREMENTS FOR ALLOGENEIC DONORS

- CM6.4.1 A donor advocate shall be available to represent allogeneic donors who are minors or who are mentally incapacitated.
- CM6.4.2 Allogeneic donor infectious disease testing shall be performed using donor screening tests approved or cleared by the governmental authority.

CM7: CODING AND LABELING OF CELLULAR THERAPY PRODUCTS

CM7.1 ISBT 128 CODING AND LABELING

- CM7.1.1 Cellular therapy products shall be identified according to the proper name of the product, including appropriate attributes, as defined in ISBT 128 Standard Terminology for Blood, Cellular Therapy, and Tissue Product Descriptions.
- CM7.1.2 If coding and labeling technologies have not yet been implemented, the Marrow Collection Facility shall be actively implementing ISBT 128.

CM7.2 LABELING OPERATIONS

- CM7.2.1 Labeling operations shall be conducted in a manner adequate to prevent mislabeling or misidentification of cellular therapy products, product samples, and associated records.
 - CM7.2.1.1 Stocks of unused labels representing different products shall be stored in a controlled manner to prevent errors.

- CM7.2.1.2 Obsolete labels shall be restricted from use.
- CM7.2.2 Pre-printed labels shall be held upon receipt from the manufacturer pending review and proofing against a copy or template approved by the Marrow Collection Facility Medical Director or designee to confirm accuracy regarding identity, content, and conformity.
- CM7.2.3 Print-on-demand label systems shall be validated to confirm accuracy regarding identity, content, and conformity of labels to templates approved by the Marrow Collection Facility Medical Director or designee.
- CM7.2.4 A system for label version control shall be employed.
- CM7.2.4.1 Representative obsolete labels shall be archived minimally for ten (10) years after the last cellular therapy product was distributed with inclusive dates of use or as defined by applicable laws and regulations, whichever is longer.
- CM7.2.5 A system of checks in labeling procedures shall be used to prevent errors in transferring information to labels.
- CM7.2.5.1 Cellular therapy products that are subsequently re-packaged into new containers shall be labeled with new labels before they are detached from the original container.
- CM7.2.5.2 A controlled labeling procedure consistent with applicable law shall be defined and followed if container label information is transmitted electronically during a labeling process. This procedure shall include a verification step.
- CM7.2.6 When the label has been affixed to the container, a sufficient area of the container shall remain uncovered to permit inspection of the contents.
- CM7.2.7 The information entered on a container label shall be verified by one (1) qualified staff member using a validated process to verify the information or two (2) qualified staff members.
- CM7.2.8 Labeling elements required by applicable laws and regulations shall be present.
- CM7.2.9 All data fields on labels shall be completed.
- CM7.2.10 All labeling shall be clear, legible, and completed using ink that is indelible to all relevant agents.
- CM7.2.11 Labels affixed directly to a cellular therapy product bag shall be applied using appropriate materials as defined by the applicable regulatory authority.
- CM7.2.12 The label shall be validated as reliable for storage under the conditions in use.

CM7.3 PRODUCT IDENTIFICATION

- CM7.3.1 Each cellular therapy product collection shall be assigned a unique numeric or alphanumeric identifier by which it will be possible to trace any cellular therapy product to its donor, its recipient or final disposition, and all records.
- CM7.3.1.1 The cellular therapy product, product samples, and concurrently collected samples shall be labeled with the same identifier.
- CM7.3.1.2 If a single cellular therapy product is stored in more than one container, there shall be a system to identify each container.
- CM7.3.1.3 Supplementary identifiers shall not obscure the original identifier.
- CM7.3.1.4 The facility associated with each identifier shall be noted on the label.

CM7.4 LABEL CONTENT

- CM7.4.1 At the end of the cellular therapy product collection, the cellular therapy product label on the primary product container shall bear the information in the Cellular Therapy Product Labeling table in Appendix II.
- CM7.4.2 Each label shall bear the appropriate biohazard and warning labels as found in the Circular of Information (COI) for the Use of Cellular Therapy Products, "Table 2. Biohazard and Warning Labels on Cellular Therapy Products Collected, Processed, and/or Administered in the United States."
- CM7.4.3 Labeling at the end of collection shall occur before the cellular therapy product bag is removed from the proximity of the donor.
- CM7.4.4 Cellular therapy products collected in or designated for use in the U.S. shall be accompanied by the elements listed in the Accompanying Documents at Distribution table in Appendix IV at the time of distribution.
- CM7.4.5 For cellular therapy products distributed before completion of donor eligibility determination, there shall be documentation that donor eligibility determination was completed during or after the use of the product.
- CM7.4.6 Cellular therapy products distributed for nonclinical purposes shall be labeled with the statement, "For Nonclinical Use Only."

CM8: PROCESS CONTROLS

- CM8.1 Collection of cellular therapy products shall be performed according to written collection procedures.

- CM8.2 There shall be a process for inventory control that encompasses equipment, reagents, supplies, and labels.
- CM8.2.1 There shall be a system to uniquely identify and track and trace all critical equipment, reagents, supplies, and labels used in the collection of cellular therapy products.
- CM8.2.2 Each supply and reagent used to collect cellular therapy products shall be visually examined at receipt and prior to use for damage or evidence of contamination.
- CM8.2.3 Supplies and reagents coming into contact with cellular therapy products during collection shall be sterile and of the appropriate grade for the intended use.
-
- CM8.3 Equipment for the marrow collection procedure shall conform to applicable laws and regulations.
-
- CM8.4 Autologous and/or CMV-appropriate and irradiated blood components shall be available during the marrow collection procedure for all donors.
-
- CM8.5 Before cell collection is undertaken, there shall be a written order from a physician specifying, at a minimum, timing and goals of collection.
-
- CM8.6 There shall be peripheral blood count criteria to proceed with collection.
-
- CM8.7 There shall be written documentation of an assessment of donor suitability for the collection procedure performed by a qualified person immediately prior to each collection procedure.
-
- CM8.8 General or regional anesthesia, if required, shall be performed or supervised by a licensed, specialist-certified anesthesiologist.
-
- CM8.9 Administration of mobilization agents shall be under the supervision of a licensed health care professional experienced in their administration and management of complications in persons receiving these agents.
-

CM8.10 The Marrow Collection Facility shall utilize a process for assessing the quality of cellular therapy products to confirm product safety, viability, and integrity and to document that products meet predetermined release specifications. Results of all such assessments shall become part of the permanent record of the product collected.

CM8.10.1 Methods for collection shall include a process for controlling and monitoring the collection of cellular therapy products to confirm products meet predetermined release specifications.

CM8.10.2 Methods for collection shall employ procedures validated to result in acceptable cell viability and recovery.

CM8.11 Collection methods shall employ aseptic technique so that cellular therapy products do not become contaminated during collection.

CM8.12 Collection methods for pediatric donors shall employ appropriate age and size adjustments to the procedures.

CM8.13 Cellular therapy products shall be packaged in a closed sterile transfer pack appropriate for blood or marrow products.

CM8.14 HPC, Marrow products shall be filtered to remove particulate material prior to final packaging, distribution, or administration using filters that are non-reactive with blood.

CM8.15 Records shall be made concurrently with each step of collection of each cellular therapy product in such a way that all steps may be accurately traced.

CM8.15.1 Records shall identify the person immediately responsible for each significant step, including dates and times, where appropriate.

CM9: CELLULAR THERAPY PRODUCT STORAGE

CM9.1 Marrow Collection Facilities shall control storage areas to prevent mix-ups, deterioration, contamination, cross-contamination, and improper release or distribution of products.

CM9.2 Marrow Collection Facilities shall establish policies for the duration and conditions of short-term storage prior to distribution to a Processing Facility or Clinical Program.

CM10: CELLULAR THERAPY PRODUCT TRANSPORTATION AND SHIPPING

CM10.1 Procedures for transportation and shipping of the cellular therapy product shall be designed to protect the integrity of the product and the health and safety of individuals in the immediate area.

CM10.2 The primary cellular therapy product container shall be placed in a secondary container that is sealed to prevent leakage.

CM10.3 The cellular therapy product shall be transported and/or shipped to the Processing Facility in a validated container at a temperature defined in a Standard Operating Procedure.

CM10.3.1 Cellular therapy products that are transported and/or shipped from the collection site to the Processing Facility shall be transported and/or shipped in an outer container made of material adequate to withstand leakage of contents, impact shocks, pressure changes, temperature changes, puncture, and other conditions incident to ordinary handling.

CM10.3.2 If the intended recipient has received high-dose therapy, the cellular therapy product shall be transported.

CM10.4 The cellular therapy product shall be transported and/or shipped with required accompanying records as defined in the transportation and shipping procedure and in compliance with CM7.4.4 and CM7.4.5.

CM10.5 There shall be a record of the date and time of cellular therapy product distribution.

CM11: RECORDS

CM11.1 The Marrow Collection Facility shall comply with B10 if it operates independently of a Clinical Program.

CM12: DIRECT DISTRIBUTION TO CLINICAL PROGRAM

- CM12.1 Where cellular therapy products are distributed directly from the Marrow Collection Facility to the Clinical Program for administration or subsequent processing, the Standards related to labeling, documentation, distribution, transportation, and recordkeeping in Sections D7, D10, D11, D13, and the Appendices apply.

APHERESIS COLLECTION FACILITY STANDARDS**PART C**

- C1 General
- C2 Apheresis Collection Facility
- C3 Personnel
- C4 Quality Management
- C5 Policies and Procedures
- C6 Allogeneic and Autologous Donor Evaluation and Management
- C7 Coding and Labeling of Cellular Therapy Products
- C8 Process Controls
- C9 Cellular Therapy Product Storage
- C10 Cellular Therapy Product Transportation and Shipping
- C11 Records
- C12 Direct Distribution to Clinical Program

PART C: APHERESIS COLLECTION FACILITY STANDARDS**C1: GENERAL**

-
- C1.1 These Standards apply to the Apheresis Collection Facility for collection activities of all cellular therapy products collected from living donors.
-
- C1.2 The Apheresis Collection Facility shall use cell processing facilities that meet FACT-JACIE Standards with respect to their interactions with the Apheresis Collection Facility.
-
- C1.3 The Apheresis Collection Facility shall abide by all applicable laws and regulations.
- C1.3.1 The Apheresis Collection Facility shall be licensed, registered, or accredited as required by the appropriate governmental authorities for the activities performed.
-
- C1.4 The Apheresis Collection Facility shall have an Apheresis Collection Facility Director, an Apheresis Collection Facility Medical Director, a Quality Manager, and at least one (1) additional designated staff member. This team shall have been in place and performing cellular therapy product collections for at least twelve (12) months preceding initial accreditation.
-
- C1.5 A minimum of ten (10) cellular therapy products shall have been collected by apheresis in the twelve (12) month period immediately preceding facility accreditation, and a minimum average of ten (10) cellular therapy products shall have been collected by apheresis per year within the accreditation cycle.
-

C2: APHERESIS COLLECTION FACILITY

-
- C2.1 There shall be appropriate designated areas for collection of cellular therapy products, for collected products, and for storage of supplies, reagents, and equipment.
- C2.1.1 The Apheresis Collection Facility shall be divided into defined areas of adequate size to prevent improper labeling, mix-ups, contamination, or cross-contamination of cellular therapy products.
- C2.1.2 There shall be a designated area with appropriate location and adequate space and design to minimize the risk of airborne microbial contamination in outpatient units where collection is performed.
-

- C2.1.3 There shall be a process to control storage areas to prevent mix-ups, contamination, and cross-contamination of all cellular therapy products prior to release or distribution.
- C2.1.4 There shall be suitable space for confidential donor examination and evaluation.
-
- C2.2 The Apheresis Collection Facility shall provide adequate lighting, ventilation, and access to sinks to prevent the introduction, transmission, or spread of communicable disease.
-
- C2.3 Apheresis Collection Facility parameters and environmental conditions shall be controlled to protect the safety and comfort of patients, donors, and personnel.
-
- C2.4 Critical Apheresis Collection Facility parameters that may affect cellular therapy product viability, integrity, contamination, sterility, or cross-contamination during collection, including temperature and humidity at a minimum, shall be assessed for risk to the cellular therapy product.
- C2.4.1 Critical facility parameters identified to be a risk to the cellular therapy product shall be controlled, monitored, and recorded.
-
- C2.5 When using collection methods that may result in contamination or cross-contamination of cellular therapy products, critical environmental conditions shall be controlled, monitored, and recorded, where appropriate, for air quality and surface contaminants.
-
- C2.6 The Apheresis Collection Facility shall document facility cleaning and sanitation and maintain order sufficient to achieve adequate conditions for operations.
-
- C2.7 There shall be adequate equipment and materials for the procedures performed.
-
- C2.8 There shall be access to an intensive care unit and/or emergency services.
-
- C2.9 The Apheresis Collection Facility shall be operated in a manner designed to minimize risks to the health and safety of employees, patients, donors, visitors, and volunteers.
-

- C2.10 The Apheresis Collection Facility shall have a written safety manual that includes instructions for action in case of exposure to communicable disease and to chemical, biological, or radiological hazards.

C3: PERSONNEL

C3.1 APHERESIS COLLECTION FACILITY DIRECTOR

- C3.1.1 There shall be an Apheresis Collection Facility Director with a medical degree or degree in a relevant science, qualified by postgraduate training or experience for the scope of activities carried out in the Apheresis Collection Facility. The Apheresis Collection Facility Director may also serve as the Apheresis Collection Facility Medical Director, if appropriately credentialed.
- C3.1.2 The Apheresis Collection Facility Director shall be responsible for all technical procedures, performance of the collection procedure, supervision of staff, administrative operations, and the Quality Management Program, including compliance with these Standards and other applicable laws and regulations.
- C3.1.3 The Apheresis Collection Facility Director shall have at least one year experience in cellular therapy product collection procedures.
- C3.1.4 The Apheresis Collection Facility Director shall have performed or supervised a minimum of five (5) cellular therapy product apheresis collection procedures in the twelve (12) months preceding accreditation and a minimum average of five (5) cellular therapy product apheresis collection procedures per year within the accreditation cycle.
- C3.1.5 The Apheresis Collection Facility Director shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
- C3.1.5.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation and apheresis.

C3.2 APHERESIS COLLECTION FACILITY MEDICAL DIRECTOR

- C3.2.1 There shall be an Apheresis Collection Facility Medical Director who is a licensed or certified physician with postgraduate training in cell collection and/or transplantation.
- C3.2.2 The Apheresis Collection Facility Medical Director or designee shall be responsible for the medical care of donors undergoing apheresis, including the pre-collection evaluation of the donor at the time of donation and care of any complications resulting from the collection procedure.

- C3.2.3 The Apheresis Collection Facility Medical Director shall have at least one year experience in performing and/or supervising cellular therapy product collection procedures.
- C3.2.4 The Apheresis Collection Facility Medical Director shall have performed or supervised a minimum of five (5) cellular therapy product apheresis collection procedures in the twelve (12) months preceding accreditation and a minimum average of five (5) cellular therapy product apheresis collection procedures per year within the accreditation cycle.
- C3.2.5 The Apheresis Collection Facility Medical Director shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
- C3.2.5.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation and apheresis.

C3.3 QUALITY MANAGER

- C3.3.1 There shall be an Apheresis Collection Facility Quality Manager to establish and maintain systems to review, modify, and approve all policies and procedures intended to monitor compliance with these Standards and/or the performance of the Apheresis Collection Facility.
- C3.3.2 The Quality Manager should have a reporting structure independent of cellular therapy product manufacturing.
- C3.3.3 The Apheresis Collection Facility Quality Manager shall participate in ten (10) hours of educational activities related to cellular therapy, cell collection, and/or quality management annually at a minimum.
- C3.3.3.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation.

C3.4 STAFF

- C3.4.1 The number of trained collection personnel shall be adequate for the number of procedures performed and shall include a minimum of one designated trained individual with an identified trained backup to maintain sufficient coverage.
- C3.4.2 For Apheresis Collection Facilities collecting cellular therapy products from pediatric donors, physicians and collection staff shall have documented training and experience in performing these procedures.

C4: QUALITY MANAGEMENT

C4.1 The Apheresis Collection Facility Director or designee shall have authority over and responsibility for ensuring that the Quality Management Program is effectively established and maintained.

C4.1.1 The Apheresis Collection Facility Director or designee shall annually review the effectiveness of the Quality Management Program. Documentation of the review findings shall be provided to the Clinical Program Director.

C4.2 The Apheresis Collection Facility shall establish and maintain a written Quality Management Plan.

C4.2.1 The Apheresis Collection Facility Director or designee shall be responsible for the Quality Management Plan as it pertains to the Apheresis Collection Facility.

C4.2.2 The Apheresis Collection Facility Director or designee shall review and report to staff quality management activities, at a minimum, quarterly.

C4.2.3 The Apheresis Collection Facility Director or designee shall not have oversight of his/her own work if this person also performs other tasks in the Apheresis Collection Facility.

C4.3 The Quality Management Plan shall include, or summarize and reference, an organizational chart of key positions and functions within the Apheresis Collection Facility.

C4.3.1 The Quality Management Plan shall include a description of how these key positions interact to implement the quality management activities.

C4.4 The Quality Management Plan shall include, or summarize and reference, policies and Standard Operating Procedures addressing personnel requirements for each key position in the Apheresis Collection Facility. Personnel requirements shall include at a minimum:

C4.4.1 A current job description for all staff.

C4.4.2 A system to document the following for all staff:

C4.4.2.1 Initial qualifications.

C4.4.2.2 New employee orientation.

C4.4.2.3 Initial training and retraining when appropriate for all procedures performed.

C4.4.2.4 Competency for each critical function performed.

C4.4.2.5 Continued competency at least annually.

C4.4.2.6 Continuing education.

C4.5 The Quality Management Plan shall include, or summarize and reference, a comprehensive system for document control and management.

C4.5.1 There shall be policies and procedures for development, approval, implementation, review, revision, and archival of all critical documents.

C4.5.2 There shall be a current listing of all active critical documents that shall comply with the document control system requirements. Controlled documents shall include at a minimum:

C4.5.2.1 Policies and Standard Operating Procedures.

C4.5.2.2 Worksheets.

C4.5.2.3 Forms.

C4.5.2.4 Labels.

C4.5.3 The document control policy shall include:

C4.5.3.1 A standardized format for policies, procedures, worksheets, forms, and labels.

C4.5.3.2 Assignment of numeric or alphanumeric identifier and title to each document and document version regulated within the system.

C4.5.3.3 A procedure for document approval, including the approval date, signature of approving individual(s), and the effective date.

C4.5.3.4 A system to protect controlled documents from accidental or unauthorized modification.

C4.5.3.5 A system for document change control that includes a description of the change, the signature of the approving individual(s), approval date, effective date, and archival date.

C4.5.3.6 Archived policies and procedures, the inclusive dates of use, and their historical sequence shall be maintained for a minimum of ten (10) years from archival or according to governmental or institutional policy, whichever is longer.

C4.5.3.7 A system for the retraction of obsolete documents to prevent unintended use.

C4.5.3.8 A system for record creation, assembly, review, storage, archival, and retrieval.

-
- C4.6 The Quality Management Plan shall include, or summarize and reference, policies and procedures for establishment and maintenance of written agreements with third parties whose services impact the cellular therapy product or clinical care of the donor.
- C4.6.1 Agreements shall include the responsibility of the facility performing any step in collection, processing, or testing to comply with applicable laws and regulations and these Standards.
- C4.6.2 Agreements shall be dated and reviewed on a regular basis.
-
- C4.7 The Quality Management Plan shall include, or summarize and reference, policies and procedures for documentation and review of outcome analysis and cellular therapy product efficacy to verify that the procedures in use consistently provide a safe and effective product.
- C4.7.1 Criteria for cellular therapy product safety, product efficacy, and/or the clinical outcome shall be determined and shall be reviewed at regular time intervals.
- C4.7.2 Both individual cellular therapy product data and aggregate data for each type of cellular therapy product shall be evaluated.
- C4.7.3 For HPC products intended for hematopoietic reconstitution, time to engraftment following product administration measured by ANC and platelet count shall be analyzed.
-
- C4.8 The Quality Management Plan shall include, or summarize and reference, policies, procedures, and a schedule for conducting, reviewing, and reporting audits of the Apheresis Collection Facility's activities to verify compliance with elements of the Quality Management Program and operational policies and procedures.
- C4.8.1 Audits shall be conducted on a regular basis by an individual with sufficient expertise to identify problems, but who is not solely responsible for the process being audited.
- C4.8.2 The results of audits shall be used to recognize problems, detect trends, identify improvement opportunities, implement corrective and preventive actions when necessary, and follow up on the effectiveness of these actions in a timely manner.
- C4.8.3 Audits shall include the following annually at a minimum:
- C4.8.3.1 Documentation of proper donor eligibility determination prior to start of the collection procedure.
- C4.8.3.2 Documentation that external facilities performing critical contracted services have met the requirements of the written agreements.
-

- C4.9 The Quality Management Plan shall include, or summarize and reference, policies and procedures on the management of cellular therapy products with positive microbial culture results that address at a minimum:
- C4.9.1 Notification of the recipient's physician.
 - C4.9.2 Investigation of cause.
 - C4.9.3 Follow-up of the donor, if relevant.
-
- C4.10 The Quality Management Plan shall include, or summarize and reference, policies and procedures for errors, accidents, biological product deviations, serious adverse events, and complaints, including the following activities at a minimum:
- C4.10.1 Detection.
 - C4.10.2 Investigation.
 - C4.10.2.1 A thorough investigation shall be conducted by the Apheresis Collection Facility in collaboration with the Processing Facility and Clinical Program, as appropriate.
 - C4.10.2.2 Investigations shall identify the root cause and a plan for short- and long-term corrective actions as warranted.
 - C4.10.3 Documentation.
 - C4.10.3.1 Documentation shall include a description of the event, the involved individuals and/or cellular therapy products, when the event occurred, when and to whom the event was reported, and the immediate actions taken.
 - C4.10.3.2 All investigation reports shall be reviewed in a timely manner by the Apheresis Collection Facility Director, Medical Director, or designee and the Quality Manager.
 - C4.10.3.3 Cumulative files of errors, accidents, biological product deviations, serious adverse events, and complaints shall be maintained.
 - C4.10.3.4 Cumulative files shall include written investigation reports containing conclusions, follow-up, corrective actions, and a link to the record(s) of the involved cellular therapy products
 - C4.10.4 Reporting.
 - C4.10.4.1 When it is determined that a cellular therapy product was responsible for an adverse reaction, the reaction and results of the investigation shall be reported to the recipient's physician, other facilities participating in the manufacturing of the cellular therapy product, registries, and governmental agencies as required by applicable laws.

C4.10.4.2 Errors, accidents, biological product deviations, and complaints shall be reported to other facilities performing cellular therapy product functions on the affected cellular therapy product and to the appropriate regulatory and accrediting agencies, registries, grant agencies, and IRBs or Ethics Committees.

C4.10.5 Corrective and preventive action.

C4.10.5.1 Appropriate corrective action shall be implemented if indicated, including both short-term action to address the immediate problem and long-term action to prevent the problem from recurring.

C4.10.5.2 Follow-up audits of the effectiveness of corrective actions shall be performed in a timeframe as indicated in the investigative report.

C4.11 The Quality Management Plan shall include, or summarize and reference, policies and procedures for cellular therapy product tracking and tracing that allow tracking from the donor to the recipient or final disposition and tracing from the recipient or final disposition to the donor.

C4.12 The Quality Management Plan shall include, or summarize and reference, policies and procedures for actions to take in the event the Apheresis Collection Facility's operations are interrupted.

C4.13 The Quality Management Plan shall include, or summarize and reference, policies and procedures for qualification of critical reagents, supplies, equipment, and facilities.

C4.13.1 Qualification plans shall be reviewed and approved by the Apheresis Collection Facility Director or designee.

C4.14 The Quality Management Plan shall include, or summarize and reference, policies and procedures for validation and/or verification of critical procedures to achieve the expected end-points, including viability of cells and cellular therapy product characteristics.

C4.14.1 Critical procedures shall include at least the following: collection procedures, labeling, storage, and distribution.

C4.14.2 Each validation shall include:

C4.14.2.1 An approved validation plan, including conditions to be validated.

C4.14.2.2 Acceptance criteria.

C4.14.2.3 Data collection.

- C4.14.2.4 Evaluation of data.
- C4.14.2.5 Summary of results.
- C4.14.2.6 Review and approval of the validation plan, results, and conclusion by the Apheresis Collection Facility Director or designee and the Quality Manager or designee.
- C4.14.3 Changes to a process shall include evaluation of risk to confirm that they do not create an adverse impact anywhere in the operation and shall be validated or verified as appropriate.

C5: POLICIES AND PROCEDURES

- C5.1 The Apheresis Collection Facility shall establish and maintain policies and/or procedures addressing critical aspects of operations and management in addition to those required in C4. These documents shall include all elements required by these Standards and shall address at a minimum:
 - C5.1.1 Donor and recipient confidentiality.
 - C5.1.2 Donor consent.
 - C5.1.3 Donor screening, testing, eligibility determination, and management.
 - C5.1.4 Management of donors who require central venous access.
 - C5.1.5 Cellular therapy product collection.
 - C5.1.6 Administration of blood products.
 - C5.1.7 Prevention of mix-ups and cross-contamination.
 - C5.1.8 Labeling (including associated forms and samples).
 - C5.1.9 Cellular therapy product expiration dates.
 - C5.1.10 Cellular therapy product storage.
 - C5.1.11 Release and exceptional release.
 - C5.1.12 Transportation and shipping, including methods and conditions to be used for distribution to external facilities.
 - C5.1.13 Critical reagent and supply management.
 - C5.1.14 Equipment operation, maintenance, and monitoring including corrective actions in the event of failure.

- C5.1.15 Recalls of equipment, supplies, and reagents.
 - C5.1.16 Cleaning and sanitation procedures including identification of the individuals responsible for the activities.
 - C5.1.17 Hygiene and use of personal protective attire.
 - C5.1.18 Disposal of medical and biohazard waste.
 - C5.1.19 Emergency and disaster plan, including the Apheresis Collection Facility response.
-
- C5.2 The Apheresis Collection Facility shall maintain a detailed Standard Operating Procedures Manual that includes a listing of all current Standard Operating Procedures, including title, identifier, and version.
-
- C5.3 Standard Operating Procedures shall be sufficiently detailed and unambiguous to allow qualified staff to follow and complete the procedures successfully. Each individual procedure shall include:
- C5.3.1 A clearly written description of the objectives.
 - C5.3.2 A description of equipment and supplies used.
 - C5.3.3 Acceptable end-points and the range of expected results.
 - C5.3.4 A stepwise description of the procedure.
 - C5.3.5 Age-specific issues where relevant.
 - C5.3.6 Reference to other Standard Operating Procedures or policies required to perform the procedure.
 - C5.3.7 A reference section listing appropriate literature.
 - C5.3.8 Documented approval of each procedure by the Apheresis Collection Facility Director or Medical Director, as appropriate, prior to implementation and every two years thereafter.
 - C5.3.9 Documented approval of each procedural modification by the Apheresis Collection Facility Director or Medical Director, as appropriate, prior to implementation.
 - C5.3.10 Reference to a current version of orders, worksheets, reports, labels, and forms.
-
- C5.4 Standard Operating Procedures relevant to processes being performed shall be readily available to the facility staff.

C5.5 Staff training and, if appropriate, competency shall be documented before performing a new or revised procedure.

C5.6 All personnel shall follow the Standard Operating Procedures related to their positions.

C5.7 Variances shall be pre-approved by the Apheresis Collection Facility Director and/or Medical Director, and reviewed by the Quality Manager.

C6: ALLOGENEIC AND AUTOLOGOUS DONOR EVALUATION AND MANAGEMENT

C6.1 There shall be written criteria for allogeneic and autologous donor evaluation and management by trained medical personnel.

C6.2 ALLOGENEIC AND AUTOLOGOUS DONOR INFORMATION AND CONSENT FOR COLLECTION

C6.2.1 The collection procedure shall be explained in terms the donor can understand, and shall include the following information at a minimum:

C6.2.1.1 The risks and benefits of the procedure.

C6.2.1.2 Tests and procedures performed on the donor to protect the health of the donor and the recipient.

C6.2.1.3 The rights of the donor or legally authorized representative to review the results of such tests according to applicable laws and regulations.

C6.2.1.4 Protection of medical information and confidentiality.

C6.2.2 Interpretation and translation shall be performed by individuals qualified to provide these services in the clinical setting.

C6.2.3 Family members and legally authorized representatives should not serve as interpreters or translators.

C6.2.4 The donor shall have an opportunity to ask questions.

C6.2.5 The donor shall have the right to refuse to donate.

C6.2.5.1 The allogeneic donor shall be informed of the potential consequences to the recipient of such refusal.

- C6.2.6 Donor informed consent for the cellular therapy product collection shall be obtained and documented by a licensed health care professional familiar with the collection procedure.
- C6.2.6.1 Informed consent from the allogeneic donor shall be obtained by a licensed health care professional who is not the primary health care professional overseeing care of the recipient.
- C6.2.7 In the case of a donor who is a minor, informed consent shall be obtained from the donor's legally authorized representative in accordance with applicable laws and regulations and shall be documented.
- C6.2.8 The allogeneic donor shall give informed consent and authorization prior to release of the donor's health or other information to the recipient's physician and/or the recipient.
- C6.2.9 Documentation of consent shall be available to the Apheresis Collection Facility staff prior to the collection procedure.
-
- C6.3 ALLOGENEIC AND AUTOLOGOUS DONOR SUITABILITY FOR CELLULAR THERAPY PRODUCT COLLECTION
- C6.3.1 There shall be criteria and evaluation policies and procedures in place to protect the safety of donors during the process of cellular therapy product collection.
- C6.3.1.1 The Apheresis Collection Facility shall confirm that any abnormal findings are reported to the prospective donor with documentation in the donor record of recommendations made for follow-up care.
- C6.3.1.2 Allogeneic donor suitability shall be evaluated by a licensed health care professional who is not the primary health care professional overseeing care of the recipient.
- C6.3.1.3 Autologous donors shall be tested as required by applicable laws and regulations.
- C6.3.2 The risks of donation shall be evaluated and documented, including:
- C6.3.2.1 Possible need for central venous access.
- C6.3.2.2 Mobilization therapy for collection of HPC, Apheresis.
- C6.3.3 The donor should be evaluated for the risk of hemoglobinopathy prior to administration of the mobilization regimen.
- C6.3.4 A pregnancy test shall be performed for all female donors with childbearing potential within seven (7) days prior to starting the donor mobilization regimen and, as applicable, within seven (7) days prior to the initiation of the recipient's preparative regimen.

- C6.3.5 Laboratory testing of all donors shall be performed by a laboratory that is accredited, registered, or licensed in accordance with applicable laws and regulations.
- C6.3.6 The Clinical Program shall inform the Collection Facility and Processing Facility of donor test results or if any testing was not performed.
- C6.3.7 Collection from a donor who does not meet Clinical Program collection safety criteria shall require documentation of the rationale for his/her selection by the transplant physician. Collection staff shall document review of these donor safety issues.
- C6.3.8 There shall be written documentation of issues of donor health that pertain to the safety of the collection procedure available to the Apheresis Collection Facility staff. Collection staff shall document review of these issues prior to collection.
- C6.3.9 There shall be a policy for follow-up of donors that includes routine management and the management of collection-associated adverse events.

C6.4 ADDITIONAL REQUIREMENTS FOR ALLOGENEIC DONORS

- C6.4.1 A donor advocate shall be available to represent allogeneic donors who are minors or who are mentally incapacitated.
- C6.4.2 Allogeneic donor infectious disease testing shall be performed using donor screening tests approved or cleared by the governmental authority.
- C6.4.3 The Apheresis Collection Facility shall comply with B6.4.6 through B6.4.6.8 when primarily responsible for donor screening for transmissible disease.
- C6.4.4 The Apheresis Collection Facility shall comply with B6.4.7 through B6.4.11 when primarily responsible for infectious and non-infectious disease testing of HPC donors.
- C6.4.5 The Apheresis Collection Facility shall comply with B6.4.3, B6.4.4, and B6.4.12 through B6.4.12.4 when primarily responsible for testing for the selection of allogeneic donors.
- C6.4.6 The Apheresis Collection Facility shall confirm that allogeneic donor eligibility, as defined by applicable laws and regulations, is determined by a physician after history, exam, medical record review, and testing before the donor begins the mobilization regimen.
- C6.4.7 Records required for donor eligibility determination shall be in English or translated into English when crossing international borders.
- C6.4.8 Collection of a cellular therapy product from an ineligible allogeneic donor, or from an allogeneic donor for whom donor eligibility determination is incomplete, shall require documentation of urgent medical need that includes the rationale for the selection and documentation of the informed consent of the donor and the recipient.

- C6.4.9 Allogeneic donor eligibility shall be communicated in writing to the Processing Facility.

-
- C6.5 There shall be a policy covering the creation and retention of donor records including at a minimum:

- C6.5.1 Donor identification including at least name and date of birth.
 - C6.5.2 Age, gender, and medical history, and, for allogeneic donors, behavioral history.
 - C6.5.3 Consent to donate.
 - C6.5.4 Results of laboratory testing.
 - C6.5.5 Allogeneic donor eligibility determination, including the name of the responsible person who made the determination and the date of the determination.
-

C7: CODING AND LABELING OF CELLULAR THERAPY PRODUCTS

C7.1 ISBT 128 CODING AND LABELING

- C7.1.1 Cellular therapy products shall be identified according to the proper name of the product, including appropriate attributes, as defined in ISBT 128 Standard Terminology for Blood, Cellular Therapy, and Tissue Product Descriptions.
 - C7.1.2 If coding and labeling technologies have not yet been implemented, the Apheresis Collection Facility shall be actively implementing ISBT 128.
-

C7.2 LABELING OPERATIONS

- C7.2.1 Labeling operations shall be conducted in a manner adequate to prevent mislabeling or misidentification of cellular therapy products, product samples, and associated records.
 - C7.2.1.1 Stocks of unused labels representing different products shall be stored in a controlled manner to prevent errors.
 - C7.2.1.2 Obsolete labels shall be restricted from use.
 - C7.2.2 Pre-printed labels shall be held upon receipt from the manufacturer pending review and proofing against a copy or template approved by the Apheresis Collection Facility Director or designee to confirm accuracy regarding identity, content, and conformity.
-

- C7.2.3 Print-on-demand label systems shall be validated to confirm accuracy regarding identity, content, and conformity of labels to templates approved by the Apheresis Collection Facility Director or designee.
- C7.2.4 A system for label version control shall be employed.
 - C7.2.4.1 Representative obsolete labels shall be archived minimally for ten (10) years after the last cellular therapy product was distributed with inclusive dates of use or as defined by applicable laws and regulations, whichever is longer.
- C7.2.5 A system of checks in labeling procedures shall be used to prevent errors in transferring information to labels.
 - C7.2.5.1 Cellular therapy products that are subsequently re-packaged into new containers shall be labeled with new labels before they are detached from the original container.
 - C7.2.5.2 A controlled labeling procedure consistent with applicable law shall be defined and followed if container label information is transmitted electronically during a labeling process. This procedure shall include a verification step.
- C7.2.6 When the label has been affixed to the container, a sufficient area of the container shall remain uncovered to permit inspection of the contents.
- C7.2.7 The information entered on a container label shall be verified by one (1) qualified staff member using a validated process to verify the information or two (2) qualified staff members.
- C7.2.8 Labeling elements required by applicable laws and regulations shall be present.
- C7.2.9 All data fields on labels shall be completed.
- C7.2.10 All labeling shall be clear, legible, and completed using ink that is indelible to all relevant agents.
- C7.2.11 Labels affixed directly to a cellular therapy product bag shall be applied using appropriate materials as defined by the applicable regulatory authority.
- C7.2.12 The label shall be validated as reliable for storage under the conditions in use.

C7.3 PRODUCT IDENTIFICATION

- C7.3.1 Each cellular therapy product collection shall be assigned a unique numeric or alphanumeric identifier by which it will be possible to trace any cellular therapy product to its donor, its recipient or final disposition, and all records.
 - C7.3.1.1 The cellular therapy product, product samples, concurrent plasma, and concurrently collected samples shall be labeled with the same identifier.

- C7.3.1.2 If a single cellular therapy product is stored in more than one container, there shall be a system to identify each container.
- C7.3.1.3 If cellular therapy products from the same donor are pooled, the pool identifier shall allow tracing to the original products.
- C7.3.1.4 Supplementary identifiers shall not obscure the original identifier.
- C7.3.1.5 The facility associated with each identifier shall be noted on the label.

C7.4 LABEL CONTENT

- C7.4.1 At the end of the cellular therapy product collection, the cellular therapy product label on the primary product container and concurrent plasma container shall bear the information in the Cellular Therapy Product Labeling table in Appendix II.
- C7.4.2 Each label shall bear the appropriate biohazard and warning labels as found in the Circular of Information (COI) for the Use of Cellular Therapy Products, "Table 2. Biohazard and Warning Labels on Cellular Therapy Products Collected, Processed, and/or Administered in the United States."
- C7.4.3 Labeling at the end of collection shall occur before the cellular therapy product bag is disconnected from the donor.
- C7.4.4 Cellular therapy products collected in or designated for use in the U.S. shall be accompanied by the elements listed in the Accompanying Documents at Distribution table in Appendix IV at the time of distribution.
- C7.4.5 For cellular therapy products distributed before completion of donor eligibility determination, there shall be documentation that donor eligibility determination was completed during or after the use of the product.
- C7.4.6 Cellular therapy products distributed for nonclinical purposes shall be labeled with the statement, "For Nonclinical Use Only."

C8: PROCESS CONTROLS

- C8.1 Collection of cellular therapy products shall be performed according to written procedures in the Apheresis Collection Facility's Standard Operating Procedures Manual.
- C8.2 There shall be a process for inventory control that encompasses equipment, reagents, supplies, and labels.

- C8.2.1 There shall be a system to uniquely identify and track and trace all critical equipment, reagents, supplies, and labels used in the collection of cellular therapy products.
- C8.2.2 Each supply and reagent used to collect cellular therapy products shall be visually examined at receipt and prior to use for damage or evidence of contamination.
- C8.2.3 Supplies and reagents coming into contact with cellular therapy products during collection shall be sterile and of the appropriate grade for the intended use.
-
- C8.3 Equipment shall be inspected for cleanliness prior to each use and verified to be in compliance with the maintenance schedule daily prior to use. Equipment shall also be standardized and calibrated on a regularly scheduled basis and after a critical repair or move as described in Standard Operating Procedures and in accordance with the manufacturer's recommendations.
- C8.3.1 All equipment with a critical measuring function shall be calibrated against a traceable standard, if available. Where no traceable standard is available, the basis for calibration shall be described and documented.
- C8.3.2 When equipment is found to be out of calibration or specification, there shall be a defined process for action required for cellular therapy products collected since the last calibration.
-
- C8.4 Equipment shall conform to applicable laws and regulations.
-
- C8.5 Autologous and/or CMV-appropriate and irradiated blood components shall be available during the apheresis collection procedure for all donors.
-
- C8.6 Before cell collection is undertaken, there shall be a written order from a physician specifying, at a minimum, timing and goals of collection.
-
- C8.7 A complete blood count, including platelet count, shall be performed within 24 hours prior to each subsequent cellular therapy product collection by apheresis.
-
- C8.8 There shall be peripheral blood count criteria to proceed with collection.
-

- C8.9 There shall be written documentation of an assessment of donor suitability for the collection procedure performed by a qualified person immediately prior to each collection procedure.
-
- C8.10 If required, central venous catheters shall be placed by a licensed health care professional qualified to perform the procedure.
- C8.10.1 Adequacy of central line placement shall be verified by the Apheresis Collection Facility prior to initiating the collection procedure.
-
- C8.11 Administration of mobilization agents shall be under the supervision of a licensed health care professional experienced in their administration and management of complications in persons receiving these agents.
-
- C8.12 The Apheresis Collection Facility shall utilize a process for assessing the quality of cellular therapy products to confirm product safety, viability, and integrity and to document that products meet predetermined release specifications. Results of all such assessments shall become part of the permanent record of the product collected.
- C8.12.1 Methods for collection shall include a process for controlling and monitoring the collection of cellular therapy products to confirm products meet predetermined release specifications.
- C8.12.2 Methods for collection shall employ procedures validated to result in acceptable cell viability and recovery.
-
- C8.13 Collection methods shall employ aseptic technique so that cellular therapy products do not become contaminated during collection.
-
- C8.14 Collection methods for pediatric donors shall employ appropriate age and size adjustments to the procedures.
-
- C8.15 Cellular therapy products shall be packaged in a closed sterile transfer pack appropriate for blood products.
-
- C8.16 Records shall be made concurrently with each step of collection of each cellular therapy product in such a way that all steps may be accurately traced.
-

- C8.16.1 Records shall identify the person immediately responsible for each significant step, including dates and times, where appropriate.

C8.17 There shall be a policy addressing safe administration of ECP.

- C8.17.1 Before ECP is undertaken, there shall be a written therapy plan from a physician specifying the patient's diagnosis and GVHD grade, involved organs, indication, timing of the procedure, proposed regimen, and any other factors that may affect the safe administration of ECP.
- C8.17.2 The ECP procedure shall be performed according to written standard operating procedures of the facility performing the procedure appropriate for the clinical condition of the patient.
- C8.17.3 A final report of the details of ECP administered shall be documented in the patient's medical record.

C9: CELLULAR THERAPY PRODUCT STORAGE

- C9.1 Apheresis Collection Facilities shall control storage areas to prevent mix-ups, deterioration, contamination, cross-contamination, and improper release or distribution of products.

- C9.2 Apheresis Collection Facilities shall establish policies for the duration and conditions of short-term storage prior to distribution to a Processing Facility or Clinical Program.

C10: CELLULAR THERAPY PRODUCT TRANSPORTATION AND SHIPPING

- C10.1 Procedures for transportation and shipping of the cellular therapy product shall be designed to protect the integrity of the product and the health and safety of individuals in the immediate area.

- C10.2 The primary cellular therapy product container shall be placed in a secondary container that is sealed to prevent leakage.

- C10.3 The cellular therapy product shall be transported and/or shipped to the Processing Facility in a validated container at a temperature defined in a Standard Operating Procedure.

- C10.3.1 Cellular therapy products that are transported and/or shipped from the collection site to the Processing Facility shall be transported and/or shipped in an outer container made of material adequate to withstand leakage of contents, impact shocks, pressure changes, temperature changes, puncture, and other conditions incident to ordinary handling.
- C10.3.2 If the intended recipient has received high-dose therapy, the cellular therapy product shall be transported.

C10.4 The cellular therapy product shall be transported and/or shipped with required accompanying records as defined in the transportation and shipping procedure and in compliance with C7.4.4 and C7.4.5.

C10.5 There shall be a record of the date and time of cellular therapy product distribution.

C11: RECORDS

C11.1 GENERAL REQUIREMENTS

- C11.1.1 A records management system shall be established and maintained to facilitate the review of records.
- C11.1.1.1 The records management system shall facilitate tracking of the cellular therapy product from the donor to the recipient or final disposition and tracing from the recipient or final disposition to the donor.
- C11.1.1.2 For cellular therapy products that are to be distributed for use at another institution, the Apheresis Collection Facility shall inform the receiving institution of the tracking system and requirement for tracking the product in writing or electronic format at or before the time of product distribution.
- C11.1.2 Records shall be maintained in such a way as to preserve their integrity, preservation, and retrieval.
- C11.1.3 Records shall be accurate, legible, and indelible.
- C11.1.4 Safeguards to secure the confidentiality of all records and communications between the collection, processing, and clinical facilities, and their recipients and donors, shall be established and followed in compliance with applicable laws and regulations.
-

C11.2 Apheresis Collection Facility records related to quality control, personnel training and competency, facility maintenance, facility management, complaints, or other general facility issues shall be retained for a minimum of ten (10) years by the Collection Facility, or longer in accordance with applicable laws and regulations, or a defined program or institution policy.

C11.2.1 Employee records shall be maintained in a confidential manner, as required by applicable laws and regulations.

C11.3 Records to allow tracking and tracing of cellular therapy products shall be maintained for a minimum of ten (10) years after final distribution of the product, or as required by applicable laws and regulations. These records shall include product identity, unique numeric or alphanumeric identifier, and collection date and time; and donor and recipient identification as far as known.

C11.4 Patient and donor records including, but not limited to, consents and records of care shall be maintained in a confidential manner as required by applicable laws and regulations for a minimum of ten (10) years after the administration of the cellular therapy product, or, if not known, ten (10) years after the date of the distribution, disposition, or expiration of the product, whichever requires the longest maintenance period.

C11.5 Research records shall be maintained in a confidential manner as required by applicable laws and regulations for a minimum of ten (10) years after the administration, distribution, disposition, or expiration of the cellular therapy product, whichever is latest.

C11.6 ELECTRONIC RECORDS

C11.6.1 The Apheresis Collection Facility shall maintain a current listing of all critical electronic record systems. Critical electronic record systems shall include at a minimum systems under the control of the Apheresis Collection Facility that are used as a substitute for paper, to make decisions, to perform calculations, or to create or store information used in critical procedures.

C11.6.2 For all critical electronic record systems, there shall be policies, procedures, and system elements to maintain the accuracy, integrity, identity, and confidentiality of all records.

C11.6.3 There shall be a means by which access to electronic records is limited to authorized individuals.

C11.6.4 The critical electronic record system shall maintain unique identifiers.

C11.6.5 There shall be protection of the records to enable their accurate and ready retrieval throughout the period of record retention.

- C11.6.6 For all critical electronic record systems, there shall be an alternative system for all electronic records to allow for continuous operation in the event that critical electronic record systems are not available. The alternative system shall be validated and Apheresis Collection Facility staff shall be trained in its use.
- C11.6.7 For all critical electronic record systems, there shall be written procedures for record entry, verification, and revision.
- C11.6.7.1 A method shall be established or the system shall provide for review of data before final acceptance.
- C11.6.7.2 A method shall be established or the system shall provide for the unambiguous identification of the individual responsible for each record entry.
- C11.6.8 For all critical electronic record systems, there shall be the ability to generate true copies of the records in both human readable and electronic format suitable for inspection and review.
- C11.6.9 For all critical electronic record systems, there shall be validated procedures for and documentation of:
- C11.6.9.1 Training and continued competency of personnel in systems use.
- C11.6.9.2 Monitoring of data integrity.
- C11.6.9.3 Back-up of the electronic records system on a regular schedule.
- C11.6.9.4 System assignment of unique identifiers.

C11.7 RECORDS IN CASE OF DIVIDED RESPONSIBILITY

- C11.7.1 The Apheresis Collection Facility shall furnish to the facility of final disposition a copy of all records relating to the collection procedures performed in so far as they concern the safety, purity, or potency of the cellular therapy product involved.
- C11.7.2 If two (2) or more facilities participate in the collection, processing, or administration of the cellular therapy product, the records of each facility shall show plainly the extent of its responsibility.

C12: DIRECT DISTRIBUTION TO CLINICAL PROGRAM

- C12.1 Where cellular therapy products are distributed directly from the Apheresis Collection Facility to the Clinical Program for administration or for subsequent processing, the Standards related to labeling, documentation, distribution, transportation, and recordkeeping in Sections D7, D10, D11, D13, and the Appendices apply.

PROCESSING FACILITY STANDARDS**PART D**

- D1 General
- D2 Processing Facility
- D3 Personnel
- D4 Quality Management
- D5 Policies and Procedures
- D6 Equipment, Supplies, and Reagents
- D7 Coding and Labeling of Cellular Therapy Products
- D8 Process Controls
- D9 Cellular Therapy Product Storage
- D10 Cellular Therapy Product Transportation and Shipping
- D11 Distribution and Receipt
- D12 Disposal
- D13 Records

PART D: PROCESSING FACILITY STANDARDS**D1: GENERAL**

-
- D1.1 These Standards apply to all processing, storage, and distribution activities performed in the Processing Facility on cellular therapy products obtained from living donors.
-
- D1.2 The Processing Facility shall abide by all applicable laws and regulations.
- D1.2.1 The Processing Facility shall be licensed, registered, or accredited as required by the appropriate governmental authorities for the activities performed.
-
- D1.3 The Processing Facility shall have a Processing Facility Director, a Processing Facility Medical Director, a Quality Manager, and at least one designated staff member actively performing cellular therapy product processing. This team shall have been in place for at least twelve (12) months preceding initial accreditation.
-

D2: PROCESSING FACILITY

-
- D2.1 The Processing Facility shall be of adequate space, design, and location, for the intended procedures.
- D2.1.1 The Processing Facility shall provide adequate lighting, ventilation, and access to sinks to prevent the introduction, transmission, or spread of communicable disease.
- D2.1.2 Oxygen sensors shall be appropriately placed and utilized in areas where liquid nitrogen is present.
- D2.1.3 The Processing Facility shall be secure to prevent the entrance of unauthorized personnel.
- D2.1.4 The Processing Facility shall be divided into defined areas of adequate size to prevent improper labeling, mix-ups, contamination, or cross-contamination of cellular therapy products.
- D2.1.5 There shall be a process to control storage areas to prevent mix-ups, contamination, and cross-contamination of all cellular therapy products prior to release or distribution.
-

- D2.2 Processing Facility parameters and environmental conditions shall be controlled to protect the safety and comfort of personnel.
-
- D2.3 Critical facility parameters that may affect processing, storage, or distribution, including temperature and humidity at a minimum, shall be assessed for risk to the cellular therapy product.
- D2.3.1 Critical facility parameters identified to be a risk to the cellular therapy product shall be controlled, monitored, and recorded.
-
- D2.4 When using procedures that may result in contamination or cross-contamination of cellular therapy products or when performing more than minimal manipulation, critical environmental conditions shall be controlled, monitored, and recorded where appropriate for air quality and surface contaminants.
- D2.4.1 The Processing Facility shall qualify environmental control systems and validate cleaning and sanitation procedures appropriate for the environmental classification and degree of manipulation performed.
-
- D2.5 The Processing Facility shall document facility cleaning and sanitation and maintain order sufficient to achieve adequate conditions for operations.
-
- D2.6 There shall be adequate equipment and materials for the procedures performed.
-
- D2.7 The Processing Facility shall be operated in a manner designed to minimize risks to the health and safety of employees, patients, donors, visitors, and volunteers.
-
- D2.8 The Processing Facility shall have a written safety manual that includes instructions for action in case of exposure, as applicable, to liquid nitrogen; communicable disease; and to chemical, biological, or radiological hazards.
-
- D2.9 All waste generated by the Processing Facility activities shall be disposed of in a manner that minimizes any hazard to facility personnel and to the environment in accordance with applicable laws and regulations.
-
- D2.10 Gloves and protective clothing shall be worn while handling biological specimens. Such protective clothing shall not be worn outside the work area.
-

D3: PERSONNEL

D3.1 PROCESSING FACILITY DIRECTOR

- D3.1.1 There shall be a Processing Facility Director with a medical degree, doctoral degree, or equivalent degree in a relevant science, qualified by a minimum of two (2) years training and experience for the scope of activities carried out in the Processing Facility.
 - D3.1.2 The Processing Facility Director shall be responsible for all procedures, administrative operations, and the Quality Management Program of the Processing Facility, including compliance with these Standards and other applicable laws and regulations.
 - D3.1.3 The Processing Facility Director shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
 - D3.1.3.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation and processing.
-

D3.2 PROCESSING FACILITY MEDICAL DIRECTOR

- D3.2.1 There shall be a Processing Facility Medical Director who is a licensed or certified physician with a minimum of two (2) years postgraduate training and practical and relevant experience for the scope of activities carried out in the preparation and clinical use of cellular therapy products.
 - D3.2.2 The Processing Facility Medical Director or designee shall be directly responsible for all medical aspects related to the Processing Facility.
 - D3.2.3 The Processing Facility Medical Director shall participate in ten (10) hours of educational activities related to cellular therapy annually at a minimum.
 - D3.2.3.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation and processing.
-

D3.3 QUALITY MANAGER

- D3.3.1 There shall be a Processing Facility Quality Manager to establish and maintain systems to review, modify, and approve all policies and procedures intended to monitor compliance with these Standards and/or the performance of the Processing Facility.

- D3.3.2 The Processing Facility Quality Manager should have a reporting structure independent of cellular therapy product manufacturing.
- D3.3.3 The Processing Facility Quality Manager shall participate in ten (10) hours of educational activities related to cellular therapy processing and/or quality management annually at a minimum.
- D3.3.3.1 Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation.

D3.4 STAFF

- D3.4.1 The number of trained processing personnel shall be adequate for the number of procedures performed and shall include a minimum of one designated trained individual with an identified trained backup to maintain sufficient coverage.

D4: QUALITY MANAGEMENT

- D4.1 The Processing Facility Director or designee shall have authority over and responsibility for ensuring that the Quality Management Program is effectively established and maintained.
- D4.1.1 The Processing Facility Director or designee shall annually review the effectiveness of the Quality Management Program. Documentation of the review findings shall be provided to the Clinical Program Director.
- D4.2 The Processing Facility shall establish and maintain a written Quality Management Plan.
- D4.2.1 The Processing Facility Director or designee shall be responsible for the Quality Management Plan as it pertains to the Processing Facility.
- D4.2.2 The Processing Facility Director or designee shall review and report to staff quality management activities, at a minimum, quarterly.
- D4.2.3 The Processing Facility Director or designee shall not have oversight of his/her own work if this person also performs other tasks in the Processing Facility.
- D4.3 The Quality Management Plan shall include, or summarize and reference, an organizational chart of key positions and functions within the Processing Facility.
- D4.3.1 The Quality Management Plan shall include a description of how these key positions interact to implement the quality management activities.

-
- D4.4 The Quality Management Plan shall include, or summarize and reference, policies and Standard Operating Procedures addressing personnel requirements for each key position in the Processing Facility. Personnel requirements shall include at a minimum:
- D4.4.1 A current job description for all staff.
 - D4.4.2 A system to document the following for all staff:
 - D4.4.2.1 Initial qualifications.
 - D4.4.2.2 New employee orientation.
 - D4.4.2.3 Initial training and retraining when appropriate for all procedures performed.
 - D4.4.2.4 Competency for each critical function performed.
 - D4.4.2.5 Continued competency at least annually.
 - D4.4.2.6 Continuing education.
-
- D4.5 The Quality Management Plan shall include, or summarize and reference, a comprehensive system for document control and management.
- D4.5.1 There shall be policies and procedures for development, approval, implementation, review, revision, and archival of all critical documents.
 - D4.5.2 There shall be a current listing of all active critical documents that shall comply with the document control system requirements. Controlled documents shall include at a minimum:
 - D4.5.2.1 Policies and Standard Operating Procedures.
 - D4.5.2.2 Worksheets.
 - D4.5.2.3 Forms.
 - D4.5.2.4 Labels.
 - D4.5.3 The document control policy shall include:
 - D4.5.3.1 A standardized format for policies, procedures, worksheets, forms, and labels.
 - D4.5.3.2 Assignment of a numeric or alphanumeric identifier and title to each document and document version regulated within the system.
 - D4.5.3.3 A procedure for document approval, including the approval date, signature of approving individual(s), and the effective date.
-

- D4.5.3.4 A system to protect controlled documents from accidental or unauthorized modification.
- D4.5.3.5 A system for document change control that includes a description of the change, the signature of approving individual(s), approval date(s), effective date, and archival date.
- D4.5.3.6 Archived policies and procedures, the inclusive dates of use, and their historical sequence shall be maintained for a minimum of ten (10) years from archival or according to governmental or institutional policy, whichever is longer.
- D4.5.3.7 A system for the retraction of obsolete documents to prevent unintended use.
- D4.5.3.8 A system for record creation, assembly, review, storage, archival, and retrieval.

D4.6 The Quality Management Plan shall include, or summarize and reference, policies and procedures for establishment and maintenance of written agreements with third parties whose services impact the cellular therapy product.

D4.6.1 Agreements shall include the responsibility of the facility performing any step in processing, testing, or storage to comply with applicable laws and regulations and these Standards.

D4.6.2 Agreements shall be dated and reviewed on a regular basis.

D4.7 The Quality Management Plan shall include, or summarize and reference, policies and procedures for review of outcome analysis and cellular therapy product efficacy to verify that the procedures in use consistently provide a safe and effective product.

D4.7.1 Criteria for cellular therapy product safety, product efficacy, and/or the clinical outcome shall be determined and shall be reviewed at regular time intervals.

D4.7.2 Both individual cellular therapy product data and aggregate data for each type of cellular therapy product shall be evaluated.

D4.7.3 For HPC products intended for hematopoietic reconstitution, time to engraftment following cellular therapy product administration measured by ANC and platelet count shall be analyzed.

D4.8 The Quality Management Plan shall include, or summarize and reference, policies, procedures, and a schedule for conducting, reviewing, and reporting audits of the Processing Facility's activities to verify compliance with elements of the Quality Management Program and operational policies and procedures.

- D4.8.1 Audits shall be conducted on a regular basis by an individual with sufficient expertise to identify problems, but who is not solely responsible for the process being audited.
 - D4.8.2 The results of audits shall be used to recognize problems, detect trends, identify improvement opportunities, implement corrective and preventive actions when necessary, and follow-up on the effectiveness of these actions in a timely manner.
 - D4.8.3 Documentation that external facilities performing critical contracted services have met the requirements of the written agreements shall be audited annually.
-
- D4.9 The Quality Management Plan shall include, or summarize and reference, policies and procedures on the management of cellular therapy products with positive microbial culture results that address at a minimum:
 - D4.9.1 Documentation and product labeling.
 - D4.9.2 Product quarantine.
 - D4.9.3 Criteria for product release.
 - D4.9.4 Identification of individuals authorized to approve release, including the Processing Facility Medical Director at a minimum.
 - D4.9.5 Investigation of cause.
 - D4.9.6 Notification of the recipient's physician, collection facility, and/or any other facility in receipt of the cellular therapy product.
 - D4.9.7 Reporting to regulatory agencies if appropriate.
-
- D4.10 The Quality Management Plan shall include, or summarize and reference, policies and procedures for errors, accidents, biological product deviations, serious adverse events, and complaints, including the following activities at a minimum:
 - D4.10.1 Detection.
 - D4.10.2 Investigation.
 - D4.10.2.1 A thorough investigation shall be conducted by the Processing Facility in collaboration with the Collection Facility and Clinical Program, as appropriate.
 - D4.10.2.2 Investigations shall identify the root cause and a plan for short- and long-term corrective actions as warranted.
 - D4.10.3 Documentation.

- D4.10.3.1 Documentation shall include a description of the event, the involved individuals and/or cellular therapy products, when the event occurred, when and to whom the event was reported, and the immediate actions taken.
- D4.10.3.2 All investigation reports shall be reviewed in a timely manner by the Processing Facility Director, Medical Director, or designee and the Quality Manager.
- D4.10.3.3 Cumulative files of errors, accidents, biological product deviations, serious adverse events, and complaints shall be maintained.
- D4.10.3.4 Cumulative files shall include written investigation reports containing conclusions, follow-up, corrective actions, and a link to the record(s) of the involved cellular therapy products.

D4.10.4 Reporting.

- D4.10.4.1 When it is determined that a cellular therapy product was responsible for a serious adverse reaction, the reaction report and results of the investigation shall be made available to the recipient's physician, other facilities participating in the manufacturing of the cellular therapy product, registries, and governmental agencies as required by applicable laws.
- D4.10.4.2 Errors, accidents, biological product deviations, and complaints shall be reported to other facilities performing cellular therapy product functions on the affected cellular therapy product and to the appropriate regulatory and accrediting agencies, registries, grant agencies, and IRBs or Ethics Committees.

D4.10.5 Corrective and preventive action.

- D4.10.5.1 Appropriate corrective action shall be implemented if indicated, including both short-term action to address the immediate problem and long-term action to prevent the problem from recurring.
- D4.10.5.2 Follow-up audits of the effectiveness of corrective actions shall be performed in a timeframe as indicated in the investigative report.

D4.11 The Quality Management Plan shall include, or summarize and reference, policies and procedures for cellular therapy product tracking and tracing that allow tracking from the donor to the recipient or final disposition and tracing from the recipient or final disposition to the donor.

D4.12 The Quality Management Plan shall include, or summarize and reference, policies and procedures for actions to take in the event the Processing Facility's operations are interrupted.

- D4.13 The Quality Management Plan shall include, or summarize and reference, policies and procedures for qualification of critical supplies, manufacturers, vendors, reagents, equipment, and facilities.
- D4.13.1 Qualification plans shall be reviewed and approved by the Processing Facility Director or designee.
 - D4.13.2 Reagents that are not the appropriate grade shall undergo qualification for the intended use.
-
- D4.14 The Quality Management Plan shall include, or summarize and reference, policies and procedures for validation and/or verification of critical procedures to achieve the expected end-points, including viability of cells and cellular therapy product characteristics.
- D4.14.1 Critical procedures to be validated or verified shall include at least the following: processing techniques, cryopreservation procedures, labeling, storage, and distribution.
 - D4.14.2 Each validation shall include:
 - D4.14.2.1 An approved validation plan, including conditions to be validated.
 - D4.14.2.2 Acceptance criteria.
 - D4.14.2.3 Data collection.
 - D4.14.2.4 Evaluation of data.
 - D4.14.2.5 Summary of results.
 - D4.14.2.6 Review and approval of the validation plan, results, and conclusion by the Processing Facility Director or designee and the Quality Manager or designee.
 - D4.14.3 Changes to a process shall include evaluation of risk to confirm that they do not create an adverse impact anywhere in the operation and shall be validated or verified as appropriate.
-

D5: POLICIES AND PROCEDURES

- D5.1 The Processing Facility shall establish and maintain policies and/or procedures addressing critical aspects of operations and management in addition to those required in D4. These documents shall include all elements required by these Standards and shall address at a minimum:
- D5.1.1 Donor and recipient confidentiality.

D5.1.2	Cellular therapy product receipt.
D5.1.3	Processing and process control.
D5.1.4	Processing of ABO-incompatible cellular therapy products to include a description of the indication for and processing methods to be used for red cell and plasma depletion.
D5.1.5	Prevention of mix-ups and cross-contamination.
D5.1.6	Labeling (including associated forms and samples).
D5.1.7	Cryopreservation and thawing.
D5.1.8	Cellular therapy product expiration dates.
D5.1.9	Cellular therapy product storage to include alternative storage if the primary storage device fails.
D5.1.10	Release and exceptional release.
D5.1.11	Transportation and shipping, including methods and conditions within the Processing Facility and to and from external facilities.
D5.1.12	Cellular therapy product recall, to include a description of responsibilities and actions to be taken, and notification of appropriate regulatory agencies.
D5.1.13	Cellular therapy product disposal.
D5.1.14	Critical reagent and supply management.
D5.1.15	Equipment operation, maintenance, and monitoring including corrective actions in the event of failure.
D5.1.16	Recalls of equipment, supplies, and reagents.
D5.1.17	Cleaning and sanitation procedures including identification of the individuals responsible for the activities.
D5.1.18	Environmental control to include a description of the environmental monitoring plan.
D5.1.19	Hygiene and use of personal protective equipment.
D5.1.20	Disposal of medical and biohazard waste.
D5.1.21	Emergency and disaster plan, including the Processing Facility response.
D5.2	The Processing Facility shall maintain a detailed Standard Operating Procedures Manual that includes a listing of all current Standard Operating Procedures, including title, identifier, and version.

-
- D5.3 Standard Operating Procedures shall be sufficiently detailed and unambiguous to allow qualified staff to follow and complete the procedures successfully. Each individual procedure shall include:
- D5.3.1 A clearly written description of the objectives.
 - D5.3.2 A description of equipment and supplies used.
 - D5.3.3 Acceptable end-points and the range of expected results.
 - D5.3.4 A stepwise description of the procedure.
 - D5.3.5 Reference to other Standard Operating Procedures or policies required to perform the procedure.
 - D5.3.6 A reference section listing appropriate literature.
 - D5.3.7 Documented approval of each procedure by the Processing Facility Director or Medical Director, as appropriate, prior to implementation and every two years thereafter.
 - D5.3.8 Documented approval of each procedural modification by the Processing Facility Director or Medical Director, as appropriate, prior to implementation.
 - D5.3.9 Reference to a current version of orders, worksheets, reports, labels, and forms.
-
- D5.4 Standard Operating Procedures relevant to processes being performed shall be readily available to the facility staff.
-
- D5.5 Staff training and, if appropriate, competency shall be documented before performing a new or revised procedure.
-
- D5.6 All personnel shall follow the Standard Operating Procedures related to their positions.
-
- D5.7 Variances shall be pre-approved by the Processing Facility Director and/or Medical Director, and reviewed by the Quality Manager.
-

D6: EQUIPMENT, SUPPLIES, AND REAGENTS

-
- D6.1 Equipment, supplies, and reagents used to process cellular therapy products shall be used in a manner that maintains product function and integrity and prevents product mix-ups, contamination, and cross-contamination.
-
- D6.2 Supplies and reagents used in processing, testing, cryopreservation, and storage shall be controlled by a materials management system that includes requirements for the following, at a minimum:
- D6.2.1 Visual examination of each supply and reagent used to manufacture cellular therapy products for damage or evidence of contamination upon receipt and acceptance into inventory.
 - D6.2.2 Records of receipt that shall include the supply or reagent type, quantity, manufacturer, lot number, date of receipt, acceptability, and expiration date.
 - D6.2.3 Storage of materials under the appropriate environmental conditions in a secure, sanitary, and orderly manner to prevent mix up or unintended use.
 - D6.2.4 Use of supplies and reagents coming into contact with cellular therapy products during processing, storage, and/or administration that are sterile and of the appropriate grade for the intended use.
 - D6.2.5 Cleaning and sterilizing of non-disposable supplies or instruments using a procedure verified to remove infectious agents and other contaminants.
 - D6.2.6 Use of supplies and reagents in a manner consistent with manufacturer instructions.
 - D6.2.7 Process to prevent the use of expired reagents and supplies.
-
- D6.3 There shall be a system to uniquely identify and track all critical equipment used in the processing of cellular therapy products. The system shall identify each cellular therapy product for which the equipment was used.
-
- D6.4 Equipment used in cellular therapy product processing, testing, cryopreservation, storage, and distribution shall be maintained in a clean and orderly manner and located to facilitate cleaning, sanitation, calibration, and maintenance according to established schedules.
-
- D6.5 The equipment shall be inspected for cleanliness prior to each use and verified to be in compliance with the maintenance schedule daily prior to use.
-

-
- D6.6 The equipment shall be standardized and calibrated on a regularly scheduled basis and after a critical repair or move as described in Standard Operating Procedures and in accordance with the manufacturer's recommendations.
- D6.6.1 All equipment with a critical measuring function shall be calibrated against a traceable standard, if available. Where no traceable standard is available, the basis for calibration shall be described and documented.
- D6.6.2 When equipment is found to be out of calibration or specification, there shall be a defined process for action required for cellular therapy products manufactured since the last calibration.
-
- D6.7 There shall be a procedure that addresses the actions to take in the event of equipment malfunction or failure.
-
- D6.8 Equipment shall conform to applicable laws and regulations.
-
- D6.9 Lot numbers, expiration dates, and manufacturers of critical reagents and supplies and identification of key equipment used in each procedure shall be documented.
-
- D6.10 The Processing Facility shall use an inventory control system to document the availability and identity of critical reagents and supplies. This shall include at a minimum:
- D6.10.1 A system to uniquely identify and track all critical reagents and supplies used to manufacture cellular therapy products.
- D6.10.2 A system to identify each cellular therapy product for which each critical reagent or supply was used.
- D6.10.3 A system to maintain adequate stocks of reagents and supplies for the procedures to be performed.
-

D7: CODING AND LABELING OF CELLULAR THERAPY PRODUCTS

- D7.1 ISBT 128 CODING AND LABELING
- D7.1.1 Cellular therapy products shall be identified according to the proper name of the product, including appropriate attributes, as defined in ISBT 128 Standard Terminology for Blood, Cellular Therapy, and Tissue Product Descriptions.
-

- D7.1.2 If coding and labeling technologies have not yet been implemented, the Processing Facility shall be actively implementing ISBT 128.

D7.2 LABELING OPERATIONS

- D7.2.1 Labeling operations shall be conducted in a manner adequate to prevent mislabeling or misidentification of cellular therapy products, product samples, and associated records.
- D7.2.1.1 Stocks of unused labels representing different cellular therapy products shall be stored in a controlled manner to prevent errors.
- D7.2.1.2 Obsolete labels shall be restricted from use.
- D7.2.2 Pre-printed labels shall be held upon receipt from the manufacturer pending review and proofing against a copy or template approved by the Processing Facility Director or designee to confirm accuracy regarding identity, content, and conformity.
- D7.2.3 Print-on-demand label systems shall be validated to confirm accuracy regarding identity, content, and conformity of labels to templates approved by the Processing Facility Director or designee.
- D7.2.4 A system for label version control shall be employed.
- D7.2.4.1 Representative obsolete labels shall be archived minimally for ten (10) years after the last cellular therapy product was distributed with inclusive dates of use or as defined by applicable laws and regulations, whichever is longer.
- D7.2.5 A system of checks in labeling procedures shall be used to prevent errors in transferring information to labels.
- D7.2.5.1 Cellular therapy products that are subsequently re-packaged into new containers shall be labeled with new labels before they are detached from the original container.
- D7.2.5.2 A controlled labeling procedure consistent with applicable law shall be defined and followed if container label information is transmitted electronically during a labeling process. This procedure shall include a verification step.
- D7.2.6 When the label has been affixed to the container, a sufficient area of the container shall remain uncovered to permit inspection of the contents.
- D7.2.7 The information entered on a container label shall be verified by one (1) qualified staff member using a validated process to verify the information or two (2) qualified staff members prior to distribution of the cellular therapy product.
- D7.2.8 Labeling elements required by applicable laws and regulations shall be present.
- D7.2.9 All data fields on labels shall be completed.

- D7.2.10 All labeling shall be clear, legible, and completed using ink that is indelible to all relevant agents.
- D7.2.11 Labels affixed directly to a cellular therapy product bag shall be applied using appropriate materials as defined by the applicable regulatory authority.
- D7.2.12 The label shall be validated as reliable for storage under the conditions in use.

D7.3 PRODUCT IDENTIFICATION

- D7.3.1 Each cellular therapy product shall be assigned a unique numeric or alphanumeric identifier by which it will be possible to trace any cellular therapy product to its donor, its recipient or final disposition, and all records.
 - D7.3.1.1 The cellular therapy product, product samples, concurrent plasma, and concurrently collected samples shall be labeled with the same identifier.
 - D7.3.1.2 If a single cellular therapy product is stored in more than one container, there shall be a system to identify each container.
 - D7.3.1.3 If cellular therapy products from the same donor are pooled, the pool identifier shall allow tracing to the original products.
 - D7.3.1.4 Supplementary identifiers shall not obscure the original identifier.
 - D7.3.1.5 The facility associated with each identifier shall be noted on the label.
 - D7.3.1.6 If the original identifier is replaced, documentation shall link the new identifier to the original.

D7.4 LABEL CONTENT

- D7.4.1 At the completion of processing and at distribution for administration, the cellular therapy product label on the primary product container and concurrent plasma container shall bear the information in the Cellular Therapy Product Labeling table in Appendix II.
- D7.4.2 Each label shall bear the appropriate biohazard and warning labels as found in the Circular of Information for the Use of Cellular Therapy Products, "Table 2. Biohazard and Warning Labels on Cellular Therapy Products Collected, Processed, and/or Administered in the United States."
- D7.4.3 Any container bearing a partial label shall be accompanied by the information required by the Cellular Therapy Product Labeling table in Appendix II. Such information shall be attached securely to the cellular therapy product on a tie tag or enclosed in a sealed package to accompany the product.

- D7.4.4 The name and address of the facility that determines that the cellular therapy product meets release criteria and the name and address of the facility that makes the product available for distribution shall either appear on the product label or accompany the product at distribution.
- D7.4.5 Cellular therapy products collected in or designated for use in the U.S. shall have the elements in the Accompanying Documents at Distribution table in Appendix IV accompany the cellular therapy product when it leaves the Processing Facility.
- D7.4.6 For cellular therapy products distributed before completion of donor eligibility determination, there shall be documentation that donor eligibility determination was completed during or after distribution of the cellular therapy product and that the physician using the product was informed of the results of that determination.
- D7.4.7 Cellular therapy products distributed for nonclinical purposes shall be labeled with the statement, "For Nonclinical Use Only."

D8: PROCESS CONTROLS

- D8.1 There shall be a process for controlling and monitoring the manufacturing of cellular therapy products so that products meet predetermined release specifications.
 - D8.1.1 The Processing Facility Director shall define tests and procedures for measuring and assaying cellular therapy products to assure their safety, viability, and integrity and to document that products meet predetermined release specifications. Results of all such tests and procedures shall become part of the permanent record of the product processed.
 - D8.1.2 There shall be a documented system for the identification and handling of test samples so that they are accurately related to the corresponding cellular therapy product, donor, or recipient.
 - D8.1.2.1 There shall be a mechanism to identify the individual obtaining the sample, the sample source, the date, and the time, if appropriate.
 - D8.1.2.2 Samples obtained for testing shall be representative of the cellular therapy product to be evaluated.
 - D8.1.3 There shall be the establishment of appropriate and validated assays and test procedures for the evaluation of cellular therapy products.
 - D8.1.3.1 For all cellular therapy products, a total nucleated cell count and viability measurement shall be performed.
 - D8.1.3.2 For HPC products intended for restoration of hematopoiesis, an assay measuring viable CD34 shall be performed.

- D8.1.3.3 For cellular therapy products undergoing manipulation that alters the final cell population, a relevant and validated assay, where available, shall be employed for evaluation of the viable target cell population before and after the processing procedures.
- D8.1.4 For tests required by these Standards performed within the Processing Facility:
- D8.1.4.1 There shall be a process for monitoring the reliability, accuracy, precision, and performance of laboratory test procedures and instruments.
 - D8.1.4.2 New reagent lots shall be verified to provide comparable results to current lots or to give results in agreement with suitable reference material before or concurrently with being placed into service.
 - D8.1.4.3 Where available, controls shall be used each day of testing and shown to give results within the defined range established for that material.
 - D8.1.4.4 Function checks shall be performed for testing instruments prior to testing donor, recipient, or cellular therapy product samples.
 - D8.1.4.5 For tests performed within the Processing Facility, there shall be documentation of ongoing proficiency testing as designated by the Processing Facility Director. The results shall be reviewed by the Processing Facility Director or designee and outcomes reviewed with the staff.
- D8.1.5 Tests required by these Standards, not performed by the Processing Facility, shall be performed by a laboratory that is certified, licensed, or accredited by the appropriate laboratory regulatory agency.
- D8.1.6 Infectious disease testing required by these Standards shall be performed using screening tests approved or cleared by the governmental authority for cellular therapy product donors.
- D8.1.7 Cellular therapy products that do not meet allogeneic donor eligibility requirements, or for which allogeneic donor eligibility determination is not yet complete, shall be distributed only if there is documented urgent medical need for the product. Documentation shall include, at a minimum, the approval of the recipient's physician and the Processing Facility Medical Director or other designated physician.
- D8.1.8 Notification of the recipient's physician of nonconforming cellular therapy products and approval for their release shall be documented.
-
- D8.2 Before a cellular therapy product is processed, shipped, or otherwise prepared for administration, there shall be a written request from the recipient's physician specifying the cellular therapy product type, recipient and donor identifiers, the type of processing that is to be performed, and the anticipated date of processing.
-

- D8.3 For allogeneic cellular therapy products, information required by the Processing Facility prior to distribution of the product shall include:
- D8.3.1 A statement of donor eligibility.
 - D8.3.2 For ineligible donors, the reason for their ineligibility.
 - D8.3.3 For ineligible donors or donors for whom eligibility determination is incomplete, documentation of urgent medical need and physician approval for use.
-
- D8.4 Processing procedures shall be validated in the Processing Facility and documented to result in acceptable target cell viability and recovery.
- D8.4.1 Published validated processes shall be verified within the Processing Facility prior to implementation.
 - D8.4.2 The Processing Facility shall use validated methods for preparation of cellular therapy products for administration.
 - D8.4.3 Cord blood units that have not been red cell reduced prior to cryopreservation shall be washed prior to administration.
 - D8.4.4 Cord blood units that have been red cell reduced prior to cryopreservation should be diluted or washed prior to administration.
 - D8.4.5 If the Processing Facility lacks experience with the type of cellular therapy product requested for a recipient, personnel shall obtain the manufacturer's instructions and follow these instructions to the extent possible.
 - D8.4.5.1 The Processing Facility should verify the processing procedures utilizing practice units similar to the cellular therapy product intended for administration when feasible.
-
- D8.5 Critical control points and associated assays shall be identified and performed on each cellular therapy product as defined in Standard Operating Procedures.
-
- D8.6 Methods for processing shall employ aseptic technique and cellular therapy products shall be processed in a manner that minimizes the risk of cross-contamination.
- D8.6.1 Where processing of tissues and cells involves exposure to the environment, processing shall take place in an environment with specified air quality and cleanliness.
 - D8.6.2 The effectiveness of measures to avoid contamination and cross-contamination shall be verified and monitored.
-

- D8.7 The Processing Facility shall monitor and document microbial contamination of cellular therapy products after processing as specified in Standard Operating Procedures.
- D8.7.1 The results of microbial cultures shall be reviewed by the Processing Facility Director or designee in a timely manner.
- D8.7.2 The recipient's physician shall be notified in a timely manner of any positive microbial cultures.
-
- D8.8 Records shall be made concurrently with each step of the processing, testing, cryopreservation, storage, and administration or disposal/disposition/distribution of each cellular therapy product in such a way that all steps may be accurately traced.
- D8.8.1 Records shall identify the person immediately responsible for each significant step, including dates and times, where appropriate.
- D8.8.2 Records shall show the test results and the interpretation of each result, where appropriate.
-
- D8.9 The Processing Facility Director or designee shall review the processing record for each cellular therapy product prior to release or distribution.
-
- D8.10 There shall be documented notification to the recipient's physician and the Processing Facility Medical Director of clinically relevant processing end-points not met and remedial actions taken.
-
- D8.11 Processing using more-than-minimal manipulation shall only be performed with Institutional Review Board or Ethics Committee approval, with the written informed consent of the donor, if applicable, and the recipient of the cellular therapy product, and in compliance with applicable laws and regulations.
- D8.11.1 The Processing Facility shall adhere to good manufacturing practices (GMP) appropriate for the degree of cellular therapy product manipulation.
-
- D8.12 For allogeneic cellular therapy products containing red blood cells at the time of administration:
- D8.12.1 Results for ABO group and Rh type testing shall be available from two (2) independently collected samples. Discrepancies shall be resolved and documented prior to issue of the cellular therapy product.
- D8.12.2 Results for a red cell antibody screen on the recipient shall be available.

D8.13 There shall be a procedure to confirm the identity of cord blood units if verification typing cannot be performed on attached segments.

D8.14 One or more samples representing the cryopreserved cellular therapy product shall be stored.

D8.14.1 Sample(s) from cryopreserved cellular therapy products shall be stored under conditions that achieve a valid representation of the clinical product.

D8.14.2 Cryopreserved samples shall be retained according to institutional Standard Operating Procedures.

D9: CELLULAR THERAPY PRODUCT STORAGE

D9.1 Processing Facilities shall control storage areas to prevent mix-ups, deterioration, contamination, cross-contamination, and improper distribution of cellular therapy products.

D9.2 STORAGE DURATION

D9.2.1 Processing Facilities processing, storing, and/or releasing cellular therapy products for administration shall assign an expiration date and time for non-cryopreserved products and for products thawed after cryopreservation.

D9.2.2 There shall be a written stability program that evaluates the viability and potency of cryopreserved cellular therapy products, minimally annually.

D9.3 TEMPERATURE

D9.3.1 Storage temperatures shall be defined in Standard Operating Procedures.

D9.3.2 Noncryopreserved cellular therapy products shall be maintained within a specific temperature range to maintain viability and function, to inhibit infectious agents, and for a period of time not to exceed that specified in Standard Operating Procedures.

D9.3.3 Cryopreserved cellular therapy products shall be stored within a temperature range, as defined in Standard Operating Procedures, that is appropriate for the product and cryoprotectant solution used.

- D9.3.4 Prior to receipt of a cellular therapy product from an external facility, there shall be confirmation that the product can be appropriately stored.

D9.4 PRODUCT SAFETY

- D9.4.1 Materials that may adversely affect cellular therapy products shall not be stored in the same refrigerators or freezers as the cellular therapy products.
- D9.4.2 For cellular therapy products immersed in liquid nitrogen, procedures to minimize the risk of cross-contamination of products shall be employed.
- D9.4.3 Processes for storing cellular therapy products in quarantine shall be defined in Standard Operating Procedures.
- D9.4.3.1 Quarantined cellular therapy products shall be easily distinguishable and stored in a manner that minimizes the risks of cross-contamination and inappropriate distribution.
- D9.4.3.2 All cellular therapy products with positive infectious disease test results for relevant communicable disease agents and/or positive microbial cultures shall be quarantined.
- D9.4.3.3 Processing Facilities storing cellular therapy products shall quarantine each product until completion of the donor eligibility determination as required by applicable laws and regulations.

D9.5 STORAGE MONITORING

- D9.5.1 Refrigerators and freezers used for storage where cellular therapy products are not fully immersed in liquid nitrogen shall have a system to monitor the temperature continuously and to record the temperature at least every four (4) hours.
- D9.5.2 There shall be a mechanism to confirm that levels of liquid nitrogen in liquid nitrogen freezers are consistently maintained to assure that cellular therapy products remain within the specified temperature range.

D9.6 ALARM SYSTEMS

- D9.6.1 Storage devices for cellular therapy products or reagents for cellular therapy product processing shall have alarm systems that are continuously active.
- D9.6.2 Alarm systems shall have audible and visible signals or other effective notification methods.
- D9.6.3 Alarm systems shall be checked periodically for function.

- D9.6.4 If trained personnel are not always present in the immediate area of the storage device, a system shall be in place that alerts responsible personnel of alarm conditions on a 24-hour basis.
- D9.6.5 Alarms shall be set to activate at a temperature or level of liquid nitrogen that will allow time to salvage products.
- D9.6.6 Written instructions to be followed if the storage device fails shall be displayed in the immediate area of the storage device and at each remote alarm location.
- D9.6.6.1 Instructions shall include a procedure for notifying processing personnel.
- D9.6.7 Storage devices of appropriate temperature shall be available for cellular therapy product storage if the primary storage device fails.
-
- D9.7 The storage device shall be located in a secure area and accessible only to authorized personnel.
-
- D9.8 The Processing Facility shall use an inventory control system to identify the location of each cellular therapy product and associated samples. The inventory control system records shall include:
- D9.8.1 Cellular therapy product unique identifier.
- D9.8.2 Recipient name or unique identifier.
- D9.8.3 Storage device identifier.
- D9.8.4 Location within the storage device.
-

D10: CELLULAR THERAPY PRODUCT TRANSPORTATION AND SHIPPING

- D10.1 Procedures for transportation and shipping of cellular therapy products shall be designed to protect the integrity of the product and the health and safety of individuals in the immediate area.
-
- D10.2 The primary product container for non-frozen cellular therapy products shall be placed in a secondary container and sealed to prevent leakage.
-

- D10.3 Cellular therapy products that require a temperature-controlled environment and that are transported or shipped over an extended period of time shall be transported or shipped in a container validated to maintain the appropriate temperature range.
-
- D10.4 Conditions shall be established and maintained to preserve the integrity and safety of cellular therapy products during transport or shipping.
-
- D10.5 Cellular therapy products that are shipped to another facility or transported on public roads shall be packaged in an outer container.
- D10.5.1 The outer container shall conform to the applicable regulations regarding the mode of transportation or shipping.
- D10.5.2 The outer container shall be made of material adequate to withstand leakage of contents, shocks, pressure changes, and other conditions incident to ordinary handling during transport or shipping.
- D10.5.2.1 The temperature of the shipping container shall be continuously monitored during shipment of cellular therapy products.
- D10.5.2.2 The shipping facility shall maintain a record of the temperature over the period of travel.
- D10.5.3 The outer container shall be secured.
- D10.5.4 The outer container shall be labeled as defined in the Cellular Therapy Product Labels for Shipping and Transport on Public Roads table in Appendix III.
- D10.5.5 There shall be a document inside the outer container that includes all the information required on the outer container, in conformity with the Cellular Therapy Product Labels for Shipping and Transport on Public Roads table in Appendix III.
- D10.5.6 The outer container shall be labeled in accordance with applicable laws and regulations regarding the cryogenic material used and the transport or shipment of biological materials.
-
- D10.6 The transit time shall be within time limits determined by the distributing facility in consultation with the receiving facility to maintain cellular therapy product safety.
-
- D10.7 If the intended recipient has received high-dose therapy, the cellular therapy product shall be transported.
-

D10.8 There shall be plans for alternative means of transport or shipping in an emergency.

D10.9 The cellular therapy products should not be passed through X-Ray irradiation devices designed to detect metal objects. If inspection is necessary, the contents of the container should be inspected manually.

D11: DISTRIBUTION AND RECEIPT

D11.1 DISTRIBUTION CRITERIA

D11.1.1 The processing, collection, and transport or shipping records for each cellular therapy product shall be reviewed by the Processing Facility Director or designee for compliance with Standard Operating Procedures and applicable laws and regulations prior to product release or distribution.

D11.1.1.1 Records shall demonstrate traceability from the donor to the recipient and from the recipient to the donor.

D11.1.2 Each cellular therapy product shall meet pre-determined release criteria prior to distribution from the Processing Facility. The release criteria shall include donor eligibility determination for allogeneic products.

D11.1.2.1 The Processing Facility Director or designee shall give specific authorization for release when the cellular therapy product does not meet technical release criteria.

D11.1.2.2 The Processing Facility Medical Director or designee shall give specific authorization for release when the cellular therapy product does not meet clinically relevant release criteria.

D11.1.2.3 Documentation of agreement of the Processing Facility Medical Director or designee and the recipient's physician consent to use any non-conforming product shall be retained in the processing record if such release is allowed by policies, procedures, or package inserts of licensed products.

D11.1.3 Each cellular therapy product issued for administration shall be visually inspected by two (2) trained personnel immediately before release to verify the integrity of the product container and appropriate labeling.

D11.1.3.1 A cellular therapy product shall not be released when the container is compromised and/or recipient or donor information is not verified unless the Processing Facility Director or designee gives specific authorization for the product's release.

D11.1.4 For each type of cellular therapy product, the Processing Facility shall maintain and distribute or make a document available to clinical staff containing the following:

- D11.1.4.1 The use of the cellular therapy product, indications, contraindications, side effects and hazards, dosage, and administration recommendations.
- D11.1.4.2 Instructions for handling the cellular therapy product to minimize the risk of contamination or cross-contamination.
- D11.1.4.3 Appropriate warnings related to the prevention of the transmission or spread of communicable diseases.

D11.2 The cellular therapy product processing records shall contain a written record of product distribution including, at a minimum:

- D11.2.1 The distribution date and time.
- D11.2.2 Unique identifier of the intended recipient.
- D11.2.3 The proper product name and identifier.
- D11.2.4 Documentation of donor eligibility determination.
- D11.2.5 Identification of the facilities that requested and distributed the product.

D11.3 Records shall permit tracing of the cellular therapy product from one facility to another, and shall include:

- D11.3.1 Date and time cellular therapy product was distributed.
- D11.3.2 Date and time cellular therapy product was received.
- D11.3.3 Identity of the transporting or shipping facility.
- D11.3.4 Identity of the receiving facility.
- D11.3.5 Identity of personnel responsible for cellular therapy product transportation or shipping and of personnel responsible for receiving the product.
- D11.3.6 Identity of the courier.
- D11.3.7 Documentation of any delay or problems incurred during transportation or shipping.

D11.4 RECEIPT OF CELLULAR THERAPY PRODUCTS

- D11.4.1 Procedures shall be established and maintained for acceptance, rejection, and quarantine of cellular therapy products.
- D11.4.2 The receipt of each cellular therapy product shall include inspection to verify:

- D11.4.2.1 The integrity of the cellular therapy product container.
- D11.4.2.2 The appearance of the cellular therapy product for evidence of mishandling or microbial contamination.
- D11.4.2.3 Appropriate labeling.
- D11.4.3 If the primary container or temperature of the cellular therapy product has been compromised, the Processing Facility Director or designee shall give specific authorization to return the product to inventory.
- D11.4.4 There shall be procedures to verify that the cellular therapy product was appropriately transported or shipped.
 - D11.4.4.1 The receiving facility shall document the temperature of the outer container upon arrival.
 - D11.4.4.2 For cryopreserved cellular therapy products, receiving facility records shall include documentation of the outer container temperature during shipping.
- D11.4.5 The receiving facility shall review and verify product specifications provided by the manufacturer, if applicable.
- D11.4.6 There shall be procedures to maintain cellular therapy products in quarantine until they have been determined to meet criteria for release from quarantine.
- D11.4.7 The receiving facility shall have readily available access to a summary of documents used to determine allogeneic donor eligibility.
 - D11.4.7.1 For cellular therapy products received from an external facility, there shall be documented evidence of donor eligibility screening and testing in accordance with applicable laws and regulations.
- D11.4.8 When cellular therapy products are returned to the Processing Facility after distribution for administration, there shall be documentation in the Processing Facility records of the events requiring return, the temporary storage temperature when at the clinical facility, the results of inspection upon return, and subsequent action taken to protect product safety and viability.
 - D11.4.8.1 The Processing Facility Director or designee shall consult with the recipient's physician regarding reissue or disposal of the returned product.

D12: DISPOSAL

- D12.1 Disposal of cellular therapy products shall include the following requirements:

- D12.1.1 A pre-collection written agreement between the storage facility and the designated recipient or the donor defining the length of storage and the circumstances for disposal of cellular therapy products.
- D12.1.2 The option to transfer the cellular therapy product to another facility if the designated recipient is still alive after the agreed upon storage interval.
- D12.1.3 Documentation of no further need for the cellular therapy product before any product is discarded.
 - D12.1.3.1 For HPC products, this shall include documentation of the designated recipient's death, if applicable.
- D12.1.4 Approval by the Processing Facility Medical Director or the recipient's physician for cellular therapy product discard or other disposition, and method of disposal.
- D12.1.5 A method of disposal and decontamination that meets applicable laws and regulations for disposal of biohazardous materials and/or medical waste.
- D12.1.6 Processing Facilities, in consultation with the Clinical Program, shall establish policies for the duration and conditions of storage and indications for disposal.
 - D12.1.6.1 Recipients, donors, and associated Clinical Programs should be informed about policies for directed cellular therapy products as part of the informed consent process and before the cellular therapy product collection.
- D12.1.7 If there is no pre-existing agreement describing conditions for cellular therapy product storage and/or discard or if the intended recipient is lost to follow-up, the storage facility shall make a documented effort to notify the donor, cellular therapy product manufacturer, or designated recipient's physician and facility about product disposition, including disposal or transfer.

-
- D12.2 The records for discarded or transferred cellular therapy products shall indicate the product was discarded or transferred, date of discard or transfer, disposition, and method of disposal or transfer.
-

D13: RECORDS

- D13.1 There shall be a records management system for quality and cellular therapy product record creation, assembly, review, storage, archival, and retrieval.
 - D13.1.1 The records management system shall facilitate the review of records pertaining to a particular cellular therapy product prior to distribution and for follow-up evaluation or investigation.

- D13.1.2 The records management system shall facilitate tracking of the cellular therapy product from the donor to the recipient or final disposition and tracing from the recipient or final disposition to the donor.
- D13.1.3 For cellular therapy products that are to be distributed for use at another institution, the Processing Facility shall inform the receiving institution of the tracking system and requirement for tracking the product in writing or electronic format at or before the time of product distribution.
- D13.1.4 Records shall be maintained in such a way as to secure their integrity, preservation, and retrieval.
- D13.1.5 Records shall be accurate, legible, and indelible.
- D13.1.6 Safeguards to secure the confidentiality of all records and communications between the collection, processing, and clinical facilities and their recipients and donors shall be established and followed in compliance with applicable laws and regulations.

D13.2 ELECTRONIC RECORDS

- D13.2.1 The Processing Facility shall maintain a current listing of all critical electronic record systems. Critical electronic record systems shall include at a minimum systems under the control of the Processing Facility that are used as a substitute for paper, to make decisions, to perform calculations, or to create or store information used in critical procedures.
- D13.2.2 For all critical electronic record systems, there shall be policies, procedures, and system elements to maintain the accuracy, integrity, identity, and confidentiality of all records.
 - D13.2.2.1 There shall be a means by which access to electronic records is limited to authorized individuals.
 - D13.2.2.2 The critical electronic record system shall maintain unique identifiers.
 - D13.2.2.3 There shall be protection of the records to enable their accurate and ready retrieval throughout the period of record retention.
- D13.2.3 For all critical electronic record systems, there shall be an alternative system for all electronic records to allow for continuous operation of the Processing Facility in the event that critical electronic record systems are not available. The alternative system shall be validated and Processing Facility staff shall be trained in its use.
- D13.2.4 For all critical electronic record systems, there shall be written procedures for record entry, verification, and revision.
 - D13.2.4.1 A method shall be established or the system shall provide for review of data before final acceptance.

- D13.2.4.2 A method shall be established or the system shall provide for the unambiguous identification of the individual responsible for each record entry.
- D13.2.5 For all critical electronic record systems, there shall be the ability to generate true copies of the records in both human readable and electronic format suitable for inspection and review.
- D13.2.6 For all critical electronic record systems, there shall be validated procedures for and documentation of:
 - D13.2.6.1 Systems development.
 - D13.2.6.2 Numerical designation of system versions, if applicable.
 - D13.2.6.3 Prospective validation of systems, including hardware, software, and databases.
 - D13.2.6.4 Installation of the system.
 - D13.2.6.5 Training and continued competency of personnel in systems use.
 - D13.2.6.6 Monitoring of data integrity.
 - D13.2.6.7 Back-up of the electronic records system on a regular schedule.
 - D13.2.6.8 System maintenance and operations.
 - D13.2.6.9 System assignment of unique identifiers.
- D13.2.7 All system modifications shall be authorized, documented, and validated prior to implementation.

D13.3 RECORDS TO BE MAINTAINED

- D13.3.1 Processing Facility records related to quality control, personnel training and competency, facility maintenance, facility management, complaints, or other general facility issues shall be retained for a minimum of ten (10) years by the Processing Facility, or longer in accordance with applicable laws or regulations, or with a defined program or institution policy.
 - D13.3.1.1 Facility maintenance records pertaining to facility cleaning and sanitation shall be retained for at least three (3) years or longer in accordance with applicable laws or regulations, or with defined program or institution policy. All other facility maintenance records shall be retained as in D13.3.1.

- D13.3.2 Records to allow tracing of cellular therapy products shall be maintained for a minimum of ten (10) years after final distribution of the product, or as required by applicable laws and regulations. These records shall include collection and processing facility identity, unique numeric or alphanumeric identifier, collection date and time, product identity, and donor and recipient information as found on the original container.
- D13.3.3 All records pertaining to the processing, testing, storage, or distribution of cellular therapy products shall be maintained for a minimum of ten (10) years after the date of administration, or if the date of administration is not known, then a minimum of ten (10) years after the date of the cellular therapy product's distribution, disposition, or expiration, or the creation of the cellular therapy product record, whichever is most recent, or according to applicable laws and regulations or institutional policy, whichever requires the longest maintenance period.

D13.4 RECORDS IN CASE OF DIVIDED RESPONSIBILITY

- D13.4.1 The Processing Facility shall maintain a listing of the names, addresses, and responsibilities of other facilities that perform manufacturing steps on a cellular therapy product.
- D13.4.2 The Processing Facility shall furnish to the facility of final disposition a copy of all records relating to the collection, processing, and storage procedures performed in so far as the records concern the safety, purity, or potency of the cellular therapy product involved.
- D13.4.3 If two (2) or more facilities participate in the collection, processing, or distribution of the cellular therapy product, the records of the Processing Facility shall show plainly the extent of its responsibility.

This page intentionally left blank.

APPENDIX I

MINIMUM NUMBER OF NEW PATIENTS FOR ACCREDITATION

Clinical Programs shall transplant at least the following number of new patients¹ before initial accreditation and annually thereafter:

Transplant Population	Clinical Site(s)	Type of Transplant	Twelve (12) Months Prior to Initial Accreditation	Average Per Year Within Accreditation Cycle
Adult OR Pediatric (only one of these two)	Single Clinical Site	Autologous only	5 autologous	5 autologous
		Allogeneic and Autologous	10 allogeneic recipients	10 allogeneic recipients
	Multiple Clinical Sites	Autologous only	5 autologous recipients at each site	5 autologous recipients at each site
		Allogeneic and Autologous	5 allogeneic recipients at each applicable site ² 5 autologous at each applicable site ²	5 allogeneic recipients at each applicable site ² 5 autologous at each applicable site ²
Combined Adult AND Pediatric	Single Clinical Site	Autologous only	5 adult autologous And 5 pediatric autologous recipients	5 adult autologous and 5 pediatric autologous recipients
		Allogeneic and Autologous	5 adult allogeneic recipients 5 pediatric allogeneic recipients	5 adult allogeneic recipients 5 pediatric allogeneic recipients
	Multiple Clinical Sites	Autologous only	5 adult autologous at each applicable site 5 pediatric autologous recipients at each applicable site	5 adult autologous recipients at each applicable site 5 pediatric autologous recipients at each applicable site
		Allogeneic and Autologous	5 adult allogeneic recipients at each applicable site 5 pediatric allogeneic recipients at each applicable site 5 adult autologous at each applicable site ² 5 pediatric autologous at each applicable site ²	5 adult allogeneic recipients at each site 5 pediatric allogeneic recipients at each site 5 adult autologous at each applicable site ² 5 pediatric autologous at each applicable site ²

¹The term “new allogeneic patient” or “new autologous patient” includes only a patient who received his/her first transplant of that type during the period of time in question.

²Programs performing allogeneic and autologous transplantation that have more than one clinical site may or may not perform both types of transplant at each site. The requirement for five autologous transplant recipients per site only applies to those sites that do not perform allogeneic transplant.

This page intentionally left blank.

APPENDIX II

CELLULAR THERAPY PRODUCT LABELING

Each label shall include at least the elements detailed in the following table¹:

Element ²	Partial label	Label at completion of collection	Label at completion of processing	Label at distribution for administration ⁴
Unique numeric or alphanumeric identifier ³	AF	AF	AF	AF
Proper name of product ⁵	AF	AF	AF	AF
Product attributes ⁵			AC	AC
Recipient name and/or identifier		AT	AT	AT
Identity and address of collection facility or donor registry		AT	AC	AC
Date, time collection ends, and (if applicable) time zone		AT	AC	AC
Approximate volume		AT	AT	AT
Name and quantity of anticoagulant and other additives		AC	AC	AC
Donor identifier and (if applicable) name		AT	AT	AT
Recommended storage temperature range		AT	AT	AT
Biohazard and/or Warning Labels (as applicable, see CM7.4, C7.4, D7.4).		AT	AT	AT
As applicable: - Statement "NOT EVALUATED FOR INFECTIOUS SUBSTANCES" - Statement "WARNING: Advise Patient of Communicable Disease Risks" - Statement "WARNING: Reactive Test Results for [name of disease agent or disease]"		AT AT AT	AT AT AT	AT AT AT
Identity and address of processing and distribution facility(ies)			AC	AC
Statement "Do Not Irradiate"			AT	AT
Expiration Date (if applicable)			AC	AC
Expiration Time (if applicable)			AC	AC
ABO and Rh of donor (if applicable)			AC	AC
RBC compatibility determination (if applicable)				AC
Statement indicating that leukoreduction filters shall not be used.				AT
Statement "FOR AUTOLOGOUS USE ONLY" (if applicable)		AT	AT	AT
Date of distribution				AC

AF=Affix, AT=Attach or Affix, AC=Accompany, Attach, or Affix

¹ Container and full package labeling requirements for licensed products or products under Investigational New Drug (IND) application shall follow applicable laws and regulations. In the U.S., see 21 CFR 312.6(a).

² Facilities registered with ICCBBA who have fully implemented ISBT 128 labeling shall follow the ISBT 128 Standard for the location of information on the label and/or the accompanying documentation.

³ Overlay labels for supplementary identifiers shall not obscure the original identifier.

⁴ Products thawed at the bedside do not require a new label unless repackaged into a new container.

⁵ Product proper names and attributes are listed in Chapter Three of the ISBT 128 Standard Terminology for Blood, Cellular Therapy, and Tissue Product Descriptions. Available at: www.iccbba.org > Subject Area > Cellular Therapy > Standard Terminology.

This page intentionally left blank.

APPENDIX III**CELLULAR THERAPY PRODUCT LABELS FOR SHIPPING AND TRANSPORT ON PUBLIC ROADS**

Each container for shipping and transport on public roads shall include a document on the inside of the container and a label on the exterior of the container with at least the elements detailed in the following table:

Element	Inner container document	Outer container label
Date of distribution	AC	AC
Time ¹ of distribution, if appropriate	AC	AC
Statement "Do Not X-Ray" and /or "Do Not Irradiate", if applicable	AC	AF
Statements "Human Cells for Administration" or equivalent and "Handle with Care"	AC	AF
Shipper handling instructions	AC	AF
Shipping facility name, street address, contact person, and phone number	AC	AF
Receiving facility name, street address, contact person, and phone number	AC	AF
Biohazard and/or Warning Labels (as applicable, see CM7.4.2, C7.4.2, D7.4.2).	AC	
If applicable: Statement "NOT EVALUATED FOR INFECTIOUS SUBSTANCES"	AC	
Statement "WARNING: Advise Patient of Communicable Disease Risks"	AC	
Statement "WARNING: Reactive Test Results for [name of disease agent or disease]"	AC	

AC= Accompany, AF=Affix

¹Time shall include the time zone when shipping or transport of the cellular therapy product involves crossing time zones.

This page intentionally left blank.

APPENDIX IV

ACCOMPANYING DOCUMENTS AT DISTRIBUTION

Products collected in or designated for use in the U.S. shall be accompanied upon leaving the Collection or Processing Facility with at least the elements detailed in the following table¹:

Documentation	Allogeneic Donors-Eligible	Allogeneic Donor-Ineligible ²	Allogeneic Donor-Incomplete ²
Statement that the donor has been determined to be either eligible or ineligible, based upon results of donor screening and testing	X	X	
Summary of records used to make the donor-eligibility determination ³	X	X	
Name and address of the establishment that made the donor-eligibility determination	X	X	
Listing and interpretation of the results of all communicable disease testing performed	X	X	X
Statement that the communicable disease testing was performed by a laboratory meeting regulatory requirements ⁴	X	If applicable	If applicable
Statement noting the reason(s) for the determination of ineligibility		X	
Statement that the donor-eligibility determination has not been completed			X
Statement that the product must not be transplanted or infused until completion of the donor-eligibility determination, except under condition of urgent medical need			X
Listing of any required screening or testing that has not yet been completed			X
Results of donor screening and testing that has been performed			X
Documentation that the physician using the cellular therapy product was notified of incomplete testing or screening			X
Instructions for product use to prevent the introduction, transmission, or spread of communicable diseases ¹	X	X	X
Instructions for reporting serious adverse reactions or events to the distributing facility ^{1,5}	X	X	X

¹For autologous cellular therapy products, instructions for product use to prevent the introduction, transmission, or spread of communicable diseases and for reporting serious adverse reactions or events to the distributing facility are always required for autologous products. Furthermore, a donor eligibility determination is not required by FDA. However, if any donor screening or testing is performed and risk factors or reactive test results are identified, accompanying documentation shall be provided.

²May only be distributed after release by the Processing Facility Medical Director due to urgent medical need. For ineligible cellular therapy products or incomplete donor eligibility determination, the product shall be shipped in quarantine. For products distributed prior to completion of donor eligibility, determination shall be completed and the physician shall be informed of the results.

³ Access (electronic or otherwise) to the source documents by the distributing facility and/or receiving facility is sufficient.

⁴This includes laboratories certified to perform such testing on human specimens under the Clinical Laboratory Improvement Amendments of 1988 or those laboratories that have met equivalent requirements as determined by the Centers for Medicare and Medicaid Services, or those that have met equivalent non-U.S. requirements.

⁵ Access to the Clinical Program SOPs and forms could suffice when the distributing and clinical facilities are within the same facility.

This page intentionally left blank.

APPENDIX V

CHANGES TO SIXTH EDITION STANDARDS

The table below outlines the changes made to the *FACT-JACIE International Standards for Cellular Therapy Product Collection, Processing, and Administration* with each version of the sixth edition of these Standards.¹

Version Number ²	Standard	Change
6.1	A3	<u>CAR (Chimeric antigen receptor)</u>
6.1	A3	<u>CNS (Central nervous system)</u>
6.1	A3	<u>CRS (Cytokine release syndrome)</u>
6.1	A3	<u>MSC (Mesenchymal stromal cell or mesenchymal stem cell)</u>
6.1	A3	<u>NC (Nucleated cell)</u>
6.1	A4	Cellular therapy product: Somatic cell-based product (e.g., mobilized HPC, mononuclear cells, cord blood cells, mesenchymal stromal cells, <u>T cells, natural killer cells</u>) that is procured from a donor and intended for processing and administration.
6.1	A4	<u>Chimeric antigen receptor: Artificial receptor that combines an antigen specificity domain coupled with an intracellular signaling domain typically expressed by an immune effector cell (e.g., T cell or natural killer cell).</u>
6.1	A4	Corrective action: Action taken to eliminate the <u>root</u> causes of an existing discrepancy or other undesirable situation to prevent recurrence.
6.1	A4	<u>Cytokine release syndrome: A non-antigen-specific toxicity that occurs as a result of high-level immune activation. For example, a reaction from the release of cytokines from cells targeted by an antibody or immune effector cells.</u>
6.1	A4	<u>Immune effector cell: A cell that has differentiated into a form capable of modulating or effecting a specific immune response.</u>
6.1	A4	Preventive action: Action taken to eliminate the <u>root</u> cause and prevent occurrence of a potential discrepancy or other undesirable situation.
6.1	A4	<u>Product identity: Unique title that identifies the cellular composition of the product in a way that can be directly tied back to a manufacturing entity or process (e.g., a protocol number, a commercial product title, or a site-defined unique identifier).</u>

Version Number ²	Standard	Change
6.1	A4	Quality assurance: The actions, planned and performed, to provide confidence that all systems and elements that influence the quality of the product or service are working as expected <u>or exceed expectations</u> individually and collectively.
6.1	B1.2.1	<u>If cellular therapy products are received directly by the Clinical Program from a third-party provider, the following responsibilities at a minimum shall be defined in a written agreement:</u>
6.1	B1.2.1.1	<u>Traceability and chain of custody of cellular therapy products.</u>
6.1	B1.2.1.2	<u>Cellular therapy product storage and distribution.</u>
6.1	B1.2.1.3	<u>Verification of cellular therapy product identity.</u>
6.1	B2.6	There shall be written guidelines for communication, patient monitoring, and prompt transfer of patients to an intensive care unit, <u>emergency department</u> , or equivalent when appropriate.
6.1	B2.8.1	<u>Pharmacies shall have access to medications adequate to treat expected complications of immune effector cell administration, including cytokine release syndrome.</u>
6.1	B3.3.3	Clinical Program Directors and attending physicians shall have received specific training and maintain competency in each of the following areas <u>as applicable to the Clinical Program's services:</u>
6.1	B3.3.3.12	Diagnosis and management of veno-occlusive disease of the liver <u>and other causes of hepatic dysfunction.</u>
6.1	B3.3.3.13	Management of thrombocytopenia and bleeding, <u>including recognition of disseminated intravascular coagulation.</u>
6.1	B3.3.3.17	<u>Graft versus host disease.</u>
6.1	B3.3.3.18	<u>Cytokine release syndrome.</u>
6.1	B3.3.3.19	<u>Tumor lysis syndrome.</u>
6.1	B3.3.3.20	<u>Macrophage activation syndrome.</u>
6.1	B3.3.3.21	<u>Cardiac dysfunction.</u>
6.1	B3.3.3.22	<u>Renal dysfunction.</u>
6.1	B3.3.3.23	<u>Respiratory distress.</u>
6.1	B3.3.3.24	<u>Neurologic toxicity.</u>
6.1	B3.3.3.25	<u>Anaphylaxis.</u>
6.1	B3.3.3.26	<u>Infectious and noninfectious processes.</u>
6.1	B3.3.5.7	<u>Cellular therapy product administration.</u>

Version Number ²	Standard	Change
6.1	B3.7.3.4	Care interventions to manage transplant <u>cellular therapy</u> complications, including, but not limited to, <u>cytokine release syndrome, tumor lysis syndrome, cardiac dysfunction, respiratory distress, neurologic toxicity, renal and hepatic failure, disseminated intravascular coagulation, anaphylaxis, neutropenic fever, infectious and noninfectious processes, mucositis, nausea and vomiting, and pain management.</u>
6.1	B3.7.4.6	<u>Detection and management of immune effector cellular therapy complications including, but not limited to, those listed in B3.7.3.4.</u>
6.1	B3.8.2.1	An overview of hematology/oncology patient care, including the cellular therapy process, <u>cytokine release syndrome, and neurological toxicities.</u>
6.1	B3.8.3	Pharmacists should <u>shall</u> be involved in the development and implementation of guidelines or SOPs related to the pharmaceutical management of transplant-cellular therapy recipients.
6.1	B3.8.4.1	Continuing education shall include, but is not limited to, activities related to the field of HPC transplantation <u>and cytokine release syndrome and neurological toxicities resulting from cellular therapies.</u>
6.1	B3.10.2	<u>The Clinical Program Quality Manager should have a reporting structure independent of cellular therapy product manufacturing.</u>
6.1	B4.7.3.2	<u>For immune effector cells, an endpoint of clinical function as approved by the Clinical Program Director.</u>
6.1	B4.7.3.3	Overall and treatment-related morbidity and mortality at <u>thirty (30) days, one hundred (100) days, and one (1) year after transplantation cellular therapy product administration.</u>
6.1	B4.8.3.1	<u>Periodic audit of the accuracy of clinical data.</u>
6.1	B4.8.3.2	<u>Annual audit of safety endpoints and immune effector cellular therapy toxicity management.</u>
6.1	B4.10.2.1	A thorough investigation shall be conducted by the Clinical Program in collaboration with the Collection Facility, and Processing Facility, and other entities involved in the manufacture of the cellular therapy product, as appropriate.
6.1	B5.1.10	<u>Management of toxicities of immune effector cellular therapies, including cytokine release syndrome and central nervous system complications.</u>

Version Number ²	Standard	Change
6.1	B6.3.9	Collection from a donor who does not meet Clinical Program collection safety criteria shall require documentation of the rationale for his/her selection by the transplant <u>recipient's</u> physician.
6.1	B7.10	<u>There shall be policies and procedures addressing the administration of immune effector cells and management of complications.</u>
6.1	B7.10.1	<u>There shall be a consultation with the referring physician prior to initiation of immune effector cellular therapy to review the goal and plan of the treatment.</u>
6.1	B7.10.2	<u>There shall be regular assessment of the recipient to detect complications, including cytokine release syndrome and neurologic dysfunction.</u>
6.1	B7.10.3	<u>There shall be a written plan for rapid escalation of care, increased intensity of monitoring, and relevant workup to address complications.</u>
6.1	B7.10.4	<u>Communication to the clinical staff, intensive care unit, emergency department, and pharmacy shall be timely.</u>
6.1	B7.10.5	<u>The Clinical Program shall have written guidelines for management of complications, including the use of cytokine-blocking agents and corticosteroid administration.</u>
6.1	B8.1.2	<u>There shall be a process to manage investigational cellular therapy products.</u>
6.1	B9.2	<u>The Clinical Program should collect all the data elements included in the applicable CIBMTR Cellular Therapy forms or EBMT forms.</u>
6.1	B9.3	<u>The Clinical Program shall define staff responsible for collecting data and, as appropriate, reporting data to institutional repositories and CIBMTR or EBMT.</u>
6.1	C3.3.2	<u>The Quality Manager should have a reporting structure independent of cellular therapy product manufacturing.</u>
6.1	D3.3.2	<u>The Processing Facility Quality Manager should have a reporting structure independent of cellular therapy product manufacturing.</u>

¹ This appendix does not include minor numbering or reorganization changes that were a result of the substantive changes listed above.

² The effective date of version 6.1 is March 1, 2017.

NHS Greater Glasgow & Clyde

Finance & Planning Committee

4 April 2017

Gary Jenkins
Director, Regional Services

Paper No: 17/??

BONE MARROW TRANSPLANTATION: OPTIONS APPRAISAL

Recommendation

The Acute Services Committee is asked to agree the temporary relocation of BMT Services to 4B QEUH.

At the same time, BMT services should be considered as part of the acute services review of cancer services to deliver a longer term sustainable option that meets both service and environmental considerations.

This recommendation is made on the basis that service delivery considerations require prioritisation over the Infection Control and Prevention Teams concerns on meeting national standards and HPS recommendations.

Purpose of Paper

This paper details the option appraisal of potential locations for the Adult BMT service within NHS Greater Glasgow and Clyde.

It describes the options considered against agreed benefit criteria with clear recommendations on the preferred option to deliver this service both in the short and longer term.

Key Issues to be considered

Key issues that need to be considered are:

- Impact on Staffing arrangements including out of hours cover
- Delivery of environmental standards
- Delivery of service standards
- Strategic fit with longer term direction of cancer services
- Timescale to deliver; and
- Long term sustainability.

Any Patient Safety /Patient Experience Issues

There are patient safety/experience issues with the current arrangements.

Any Financial Implications from this Paper

There are capital works required to implement Option Two.

Any Staffing Implications from this Paper

Yes

Any Equality Implications from this Paper

No

Any Health Inequalities Implications from this Paper

No

Has a Risk Assessment been carried out for this issue? If yes, please detail the outcome.

A service risk assessment of the current arrangement was carried out in 2016. A risk assessment of each option is detailed in section six of this paper.

Highlight the Corporate Plan priorities to which your paper relates

BMT Services are specifically highlighted in the corporate plan.

Date

1st March, 2017

1. Introduction

This paper details the option appraisal of potential locations for the Adult BMT service within NHS Greater Glasgow and Clyde.

It describes the options considered against agreed benefit criteria as well as a risk assessment of each option with clear recommendations on the preferred option to deliver this service both in the short and longer term.

2. Background

The BMT service moved to the QEUH in May 2015 due to concerns that the planned level of support for acutely unwell patients on the Gartnavel General Hospital (GGH) site would be insufficient for such a high intensity speciality and would not meet the JACIE accreditation standards. The move also allowed for an increase of beds from 19 to 24 to support the agreed increase in the national transplant programme. Capital funding of £1million was invested to support enabling works to 4B such as the upgrade air filtration plant.

Unfortunately, the unit had to return to the Beatson West of Scotland Cancer Centre in July 2015 following the identification of air quality issues in the new transplant unit. This return was predicated on it being short-term with further remedial works to be undertaken to improve the air quality in ward 4B, QEUH to acceptable levels. Remedial works were completed by October 2015 and at this time the service began to make plans to move back to QEUH.

The Infection Control Team raised concerns regarding the specification of works that had been completed and requested input from Health Protection Scotland (HPS) at this time. Following the receipt of recommendations from HPS with regard to the required specification (Appendix One), the Infection Control Team advised that the specification did not meet the required environmental standards for a BMT Unit and therefore, they were unable to support return to the QEUH.

A further schedule of works was agreed and scoped in early 2016 requiring additional costs of c. £1m which would deliver further improvements but would still fail to meet the full specification outlined by HPS in the following areas:

- HEPA Filtered Corridors;
- Room Air Changes of 10/hour;
- Room Positive Pressure of 10pa.

It was therefore concluded that whilst further improvements could be made to facilities within 4B, due to limitations of the current plant and lack of space to expand, the fourth floor QEUH could not be configured to meet the full specification of requirements as detailed by HPS/Infection Control.

In the autumn of 2016, a further feasibility study commenced into potential options utilising retained estate on the QEUH site as well as the Laboratory Building and GRI, the study was supported by Currie and Brown. A report was produced in January 2017 detailing a technical and financial analysis of 6 options to be considered as part of the optional appraisal exercise.

A group representing the Clinical Team, Infection Control, Capital Planning, Estates and Regional Service Management met twice in February, 2017 to consider the report, review the options within the

feasibility study and make recommendations on the options to the Board. The membership of this group is detailed in Appendix Two.

3. Current Service

NHS Greater Glasgow and Clyde is commissioned by National Services Division to provide all adult donor stem cell transplantation for the population of Scotland. The national service covers both stem cell donation from family members and unrelated donors. The SLA value in 2016/17 was £7,904,092 for 70 transplants. This is proposed to increase to £8,114,359 for 73 in 2017/18.

The West of Scotland Haemopoietic Stem Cell Transplant Service was established in 1980, when the first sibling donor transplant was performed. Autologous stem cell transplantation was introduced in 1982 and the use of unrelated donors for allogeneic transplant from 1988. From 2006, the Service was designated to provide a National Service for alternative donor transplantation, which includes volunteer unrelated, cord blood and haplo-identical donors.

In 2012, NSD performed a review of adult allogeneic transplant provision in Scotland. This concluded that there should only be a single centre providing allogeneic haemopoietic stem cell transplantation in Scotland and that Centre should be in Glasgow. The Service started taking all the sibling donor transplants from Edinburgh and Aberdeen in 2015.

The review had suggested that the number of patients being transplanted in Scotland was less than elsewhere in the UK and predicted 75 patients a year should be receiving allogeneic transplants, increasing to 85 p.a. It is expected that transplant activity will increase to this level and possibly beyond short to medium term. It was anticipated that the Service would move to the new QEUH in summer 2015 and would have more beds to accommodate the predicted increase in activity.

Transplant numbers are predicted to continue rising. This is because the incidence of haematological malignancy is rising in the population and also increases with age. Transplant outcomes have improved significantly in the past few years for older patients and so, the median age of patients at the time of transplant has also risen. In addition, the improvement in outcome for transplants using haplo-identical donors broadens, meaning these are being utilised in patients who otherwise would not previously have had a donor option.

Currently the unit is performing around 70 allografts per year, the agreed level of activity with NSD is 70 allografts for 2016-17, and 73 for 2017-2018. In addition, the unit performs almost all the autologous transplants for the West of Scotland, currently around 90 transplants per annum, which is also increasing (~60 in 2015, 80 in 2016). This activity is also likely to continue to rise.

4. Option Appraisal

The option appraisal was conducted over two meetings in February 2017. The first meeting was to agree the options to be considered as well as benefits criteria and weighting. The second meeting then proceeded to scoring of the agreed options to provide a ranking of the available options.

4.1 Options Considered

A long list of 8 options was included in the feasibility study, and these were discussed in depth at the Group's first meeting. The capital cost of the options range from £0 to approx. £20m, however, the group's appraisal did not take cost into account, using the preferred Capital Investment Manual methodology of Weighted Benefits Scoring.

At the initial meeting, the Group agreed that four of the options were not feasible at all, based on the findings of Currie and Brown.

This left four options to take forward to scoring:

- remain at BWOSCC;
- return to Level 4 QEUH;
- relocate to the roof of the existing QEUH maternity building;
- relocate to the Institute of Neurological Sciences' Neurology Building at QEUH.

No	Description	Comments
1.	Remain at BWOSCC	Would require significant changes to level of clinical support on site
2.	Return to QEUH Level 4	Unlikely to be a long term option Quality of build environment is main issue
3.	QEUH Maternity roof	Difficult to sustain services during construction, but technically feasible
4.	Neurology Levels 1 and 2	Only technically feasible on paper
5.	Neurology Ground and 1st Floor	Only technically feasible on paper Significant concerns that building could never be fit for purpose
6.	Neurology Ground Floor with external extension	Only realistic Neurology option Difficult, but feasible
7.	QEUH Laboratory roof	Feasibility report indicates that building cannot support extension
8.	St Mungo Building, GRI	Only technically feasible on paper Not feasible from service delivery point of view

4.2 Benefits Criteria and Weighting

At the initial meeting, the group also agreed the benefits Criteria, against which the proposals would be ranked.

No	Description	Definition
A.	Improves the patient journey	Services should be delivered on as few sites as possible to minimise the need for patient and carer travel. The site(s) should be easily accessible with good patient/carers facilities.

No	Description	Definition
B.	Staffing	The extent to which there is adequate safe staffing, both within the unit's staff complement and within other services, e.g. Hospital at Night/resident on-call support.
C.	Meets published/recognised environmental standards	The extent to which the option satisfies both SGHD guidelines on Infection Control and other technical standards (SHTM, HSE, etc). This will take into account the ability to manage the risk associated with not meeting the standards, and any need for derogations.
D.	Meets published/recognised service standards	The service will meet standards set by JACIE and within the NSD service level agreement, and meets BSH Level 3. This includes immediate 24/7 access to the full range of acute services required to support patients who undergo stem cell transplant, including ITU-level critical care services and specialist support and review by other clinical teams.
E.	Minimises service disruption	The extent to which clinical services can be maintained during any required construction and/or implementation phase.
F.	Strategic fit	Links to national, regional and local clinical strategies for delivering cancer services, but with specific reference to wider GGC discussions on future location of BWOSCC and the configuration of haematology services.
G.	Timescale to deliver	There is a clinical urgency to make a decision on the location of the service.
H.	Long-term sustainability	The extent to which the facility improves the current and future capacity to deliver appropriate services to the population of Scotland, in line with ongoing planned expansion.

Prior to completing the benefits matrix, there had been two separate criteria identified for *Clinical Adjacencies* and *Meets Service Standards*:

Description	Definition
Delivers clinical co-dependencies and adjacencies	Having immediate 24/7 access to the full range of acute services required to support patients who undergo stem cell transplant, including ITU-level critical care services and specialist review.
Meets published/recognised service standards	The service will meet standards set by JACIE and within the NSD service level agreement, and meets BSH Level 3.

Whilst completing the Benefits Matrix to agree the weighting to be given to each criteria, the group agreed that the content of point A was encompassed within the service standards, particularly JACIE, referenced in point E, and that these two criteria should be amalgamated under *Meets Service Standards*.

Following identification of Benefit Criteria, the Benefits Matrix was completed, in which individual criteria are compared against each other.

The results were:

		A	B	C	D	E	F	G	H
Improves Patient Journey	A		B	C	D	A	F	G	H
Staffing	B			B	B	B	B	B	B
Environmental standards	C				D	C	C	C	H
Service standards	D					D	D	D	D
Minimises disruption	E						F	G	H
Strategic fit	F							F	H
Timescale to deliver	G								H
Sustainability	H								
		Improves Patient Journey	Staffing	Environmental standards	Service standards	Minimises disruption	Strategic fit	Timescale to deliver	Sustainability

This represented the majority decision of those in the room at the time of the exercise.

The identified benefit criteria were therefore ranked as follows:

Criteria	Score	Rank
B Staffing	7	1
D Service standards	6	2
H Sustainability	5	3
C Environmental standards	4	4
F Strategic fit	3	5
G Timescale to deliver	2	6

A	Improves patient journey	1	7
E	Minimises disruption	0	8

Following the scoring of the Benefits Matrix, *Minimises Service Disruption* scored 0. It was agreed at the Options Scoring meeting on Monday 20 February 2017 that this would be dropped from the scoring process.

Converting this to weighted scoring, this left the options with the following weights:

No	Description	Score
A.	Improves the patient journey	4
B.	Staffing	25
C.	Meets published/recognised environmental standards	14
D.	Meets published/recognised service standards	21
E.	Minimises service disruption	0
F.	Strategic fit	11
G.	Timescale to deliver	7
H.	Long-term sustainability	18

4.3 Option Scoring

The second meeting held was to agree the scoring of each option against the weighted benefits criteria with the membership of the scoring team detailed in Appendix Two.

Each member of the scoring team agreed to provide an individual score from 1-10 which would then be collated to provide an average.

OPTION 1: REMAIN AT BWOSCC

Option one scored low against ability to meet service standards. There are internationally agreed Standards for the staffing, facilities and management for transplant provision, inspected in Europe by JACIE. The Glasgow service was accredited in 2011, but this has now lapsed as the Beatson-based unit cannot meet the necessary Standards for the provision of critical care. Likewise, as option one would involve the continued split of outpatient services on QEUH and inpatients on BWoSCC, it scored low against improvements to the patient journey.

Benefit criteria		Weight	Score	Weighted score
1	Improves Patient Journey	4	4	14
2	Staffing	25	6	150
3	Environmental standards	14	8	109
4	Service standards	21	1	21
5	Minimises disruption			
6	Strategic fit	11	5	54
7	Timescale to deliver	7	9	64
8	Sustainability	18	2	36
Total		100		448

Individual scores given were:

				Service Clinicians			Infection Control		
Benefit criteria		IP	MM	DI	MC	GM	TW	SM	TI
1	Improves Patient Journey	4	4	3	3	3	4	5	5
2	Staffing	6	6	6	6	6	6	6	6
3	Environmental standards	8	8	7	7	7	8	8	8
4	Service standards	1	1	1	1	1	1	1	1
5	Minimises disruption								
6	Strategic fit	5	5	5	5	5	5	5	5
7	Timescale to deliver	9	9	9	9	9	9	9	9
8	Sustainability	2	2	2	2	2	2	2	2

The two clinical groups, the service team and the Infection Control team, evaluated this option only slightly differently, with service clinicians feeling that split-site working deserved a lower rating due to sub-optimal patient care caused by the requirement to transfer patients off site as well as having inpatient and outpatient services split over two sites.

OPTION 2: QEUH, LEVEL 4B

Option two was felt to deliver both an improved patient journey with the consolidation of services onto one site and the most likely to enable the service to meet their specific standards. However, option

two did not score well against criteria to meet environmental standards for the reasons identified above, nor was it felt to be a sustainable option for the longer term.

Benefit criteria		Weight	Score	Weighted score
1	Improves Patient Journey	4	7	25
2	Staffing	25	9	225
3	Environmental standards	14	2	29
4	Service standards	21	8	171
5	Minimises disruption			
6	Strategic fit	11	5	54
7	Timescale to deliver	7	6	43
8	Sustainability	18	3	54
Total		100		600

Individual scores given were:

				Service Clinicians			Infection Control		
Benefit criteria		IP	MM	DI	MC	GM	TW	SM	TI
1	Improves Patient Journey	7	7	7	7	7	7	7	7
2	Staffing	9	9	9	9	9	9	9	9
3	Environmental standards	1	3	3	3	3	1	1	1
4	Service standards	8	8	8	8	8	8	8	8
5	Minimises disruption								
6	Strategic fit	5	5	5	5	5	5	5	5
7	Timescale to deliver	6	6	6	6	6	6	6	6
8	Sustainability	3	3	3	3	3	3	3	3

OPTION 3: MATERNITY BUILDING, QEUH

Benefit criteria		Weight	Score	Weighted score
1	Improves Patient Journey	4	5	18
2	Staffing	25	7	175
3	Environmental standards	14	9	129
4	Service standards	21	6	129
5	Minimises disruption			
6	Strategic fit	11	3	32
7	Timescale to deliver	7	1	7
8	Sustainability	18	7	125
Total		100		614

Option three scored well against criteria to meet environmental standards given it would be purpose built to the required specification. However, there were concerns regarding strategic fit in terms of the longer term strategy for cancer services as well as the ability to adequately staff the unit e.g. Hospital at Night given the relative distance to the main Hospital.

The group agreed a consensus score against each of the criteria.

OPTION 4: GROUND FLOOR + EXTENSION, INSTITUTE OF NEUROLOGICAL SCIENCES

Benefit criteria		Weight	Score	Weighted score
1	Improves Patient Journey	4	5	18
2	Staffing	25	7	175
3	Environmental standards	14	9	129
4	Service standards	21	6	129
5	Minimises disruption			
6	Strategic fit	11	3	32
7	Timescale to deliver	7	1	7
8	Sustainability	18	7	125
Total		100		614

The group again agreed a consensus score against each of the criteria and option four therefore, scored identical to option three for the same reasons.

5. Ranking of Options

The scoring of options resulted in both options three and four ranking first with a score of 614 with option two scoring 600 and therefore, a very close second in terms of non financial benefits criteria. Option one scored 448 and was therefore, the ranked last by a clear margin.

6. Risk Assessment

There are a number of potential and actual risks associated with each of the four options in the following areas:

- Clinical;
- Infrastructure;
- Infection Control/Environmental;
- Patient Experience;
- Service Capacity;
- Accreditation Process;
- Strategic Direction.

Each option presents different risks as identified below. There are additional measures that could be taken to mitigate the risk.

OPTION 1: REMAIN AT BWOSCC

Clinical

The service completed a risk assessment which was submitted to the Strategic Management Group in 2016.

The service is admitting patients for an elective procedure in the knowledge that around 10% of them will require critical care levels that are not available on the Gartnavel site. This is contrary to current quality standards required for HSCTS in NHS England and for JACIE Accreditation and was the major drive for the service to move to the QEUH in 2015. This has also been highlighted by the BWOSCC Future Steering Group.

Whilst of huge value overall, the provision of a High Acuity Unit/Critical Care Outreach service on the Beatson site is of limited benefit to the BMT transplant population. The majority of these patients are being treated with curative intent and therefore will be for full supportive care, including ventilation and inotropes if needed. HAU can deliver level 1 care but if a patient is deteriorating and predicted to require level 2 care or beyond, they need to be transferred early to the critical care service at QEUH before that requirement is reached. This means that some patients are transferred, who do not ultimately deteriorate to level 2. It is also important to ensure that patients have recovered sufficiently and that their condition is stable before transferring them back to the BWOSCC when they could have been sent back to a QEUH ward at an earlier date. If the BMT unit was on the same site as critical care services, patients would not require pre-emptive transfer and delayed returns with reduced requirement for critical care beds. The BMT service is the highest user of the HAU/CCO service, with 46 transfers since returning to the BWOSCC 18 months ago. Of particular concern is that 10 patients required more than one transfer, one patient being moved four times during their inpatient stay. Patients also have to be transferred to QEUH if they require specialist opinion and or interventions such as endoscopy, cystoscopy, ureteric stent placement.

BMT in patients on the QEUH site are placed in wards whose staff are unaware of the requirements and complexities of BMT patients. They struggle to manage the demands of unfamiliar problems even in the critical care setting, due to high numbers of unfamiliar drugs, frequently given as multiple IV infusions. There have been several instances of patients not getting prescribed drugs in this

situation. BMT patients require frequent infection and drug level monitoring which can at times be missed either due to failure to request or incorrect samples being sent when they are the QEUH.

There is no dedicated transplant nursing, pharmacy or AHP staff on site at QEUH and it is extremely challenging to ensure optimal management for these complex patients. If the BMTU was on the same site there would be far greater input from the multidisciplinary BMT team to patients admitted to critical care.

Some medical and surgical wards are not capable of managing patients with central access so that peripheral venepuncture and cannulas are used unnecessarily if nursing staff are untrained in the use of these lines.

Certain types of transplant bring a high risk of cytokine storm with requirement for intensive support for both circulatory and respiratory systems and it is not safe to have these patients on the BWOSCC at certain times during their inpatient stay. Patients have been electively transferred to the QEUH critical care facility for observation and, if required critical care support, at the time of highest risk. BMT nursing staff have been seconded as chemotherapy needs to be given as part of the management, impacting on nursing numbers available for the BWOSCC ward.

Mitigation

In an effort to mitigate against the risks identified above, patients who are transferred to the QEUH site are reviewed daily by a member of the BMT consultant team. They direct the care of the patient and try to ensure that all appropriate tests, drugs etc. are arranged and available. They can be contacted via switchboard or mobile phone at any time.

Nursing staff who attend the BMT clinics at the QEUH on Monday, Tuesday and Thursday visit patients admitted to the QEUH to provide a familiar face and help the nursing staff with any problems they have. One of the consultant clinical psychologists visits any patients who have been transferred to the QEUH.

There are information sheets for the different drugs detailing how they should be administered and contact details for the BWOSCC ward for advice. A supply of any unusual drugs are transferred with the patient.

BMT outpatients from GGC, who present with symptoms that might indicate they are having GI blood loss, respiratory distress or cardiac symptoms although BMT complications can also cause similar symptoms, have to be told to go to their local ED for assessment as it is not safe to see them at the BWOSCC due to lack of critical care support.

Infrastructure

The BWOSCC Unit is now 10 years old and it is becoming more common for rooms to be closed for repair for water leaks, flood damage etc. The HEPA filtration plant has no back up and cannot be switched off for maintenance. With increasing age comes concern about risk of catastrophic failure with loss of a safe environment.

Patient Experience

NHS GGC provides the national service for patients which by definition have a life-threatening disease and are receiving treatment which could also be life-threatening. Patients and their families are coming from all over Scotland. Many will have formed strong attachments to their referring unit following prolonged stays and find it hard to make the transition to a new team. This formation of a relationship with the BMT team can be disrupted by the transfer. Psycho-social care and support for patients and their families is critical, during what is likely to be the most stressful experience of their lives, potentially a long way from home and their own support network. This is an integral part of the service provided, but cannot be delivered effectively when patients are transferred off-site.

A number of patients and their families have felt very isolated at QEUH, during a very traumatic and critical part of their treatment, being moved to an unfamiliar environment, to be managed by unfamiliar staff, who have limited or no experience in transplant.

The following comment is from correspondence from the wife of a patient who recently passed away:

"In total xxx spent 59 nights at the Beatson and 47 nights at QEUH!!!! For 47 nights xxx was nursed by people with no post transplant experience despite the Leaflet 'A patient's guide to Allogenic Bone Marrow Stem Cell Transplant' stating "the nursing staff involved in your care have specialist experience in transplantation"

Several patients have vowed they will not return, even if this is deemed medically necessary. Patients who do not recover sufficiently to transfer back to the BWOSCC have to remain at the QEUH for palliative care.

Service Capacity

It had been planned to increase bed capacity from 19 to 24 beds to accommodate anticipated growth in activity as the designated single centre for NHS Scotland. As the service remains in BWOSCC, this has not been possible and capacity is limited to 20 beds.

Every effort is made to admit a patient once they are fit for transplant and a donor has been identified. However, some patients do have to receive additional therapy or are not admitted as promptly as they might be, particularly those who have a relatively indolent disease eg. MDS, myelofibrosis. It is very difficult to quantify this number, but probably 5-6 patients per year are admitted 2-3 months later than they needed to be, because of lack of bed space. So far no patient has developed accelerated disease during the delay, however, it could occur with any of these individuals.

It is often not possible to admit patients to a BMT bed, who have been transplanted and developed complications requiring specialist care. All patients are managed in their local hospitals whenever possible, but some should be transferred and are not due to lack of beds.

Accreditation

There is an expectation from commissioners that the nationally commissioned service will be JACIE accredited. Whilst the service will meet environmental requirements as outlined in appendix five, it is unlikely to be accredited due the lack of support services including critical care on site.

OPTION 2: QEUH, LEVEL 4B***Infection Control/Environmental***

As noted, the facility in 4B QEUH does not meet the standards set out by SHTM 03-01 (Appendix six) for neutropenic rooms or HPS guidance and therefore, the main concern is that of airborne infection particularly invasive fungal infection (IFI) due to organisms such as aspergillus and zygomycosis due to air quality. Based on published literature, mortality rates in outbreaks related to construction or demolition in patients with Haematological malignancies are quoted at 57.6%. Concentrations of aspergillus species below 1 colony forming unit/m³ are sufficient to cause infection in high risk patients.

Currently, the BMT Unit in NHS GGC's Royal Hospital for Children does not meet the standard either however, the rooms do have a positive pressure of 10 PA hepafiltration and have anterooms. It has been agreed to upgrade four of these rooms to meet the full standards.

Mitigation

Appendix three provides benchmarking of BMT units across the UK. NHS GGC's Lead Infection Control Doctor has contacted two of the centres – Nottingham and Devon (two adult units with a specification that does not meet HPS guidance) to ascertain their infection rates and what if any mitigating actions they have in place.

Improvements to the environment in ward 4B are achievable with additional capital expenditure including the sealing of the bathroom ceilings and creation of a double door entry system. Further measures would include introduction of twice daily cleaning of the ward as well as the use of portable HEPA filtration units in the corridors.

There is now very effective anti-fungal prophylaxis and sensitive screening tests, which can be used to manage risk in this patient population. A strategy of effective prophylaxis and confining patients to their rooms with the ward closed to all through traffic will minimise the risk of acquiring fungal infection whilst an inpatient.

A robust monitoring regime as detailed in Appendix Four and which is currently in place in the current BMT unit in B8/9 at BWoSCC.

Infrastructure

In addition to the fact that ward 4B does not provide the required specification for BMT services, it is also served by only one air handling plant. As a consequence, there is no way to carry out maintenance\service PPM\annual verification without shutting down the ventilation plant, which would affect all isolation rooms served by the single air handling unit. This would require the ward to be vacated during each period of planned preventative maintenance.

Mitigation

The recently proposed upgrade works to ward 4B includes the addition of a standby air handling unit, albeit of reduced capacity which would mitigate against the concerns identified above. This would require significant capital investment as previously identified.

Accreditation

There remain a risk to JACIE accreditation given the infrastructure/environmental risks highlighted above. That said, JACIE does not specify environmental requirements to the standard previously provided by HPS as outlined in Appendix five. Therefore, it is anticipated that provided the monitoring regime does not identify any issues, that this should provide sufficient evidence that this requirement is being met.

OPTION 3: MATERNITY BUILDING, QEUH

Clinical

There are concerns that the risk of this option is around the ability to safely staff the unit 24/7. The BMT service does not have their own junior medical team and is instead supported by the BWoSCC. Should services relocate, they will require to be covered by the Hospital at Night team as is currently the case. Whilst this is likely to be deliverable within the main ward block of QEUH, there is concern that the service will not be safely covered in an option that would see them relocate outwith the main QEUH ward block.

Further, any option that requires a significant build is unlikely to be delivered within a timeframe of less than two – three years. The clinical risk associated with remaining on the BWoSCC site for this period of time has already been highlighted above.

Strategic Direction

There is concern with the strategic fit of this option with the long term direction of cancer services. Work is ongoing regarding the long term direction of cancer services. The preference would be to remain co-located with cancer services in the future but capital investment in this option may preclude this in the future.

OPTION 4: GROUND FLOOR + EXTENSION, INSTITUTE OF NEUROLOGICAL SCIENCES

The risks identified with this option are identical to those with option 3.

7. Conclusions

Whilst Options three and four clearly scored the highest with regard to delivery of environmental standards, there are concerns regarding the staffing, strategic fit and timescale for delivery.

Given the close scoring between options two, three and four against non financial benefits criteria the group discussed option two as an interim solution for a time limited period.

Whilst option two would not provide the required environmental standards, benchmarking across the Centres in the UK has demonstrated that only those services that have moved into purpose built facilities are currently delivering this standard as outlined in Appendix Three.

8. Recommendations

The Acute Services Committee is therefore, asked to consider option two as an interim solution and support the relocation of BMT Services to 4B QEUH. To support the move, it is proposed that further refurbishment works be commissioned as detailed in the risk assessment. Thereafter, a period of air

quality monitoring should be undertaken as outlined in Appendix Four. To enable this, the ward will need to be vacated and positive pressure switched on which will preclude the use of the ward for medical surge capacity.

At the same time, BMT services should be considered as part of the acute services review of cancer services to deliver a longer term sustainable option that meets both service and environmental considerations as detailed in Appendix one.

This recommendation is made on the basis that service delivery considerations require prioritisation over the Infection Control and Prevention Teams concerns on meeting national standards and HPS recommendations.

Appendix One

Recommendation	To allow the provision of a protective environment for patients within the bone marrow transplant unit (Ward 4B) • The rooms must be positively pressured at 10 pa • ALL air entering the room must be via the HEPA filter • The HEPA filter should as a minimum be E12 (H13) and located within the supply air diffuser • The rooms must be sealed and no air which has not passed via the HEPA filter should access the room • A strict protocol which minimises the length of time the door is opened and reduces air entry via an open door is required. • There must be a continuous pressure monitoring system for each room which alarms and gives an early indication of a pressure drop within the room • Bedroom Air changes of 10 ACH must be achieved • The walls and ceilings within the rooms and ensuite must be sealed. • All room services must be sealed • All service access hatches within the bedrooms/ensuite must be sealed • The pentamidine room must be negatively pressured and comply with health and safety legislation • There must be at least one room available in the critical care unit capable of providing the same level of protection as those proposed in ward 4B • HPS will continue to co-ordinate and provide support with this issue and subsequently the Children's unit and additional areas of ventilation concern (Critical care, ID Unit, theatres) • HPS will co-ordinate and provide support a required relating to water control and testing in this unit

Manchester Children's Hospital	Y	Y	N	N	N	Y	No air pressure monitoring of any rooms just a general alarm should the AHU or booster fan fail. This is displayed at the nurses' station via a red LED showing airflow fail.	N	TOILET ONLY	Particle counts to ISO 14644 Class 5 and 6	ICU + HDU	

Appendix Four**SBAR – Air sampling , BMT units**
Dr T Inkster 09/03/17

Situation	Air sampling has been performed on a monthly basis in B8/9 as a quality assurance check. There is no requirement as such to air sample and no agreed standards or guidance for interpretation of air sampling for UK BMT units. Practice is variable across the UK and three units which meet a high ventilation specification do not routinely air sample. The ventilation spec in 4B, QEUH is less than that of B8/9 therefore it is unclear what interpretative criteria to apply and what actions to take when results are elevated. Currently medical patients are housed in 4B with positive pressure ventilation turned off
Background	Particle counts and air sampling are undertaken in B8/9 unit on a monthly basis. Particle counts < 1000 are deemed acceptable limits (ISO standard for clean rooms) and fungal air sampling results <0.1 CFU/m³. Particle count results are available in real time however it is important to note the environmental conditions while sampling. Particles are not just fungus or bacteria but can be skin, dust, hair, cosmetics etc The commonest explanation for high particle counts are people in the vicinity of sampling or failure of the sampling to be carried out remotely. Particle counts can be higher when rooms have just been cleaned . If the aforementioned factors have been excluded high particle counts can alert infection control teams early to possible air quality issues and fungal contamination. They cannot be used in isolation as an accurate indicator of air quality. Air sampling results and fungal culture take 7 days to initial identification and a further 7 days for species identification .
Assessment	Literature review; <u>Indications for air sampling</u> Indications for air sampling are listed in the table below from Morris <i>et al.</i>¹ Note that regular maintenance is considered more important than air sampling. Air sampling is only one parameter of many with regards to assessment of the efficacy of a ventilation system.

Table I Objectives of air sampling

To correlate outbreaks of invasive aspergillosis with hospital construction/demolition

To identify potential sources of nosocomial aspergillosis, eg. potting soil, damp ceiling voids, damp fire proofing material, carpeting, etc.

To predict environmental spore contamination from outside sources

To identify defects/breakdown in hospital ventilation/filtration systems*

To monitor cleaning procedures that may release bursts of airborne *Aspergillus conidia*

To determine the efficacy of HEPA filters in laminar flow facilities

To monitor efficacy of procedures to contain hospital building work from hospital wards and other areas where high-risk patients are managed

To determine level of contamination prior to initial occupancy of special controlled environments

*regular engineering maintenance of the air supply system (whether HEPA-filtered or not) is more important than regular air sampling

Result interpretation

Interpretation of results can be difficult. The table below gives some recommendations.¹ For BMT rooms the HEPA filtered air value would apply i.e. <0.1 CFU/m³

Table III Interpretation of air sampling data and recommendations

Levels of fungal spores vary by several orders of magnitude during the course of a day due to:

- Activity levels in any one particular area
- Fluctuations in temperature
- Fluctuations in humidity
- Fluctuations in air flow
- Changes in light level

A single air sample will often underestimate the fungal contamination in the air: multiple air sampling has to be performed

No strict numerical guidelines are available which are appropriate for assessing whether the contamination in a particular location is acceptable or not but the following threshold levels have been recorded:

Outdoor air: total fungal count: 10³ to 10⁵ CFU/m³

Aspergillus: 0.2–3.5 conidia/m³

Note: seasonal variation recognised

HEPA filtered air (> 95% efficiency and > 10 air changes per hour): < 0.1 CFU/m³

No air filtration: 5.0 conidia/m³

Construction/defective ventilation: 2.3–5.9 conidia/m³

If total fungal count exceeds 1.0 CFU/m³ on several occasions the air systems or procedural practice in patient areas requires intensive evaluation.

There is no agreed level at which the risk can be numerically defined for Invasive Aspergillosis. Vonberg et al state that concentrations below 1 cfu/m³ were sufficient in high risk patients.² It is best to conduct a series of samples over time to detect trends.³

Burst phenomenon

Understanding the burst phenomenon of fungi particularly *Aspergillus* is important. Spores can be released in bursts and the difficulty is capturing these bursts. No amount of air sampling will yield a preventative response to this phenomenon.⁴ Negative air sampling may provide false reassurance. Striefel et al suggest that the emphasis should

	be on maintaining environmental controls and minimising the in house release of spores ⁴
Recommendations/ Conclusions	1. In the absence of any definitive guidance the BOC parameters could be applied to level 4B, QEUH i.e. particle counts <1000/m³, fungal counts <0.1/m³ 2. Air sampling has been performed on a monthly basis in BOC as a quality assurance check, however, this would not be an accurate indicator of air quality in an area where we know that the ventilation is of a lesser specification. The specified parameters are less reliable in an area where we expect to encounter higher counts. 3. Difficulties are likely to arise in the management of sustained elevated particle counts and repeated fungal growth with no obvious source should they occur – this is a possible scenario given the ventilation specification in 4B and the inability to HEPA filter all air entering the unit 4. Negative air sampling may provide false reassurance due to the burst phenomenon 5. To enable a period of monitoring prior to BMT patients moving in to 4B medical patients would have to be vacated and the positive pressure reinstated. 6. Ideally a minimum period of 4-6 weeks monitoring prior to BMT patients occupying the ward should be undertaken

Appendix Five

The sixth edition of the *FACT-JACIE International Standards for Hematopoietic Cellular Therapy Product Collection, Processing, and Administration* have been published and became effective from June 2015.

The standards are available at: <http://www.jacie.org/standards/6th-edition-2015>

The applicable standard for air quality is B2.1. **Both QEUH and BWOSCC meet this standard.**

B2.1 There shall be a designated inpatient unit of appropriate location and adequate space and design that minimizes airborne microbial contamination.

Explanation:

Clinical unit facilities may vary among centers. Variability may reasonably be based on a number of factors, including the number and/or type (autologous or allogeneic) of transplants performed, the patient case mix, the graft source, epidemiological factors influencing the prevalence of opportunistic infections, potential economic factors, and an increasing use of ambulatory facilities for transplantation.

This standard is not meant to imply that every clinical unit must have laminar airflow available, but HEPA filtration with positive pressure is recommended for high risk patients. If non-HEPA filtered rooms are used for lower risk patients or if there is a shortage of HEPA filtered rooms, the SOP(s) on infection control, biosafety, and chemical and radiological safety should indicate how allocation of rooms is prioritized. Further, auditing of airborne microbial infections in non-HEPA rooms should be performed as part of the QM Program.

Evidence:

The inspector will tour the inpatient unit during the on-site inspection. Because different patients have different infection control needs, the Clinical Program must have policies and procedures that define infection control requirements based upon differing patient conditions and room configurations. The type of air handling should be documentable from a facilities management office. An SOP detailing alternatives in case there is a shortage of isolation rooms; steps for preventing and controlling specific healthcare-associated infections, such as MRSA, C. Difficile and community respiratory virus infections; and procedures for monitoring airborne infections will provide evidence of compliance.

Signs posted around the clinical unit and the behavior of the staff consistent with expectations for the type of infection control described in the policies and procedures demonstrate compliance with this Standard. If there are renovation or construction projects underway, the appropriate environmental controls must be present. The risk of spread of communicable disease agents must be minimized in any setting where patients could reasonably be expected (including dialysis or intensive care units). Care should be taken that the ventilation from other isolation rooms (where

infected patients may reside) does not pass through the rooms used for HPC patients. Evidence of compliance with this Standard will require preinspection documentation of infection control policies, specifications of air handling, and floor plans.

When an accredited Clinical Program is to be relocated, qualification and validation must be performed to confirm the new space meets the Standards. The requirements for maintaining FACT accreditation in the event of relocation are outlined in the FACT accreditation policies, available on the FACT website.

The Clinical Program is expected to submit a description and floor plans of the new facility, QM documents, and an expected relocation date. If a JACIE-accredited facility intends to relocate, the program should submit plans and descriptions of the relocation to the JACIE office. Most relocations will be assessed during regularly scheduled inspections or interim audits; however, if there are any concerns with the information submitted by the facility, a relocation inspection may be necessary.

Example(s):

HEPA filtration with positive pressure is recommended for high-risk patients, but is not required for every unit. Single patient rooms should be located on a patient care unit where infection control policies can be implemented. Portable, industrial-grade HEPA filters may be available to accommodate vulnerable patients in case of a shortage of rooms.

Visitors should receive information concerning communicable infections. Signs posted to inform the public about visitation restrictions could also include information about incubation periods and risks of live vaccines.

In ambulatory settings, patients may be accommodated in a hostel, hotel, or home-based setting for periods of the transplant with frequent day case review and potential rapid inpatient admission. Clinical Programs should share criteria with these facilities regarding practices to prevent the spread of communicable infections.

The following standard can be **met at QEUH but not at BWOSCC**:

B2.5 There shall be provisions for prompt evaluation and treatment by a transplant attending physician available on a 24-hour basis.

Explanation:

A transplant attending physician must be available at all times to manage transplant recipients. The transplant attending physician does not necessarily need to be the only health care provider on call nor be the first to see any patient requiring attention.

Evidence:

An on-call schedule should be available for inspector review. Inspectors may choose to test attending physician availability by activating the on-call schedule during the period of the on-site inspection.

Example(s):

Numerous post-transplant complications may require prompt attention, such as central venous line-associated bacterial sepsis. If needed because of distance to the in-patient facility or for other reasons, a protocol should exist for outpatient facilities to contact emergency medical services if needed for prompt care (for example, 911 in the U.S. or 112 in the EU).

Notes on GGC performance:

While a transplant physician is on-call 24/7 for attending the BWOSCC, it is not possible for the team to cover two sites and, as described above, transplant support for patients in critical care is delivered predominantly by phone, and not in person. While in ITU, patients do not have direct access to transplant physicians, nurses or specialist pharmacists. This standard would be met if the Transplant Unit and critical care facilities were co-located.

The following standard can be **met at QEUH but not at BWOSCC**:

B2.13 There shall be an intensive care unit or equivalent coverage available.

Explanation:

The Clinical Program must have documentation that there is ready access to an ICU or equivalent coverage in an immediate fashion for its patients when appropriate. This requires the ability to provide multisystem support including assisted respiration. Ordinarily, this would be within the institution but contractual arrangements with another institution may be considered if transfer procedures are in place to ensure prompt service and patient safety.

Outpatient facilities must document a plan for immediate transfer to an ICU, emergency department (ED), or inpatient unit if clinically warranted. The outpatient plan for providing inpatient care if needed should be discussed with the patient regardless of the type of outpatient setting (e.g., home, day unit, hotel, etc.). The outpatient plan should address specific needs of transplant recipients, such as the need for isolation protocols for immunocompromised patients, transfer to transplant-designated units related to clinical indications, and transplant-specific discharge plans.

Notes on GGC performance:

The key phrase within the standard is 'ready access [...] in an immediate fashion.' While there are currently transfer arrangements in place, the standard envisions that patients will still be managed by appropriately trained transplant physicians, as per B2.5 above. This level of care cannot be provided while the service is provided by two non-adjacent sites.

The following standard can be **better met at QEUH than at BWOSCC**

B3.9.1 The Clinical Program shall have access to certified or trained consulting specialists and/or specialist groups from key disciplines who are capable of assisting in the management of patients requiring medical care, including, but not limited to:

B3.9.1.1	Surgery
B3.9.1.2	Pulmonary medicine
B3.9.1.3	Intensive care
B3.9.1.4	Gastroenterology
B3.9.1.5	Nephrology
B3.9.1.6	Infectious disease
B3.9.1.7	Cardiology
B3.9.1.8	Pathology
B3.9.1.9	Psychiatry
B3.9.1.10	Radiology.
B3.9.1.11	Radiation oncology with experience in large-field (e.g., total body or total lymphoid) irradiation treatment protocols, if radiation therapy is administered.
B3.9.1.12	Transfusion medicine
B3.9.1.13	Neurology
B3.9.1.14	Ophthalmology
B3.9.1.15	Obstetrics/Gynecology
B3.9.1.16	Dermatology
B3.9.1.17	Palliative and end of life care

Explanation:

In addition to the specialties specifically listed in these standards, Clinical Programs should also have access to other specialists directly related to the diseases being treated, such as metabolic diseases or immunodeficiencies.

Notes on GGC performance:

While telephone advice is available from all of these specialties within BWOSCC, and Ophthalmology is available on-site at Gartnavel campus, part of the rationale of designating NHSGGC as the single national centre for allograft transplantation in Scotland was to achieve co-location with these specialties on the QEUH campus.

Further guidance which applies to the BMTU

Haematological cancers: improving outcomes

NICE guideline [NG47]

Published date: May 2016

Available at: <https://www.nice.org.uk/Guidance/NG47>

	BWOSCC	QEUH
Centre size		
Haematology units that care for adults and young people who are receiving high-intensity chemotherapy should provide high-intensity (non-transplant) chemotherapy for induction or re-induction of remission to a minimum of 10 patients per year who have new or relapsed haematological malignancies and who are at risk of more than 7 days of neutropenia of 0.5×10^9 /litre or lower.	Y	Y
Isolation facilities		
Inpatient isolation facilities for adults and young people who have haematological malignancies and are at risk of more than 7 days of neutropenia of 0.5×10^9 /litre or lower should consist of a single-occupancy room with its own bathroom.	Y	Y
Consider installing clean-air systems into isolation facilities for adults and young people who have haematological malignancies and are at risk of more than 7 days of neutropenia of 0.5×10^9 /litre or lower.	Y	Y
Ensure that there is provision for direct admission to the haematology ward or other facilities equipped to rapidly assess and manage potentially life-threatening complications of chemotherapy (such as neutropenic sepsis or bleeding) in adults and young people, according to agreed local protocols.	Y	Y
Ensure that there are specific beds available in a single dedicated ward within the hospital with the capacity to treat the planned volumes of patients.	N	Y
Other facilities		
Ensure that there is a designated area for outpatient care that reasonably protects the patient from transmission of infectious agents, and provides, as necessary, for patient isolation, long duration intravenous infusions, multiple medications, and/or blood component transfusions.	Y	Y
Ensure that there is rapid availability of blood counts and blood components for transfusion.	Y	Y
Ensure that there are on-site facilities for emergency cross-sectional imaging.	Y	Y
Ensure that cytotoxic drug reconstitution is centralised or organised at the pharmacy.	Y	Y
Ensure that there is on-site access to bronchoscopy, intensive care and support for adults and young people with renal failure.	N	Y

Notes

- The recommendations apply to young people (16–24 years) and adults (over 24 years) with haematological malignancies who are receiving high-intensity (non-transplant) chemotherapy for induction or re-induction of remission or consolidation
 - They apply to all patients treated within the transplant unit, as patients receive both pre-transplant conditioning regimes and, where clinically required, post-transplant treatment within the unit
- The increasing transplant activity requires additional beds which are not available at BWoSCC (max 19 beds, as opposed to 24 beds within QEUH)
- Patients have to be transferred off-site for ITU care and acute renal failure for dialysis. It is possible to dialyse patients at the BWoSCC, but this would realistically only be for patients with chronic renal failure, already established on dialysis. Bronchoscopy can be performed on site, but most patients requiring this would be too unwell for it to be performed at BWoSCC. In addition, anyone with an acute bleed requiring endoscopy needs to be transferred.

Appendix Six**Recommended air-change rates**

Background

NHS Greater Glasgow and Clyde (NHSGGC) are currently investigating and managing a contaminated water system across the Queen Elizabeth University Hospital (QEUP) and Royal Hospital for Children (RHC) with probable linked cases of bloodstream infections associated with wards 2A/2B RHC. During this investigation it was identified that there was a higher than expected level of Healthcare Associated Incidents (HCAI) linked to wards 2A/2B. The National Support Framework (<http://www.nipcm.scot.nhs.uk/documents/the-national-support-framework-2017/>) was invoked by the Scottish Government HAI/AMR Policy Unit to request Health Protection Scotland (HPS) undertake a review of Ward 2A/2B.

Due to the ongoing water contamination investigation and resultant summary report being prepared by HPS for Scottish Government it was agreed that whilst the review of wards 2A/2B was ongoing the report would not be undertaken until final submission of the water investigation report was completed. The final submission of this report was on 21st December 2018.

Wards 2A/2B RHC is a paediatric haemato-oncology unit, also known as Schiehallion, and houses the National Bone Marrow Transplant (BMT) Unit. The RHC is a 256 bedded childrens hospital which was handed over to the Board on 26th January 2015 with migration of patients occurring between 10th and 14th June 2015 from the previous Yorkhill site. The RHC was fully occupied from 15th June 2015.

All water related issues linked to wards 2A/B are discussed in the water incident report submitted to Scottish Government 21st December 2018 and not within this report. In addition a ventilation review of wards 2A/2B is currently being undertaken and will be covered within a separate NHSGGC report.

Wards 2A/2B closed on 26th September 2018 to allow for a works relating to water contamination to be completed. At this time the opportunity was taken to review the ventilation. Patients were transferred to wards 6A/4B at the Queen Elizabeth University Hospital.

Introduction

Since January 2016 NHSGGC have reported 15 Healthcare Infection Incident Assessment Tool (HIIAT) incidents/outbreaks within wards 2A/2B RHC. Comparative data for this setting (all paediatric hospitals) within NHSScotland identified no reported incidents or outbreaks outwith NHSGGC. The HIIAT allows NHS boards to assess the impact of a healthcare infection incident/outbreak on patients, services and public health and should be used by the Infection Prevention and Control Team (IPCT) or Health Protection Team (HPT) in their assessment of any incident/outbreak within a healthcare setting. In addition it supports a single communication channel for infection incident/outbreak assessment and reporting both internally within an NHS board area and externally to Health Protection Scotland (HPS) and Scottish Government Health and Social Care Department (SGHSCD).

Mandatory HIIAT Green (non-norovirus) reporting for NHS boards was introduced in April 2016; providing a more robust epidemiological picture of incidents and outbreaks across acute healthcare in NHSScotland. A HIIAT assessment is scored Red, Amber or Green according to a four part criteria:

- Severity of illness
- Impact on services

- Risk of transmission
- Public anxiety

Of the 15 HIIATs reported from 2A/2B since 2016 there have been 5 reds, 2 ambers and 8 greens reported to Health Protection Scotland (HPS). Details of the incidents reported are contained in [appendix 1](#). Four of these HIIATs (2 red and 2 green) are attributed to the ongoing water incident. It could be hypothesised that ventilation may have been a contributory factor in several incidents however this cannot be confirmed until a full ventilation review has been completed.

Wards 2A/2B Assessment

Observational assessment walk rounds of wards 2A/2B was undertaken by a Senior Nurse Infection Control from HPS on 18th to 22nd June, 2nd July and 8th August 2018.. During these walk rounds practice and environmental hygiene were observed.

A meeting was held between the Chief Nurse Hospital Paediatrics and Neonatology, Consultant Surgeon and two Nurse Consultants Infection Control (HPS) to discuss ongoing work into central line-associated blood stream infections (CLABSI). This meeting took place on 17th July 2018.

It is noted that overall practice was described as good with no major issues observed or reported. Compliance with standard infection control precautions (SICPS), particularly hand hygiene, use of personal protective equipment and environmental cleanliness was observed to be good. Awareness of infection control practices were high with notable visibility of the local infection prevention and control team (IPCT).

Ward 2A Overview (Floor plan [appendix 2](#))

- Ward 2A consists of 25 ensuite single rooms.
- There are three distinct areas to the ward; the BMT bedrooms, standard rooms and the remaining Teenage Cancer Trust (TCT) and haemato-oncology rooms.
- The main entrance to the ward is through the entrance at the BMT section of the ward .
- Children with haemato-oncology and haematology disorders are the main patient population within this ward.

Ward 2B Overview (Floor plan [appendix 3](#))

- Ward 2B consists of five consultation rooms and two 4-bed-bay areas.
- Ward 2B has a main waiting area at the reception of the ward with a TCT waiting area beside the TCT bay area.
- Ward 2B cares for children with haemato-oncology and haematology disorders on a Monday to Friday day care basis.

Water

A detailed summary report was prepared and submitted to HAI/AMR Policy Unit on 21st December 2018. This summary report documents all the findings from water-related investigations carried out until the decant of patients from Ward 2A/2B.

Ventilation

Work has been undertaken to convert the positive pressure ventilated lobbied rooms (PPVL) used predominantly for bone marrow transplant recipients into specification compliant positively pressured isolation rooms.

Ventilation within these wards is subject to a review by NHSGGC and will be covered in the resultant report. An SBAR covering initial findings has been prepared at the request of Scottish Government (SG) and submitted to SG by NHSGGC (November 2018).

Chilled beams

Chilled beams were noted to have significant level of dust present in two separate rooms (Ward 2A) there was also discolouration to the edges of the ceiling around the supply. This is potentially due to water contamination and was under review by estates department.

Dripping from the chilled beams had been observed by staff on a number of occasions. This was reported to estates and it has been identified that there were no dew point controls on the chilled beams. A dew point control has been fitted to the central system to alleviate the issue.

Temperature

Ward 2A was observed to be very warm and humid on the day of the visit and staff reported this was common for the ward.

HEPA filtration

The corridors within these wards are not HEPA filtered. The previous facility within Yorkhill hospital was reported to have 8 HEPA filtered rooms with all other rooms being conventionally ventilated.

Pressure stabilisers

Pressure stabilisers were noted in the rooms and also to the corridor of all the BMT rooms. There was no noted issue with overall pressures during this time however some of the stabilisers were noted to have no oscillation when the doors were opened.

Air Changes

It is noted from an SBAR prepared by NHSGGC on 12th November 2018 that the single room accommodation has a nominal air change rate of 2.5 air-changes per hour (ACH).

Air flow/pressure

The single rooms are negative to neutral pressure relative to the ward corridor. There is a further potential risk whereby extract air via the ensuite toilets may combine with the air supply passing through the thermal wheel which may result in an increased chance of cross contamination between single rooms.

All aspects of ventilation including the mixing of extract air with air supply and the potential resultant cross contamination risk will be explored as part of the ventilation review by NHSGGC.

Standard Infection control precautions (SICPs)

Compliance with SICPs was noted to be good, including hand hygiene and the use of personal protective equipment. A programme of monthly SICPs monitoring is in place. All SICPs audits reviewed at the time of the visit were of an optimal score. The IPCT undertake environmental audits in line with the agreed NHSGGC IPCT monitoring programme. At the time of the walkround it was reported that both wards had been given a GREEN audit score at the last IPCT audit. Follow up audit results from August 2018 have been reported as 96% (GOLD) for ward 2A and 98% (GOLD) for ward 2B.

Central Venous Line Management

Significant work has been undertaken across RHC relating to line management. A central venous line quality improvement project steering group was formed in May 2017 following a noted increase in line infections. The group collected data on central line-associated blood stream infections (CLABSI) on a week-by-week basis on lines inserted on the RHC site and includes all patients within the haemato-oncology cohort (including those cared for at home, shared with other hospital sites and inpatients). It was reported that the figures for CLABSI (outwith the BSIs identified as part of the water related incident) are reducing. The group is led by the Chief Nurse (RHC) and a consultant paediatric surgeon.

HPS undertook an epidemiological review of all positive blood samples from patients recorded as being admitted to wards 2A/2B and compared these to samples obtained prior to the move from Yorkhill and those obtained from patients in other areas of the hospital. A detailed report on the findings is included in [appendix 4](#).

Summary

Any issues identified during the walkround visits were reported to staff at the time to ensure they were addressed. Overall there were no significant practice related concerns identified and awareness of infection prevention and control by all staff was high. There was a good presence of the infection prevention and control team on both wards with daily visits (Monday to Friday) being undertaken. A joint weekly walkround with infection control staff, nursing staff, facilities and estates staff is undertaken in an attempt for early identification of any issues which require to be addressed.

Based on the ward reviews and the epidemiological data presented in this report it is hypothesised that the increased number of HIIAT reports could all be linked to environmental factors and are not considered to be indicative of poor or compromised practice.

Recommendations

Consideration should be given to:

- The ventilation review underway within wards 2A/2B is completed with the involvement of the IPCT.
- A ventilation review is undertaken in other areas across RHC/QEUIH in particular areas where high risk patients are to ensure compliance with national guidance.
- Issues identified within the ventilation review which are considered by the IPCT to pose an increased risk of cross infection should be addressed and signed off by the IPCT prior to repatriation of the patients.
- High visibility of IPCT within the wards should continue.

- CLABSI work continues.
- IPCT continue to observe infection rates and trigger breaches and report as per HIIAT where required.

Appendix 1: HIIAT Assessments

NHSScotland Incident and Outbreak Summary Ward 2A RHC (January 2016- Dec 2018).

NHS Greater Glasgow and Clyde have reported a total of 10 outbreaks and incidents for the clinical setting paediatric haemato-oncology. Of the 15 incidents and outbreaks HIIAT assessed; 5 were Red, 2 were Amber and 8 were Green. The data is displayed in the tables below providing a breakdown of the outbreaks reported by annual period with exception of the current period to date for 2018 and HIIAT Green in 2016 following introduction of mandatory report (non-Norovirus) from April 2016. Comparative data for this setting within NHSScotland identified no reported incidents or outbreaks outwith NHS Greater Glasgow and Clyde.

Appendix 2: Ward Floor Plan 2A

Appendix 3: Ward Floor Plan 2B

Appendix 4: Health Protection Scotland - Epidemiology Report, December 2018

Royal Hospital for Children, NHS Greater Glasgow & Clyde

Background

Health Protection Scotland (HPS) were asked to support NHS Greater Glasgow and Clyde (NHSGGC) with the ongoing investigation of the potentially contaminated water system at the Royal Hospital for Children (RHC). The RHC opened in June 2015 replacing Yorkhill Hospital (YH). The patient population that was cared for in Schiehallion ward and Ward 7A of Yorkhill Hospital are now cared for in Wards 2A and 2B of RHC. The purpose of this report is to describe the incidence of positive blood cultures in the patient population cared for in these wards and more widely across RHC/YH hospitals, before and after the move to the RHC.

Methods

For the purposes of this report, the patient population was categorised into two groups:

- 2A/2B Group
 - Patients cared for in Yorkhill Hospital (YH) Schiehallion or Ward 7a; Royal Hospital for Children (RHC) Wards 2A and 2B; patients cared for in haematology/oncology specialties including A&E admissions with previous admission to RHC haematology/oncology specialties.
- RHC Other Group:
 - Patients cared for in other specialties in RHC/YC

Case and episode definitions

Data were extracted from the Electronic Communication of Surveillance in Scotland (ECOSS) system. An extract of all positive blood cultures for any patient under 16 years of age in NHSGGC was taken from ECOSS on the 13th June 2018 with an update taken on 20th August 2018. The case definition was a positive blood culture reported in patients aged less than 16 years in RHC/YC between July 2013 and June 2018. An episode was defined as one positive sample per species in a rolling 14-day period.

Microbiology

Positive blood cultures of the following micro-organisms were included:

- Gram-negative bacteria
- Gram-positive bacteria
- *Staphylococcus* species
- Environmental bacteria (all species of the following: *Achromobacter*; *Acinetobacter*; *Aeromonas*; *Brevundimonas*; *Brevibacillus* species; *Brevundimonas*; *Burkholderia*; *Chryseobacterium*; *Citrobacter*; *Cupriavidus*; *Delftia acidovorans*; *Elizabethkingia*; *Enterobacter*; *Klebsiella*; *Pantoea*; *Pseudomonas*; *Rhizobium*; *Rhodococcus*; *Serratia*; *Sphingomonas*; *Stenotrophomonas*).

- Non environmental bacteria (all species of the following: *Abiotrophia*; *Actinomyces*; *Aerococcus*; *Bacillus*; *Bacteroides*; *Bifidobacterium*; *Brevibacterium*; *Capnocytophaga*; *Clavibacter*; *Clostridium*; *Corynebacterium*; *Dermacoccus*; *Dietzia*; *Enhydrobacter*; *Enterococcus*; *Escherichia*; *Fusobacterium*; *Gemella*; *Granulicatella*; *Haemophilus*; *Kingella*; *Kocuria*; *Lactobacillus*; *Lactococcus*; *Leclercia*; *Leuconostoc*; *Microbacterium*; *Micrococcus*; *Moraxella*; *Mycobacterium*; *Neisseria*; *Paenibacillus*; *Propionibacterium*; *Proteus*; *Raoultella*; *Roseomonas*; *Rothia*; *Salmonella*; *Staphylococcus*; *Streptococcus*; *Veillonella*).
- Fungi (all species of the following: *Candida*; *Rhodotorula*).

The following species were previously isolated in water samples from 2A/2B:

Achromobacter; *Acinetobacter*; *Brevundimonas*; *Burkholderia*; *Chryseobacterium*; *Comamonas*; *Cupriavidus*; *Delftia acidovorans*; *Elizabethkingia*; *Pantoea*; *Pseudomonas*; *Rhizobium*; *Sphingomonas*; *Stenotrophomonas*.

The following species were previously isolated in drain samples from 2A/2B: *Citrobacter*; *Cupriavidus*; *Delftia acidovorans*; *Enterobacter*; *Klebsiella*; *Pantoea*; *Pseudomonas*; *Serratia*; *Stenotrophomonas*.

Analytical methods

The total numbers of episodes of positive blood cultures in the included micro-organisms were described and polymicrobial episodes, where more than one species was identified in the blood sample, were compared in the 2A/2B Group with the RHC Other Group. Monthly incidence rates were calculated using bed-days at specialty level as the denominator. These data were obtained from the Information Services Division ISD(S)1 data source. The denominators for the 2A/2B Group were the monthly number of bed-days for haematology/oncology specialties in RHC/YH. The monthly bed-days for all other specialties in RHC/YH were used as the denominators for the RHC Other Group.

The incidence rates between July 2013 and June 2018 were analysed using statistical process control (SPC) U charts.¹ The SPC charts describe the incidence of positive blood cultures over time with the opening of the RHC represented in the charts with a vertical black line. In addition, the following control measures have been added to the 2A/2B chart – filters added to taps marked as an orange vertical line and cleaning of drains marked as purple vertical line.

The incidence rates for Gram-negative bacteria, Gram-positive bacteria, environmental bacteria and fungal blood cultures before and after the move to RHC were calculated and compared using rate ratios. In addition, two SPC charts were created each for Gram-negative, Gram-positive and environmental bacteria positive blood cultures; one for 2A/2B Group and one for the RHC Other Group. The centreline of the SPC was calculated as the median of the monthly rates between July 2013 and June 2018. The following SPC rules were applied:

TABLE 1: Statistical Process Control (SPC) rules

Rule	Description	Marker
Outlier	Data point(s) exceeding the upper or lower control limit (as 3 standard deviations)	Red diamond
Trigger point	Data point(s) exceeding the upper or lower warning limit (as 2 standard deviations)	Yellow triangle
Shift	A run of 8 or more consecutive data points above or below the centreline	Circle drawn round points
Trend	A run of 6 or more consecutive data points either increasing or decreasing.	N/A

The incidence rate of positive blood cultures over the 5-year period and the latest two-year period were compared with the combined incidence rate of the other two Scottish children's hospitals (Royal Aberdeen Children's Hospital (NHS Grampian) and Royal Hospital for Sick Children (NHS Lothian)). These were compared by calculation of rate ratios and accompanying p-values.

Results

Episodes

A total of 1,786 episodes were identified in 1,149 patients in RHC/YH over the five-year period from July 2013 to June 2018. In the 2A/2B Group, there were 542 episodes in 234 patients (range 1 - 23 episodes per patient) with a median age of 4 years. In the RHC Other Group there were 1,244 episodes in 927 patients (range 1 – 17 episodes per patient) with a median age < 1 years. The number of episodes in each patient group is described in TABLE 2. As the episode definition is by species, a patient could have more than one episode at any one time. TABLE 2 also describes the number of polymicrobial episodes when more than one species was identified in blood sample(s). Patients in the 2A/2B group were more likely to have a polymicrobial episode of positive blood culture ($p < 0.001$).

TABLE 2: Total number of episodes (n=1,786) broken into each subgroup of 2A/2B Group and RHC Other Group over 5 years

	2A/2B Group			RHC Other Group		
	Monomicrobial (n = 413) ¹	Polymicrobial (n = 129) ²	Total (n= 542)	Monomicrobial (n = 1,101) ¹	Polymicrobial (n = 143) ²	Total (n=1,244)
Gram-negative bacteria	110 (65%)	59 (35%)	169	193 (85%)	35 (15%)	228
Gram-positive bacteria	291 (82%)	66 (18%)	357	884 (89%)	105 (11%)	989
Staphylococcus species	208 (87%)	30 (13%)	238	643 (94%)	41 (6%)	684
Environmental	77 (61%)	50 (39%)	127	101 (81%)	23 (19%)	124
Non-Environmental	324 (81%)	75 (19%)	399	976 (89%)	117 (11%)	1,093
Fungi	12 (75%)	4 (25%)	16	24 (89%)	3 (11%)	27

¹ Monomicrobial was only one species isolated on the episode reporting date.

² Polymicrobial if more than one species was isolated from cultures of blood samples on the same day as the episode reporting date.

Incidence rates

Figures 1 to 3 describe the incidence rates using SPC charts showing the incidence of positive blood cultures before and after the move to the RHC (23 months of data from YH and 37 months from RHC).

Figure 1 describes the incidence of Gram-negative blood cultures in both patient groups. The incidence of Gram-negative blood cultures in the 2A/2B Group prior to the move and in the months following were below the centreline of the SPC.

From March 2017, there was a run of 10 months/data points above the centreline identifying an upward shift in the rate with one point above the upper warning limit (UWL).

In March and May 2018, the 2A/2B Group had a rate above the upper control limit (UCL) highlighting a higher than expected incidence of positive blood cultures.

No shift in rates was observed in the RHC Other Group however the rate was above the UWL in April 2014, February 2016 and April 2017. In addition, comparison of the overall incidence of Gram-negative blood cultures before and after the move to RHC indicated the rate was higher after the move in the 2A/2B Group (RR = 1.47, CI: 1.05 to 2.04, $p = 0.023$) and did not change in the RHC Other Group (RR = 1.15, CI: 0.87 to 1.52, $p = 0.34$).

FIGURE 1: SPC charts of Gram-negative blood culture incidence rates per 1,000 total occupied days for 2A/2B Group and RHC Other Group.

Figure 2 describes the incidence of Gram-positive blood cultures in both patient groups.

There was an upward shift in incidence of Gram-positive blood cultures in the RHC Other Group prior to the move with rates above the UWL in January 2016 and March 2017 and an outlier (above the UCL) in June 2017.

In 2A/2B Group, there was an upward shift after the move and the rate was above UWL in January 2016, and in April, May and June 2017. *Staphylococcus* species accounted for 52% of the Gram-positive blood culture episodes with 45% of those being *Staphylococcus epidermidis*. In addition, comparison of the overall incidence of Gram-positive blood cultures before and after the move to RHC indicated the rate was higher after in both the 2A/2B Group (RR = 1.43, CI: 1.14 to 1.81, $p = 0.002$) and the RHC Other Group (RR = 1.23, CI: 1.07 to 1.41, $p = 0.003$).

FIGURE 2 SPC charts of Gram-positive blood culture incidence rates per 1,000 total occupied days for 2A/2B Group and RHC Other Group.

The incidence of positive blood culture caused by species of environmental bacteria (described in the methods section) which included all species isolated in water or drain samples taken from 2A/2B are shown in Figure 3.

In the 2A/2B Group, the SPC chart shows a shift below the centreline for 17 months from January 2015 to May 2016, then a shift above the centreline from April 2017 to December 2017. The rate was also above the UCL, and therefore higher than expected, in March and May 2018 and was above the UWL in November 2017 and June 2018.

There were no shifts in the incidence rates in the RHC Other Group, though the incidence was above the UCL in February 2016, April 2017 and July 2017 and above the UWL in February 2017.

In addition, comparison of the overall incidence of environmental bacteria positive blood cultures before and after the move to RHC indicated the rate was marginally higher in both the 2A/2B Group (RR=1.45, CI 0.98 to 2.13, $p=0.06$) and RHC Other Group (RR = 1.52, CI: 1.02 to 2.29, $p=0.04$) however the 2A/2B group the increase was not significant ($p > 0.05$) which may be due to the small sample size.

FIGURE 3: SPC charts of environmental bacteria blood culture incidence rates per 1,000 total occupied days for 2A/2B Group and RHC Other Group.

A comparison of the overall incidence of fungal positive blood cultures before and after the move to RHC indicated the rate did not change after the move in either group (2a2b group RR = 1.65, CI: 0.53 to 5.12, $p = 0.40$; RHC Other group RR = 0.86, CI: 0.40 to 1.89; $p = 0.71$).

Figure 4 describes the environmental bacteria blood culture isolates in both groups. The episodes with dots represent the first and recurrent episodes of the same species in the same patient. There were 20 patients with two episodes, one patient with three episodes and one patient with five episodes.

FIGURE 4: Quarterly episodes of environmental organism blood cultures in 2A/2B group and RCH other group. Dots represent the first and recurrent episodes of the same species from the same patient.

Comparison with other health boards

When comparing the overall rate over 5 years at RCH/YH to the combined rate of the other two Scottish children's hospitals (Royal Aberdeen Children's Hospital (NHS Grampian) and Royal Hospital for Sick Children (NHS Lothian)), the incidence of positive blood cultures in RCH/YH was higher compared with the other hospitals for environmental bacteria (RR = 1.70, CI: 1.34 to 2.16, $p < 0.001$) and fungi (RR = 5.36, CI: 2.12 to 13.53, $p < 0.001$), but lower for Gram-positive bacteria (RR = 0.71, CI: 0.66 to 0.77, $p < 0.001$) and non-environmental bacteria (RR = 0.79, CI: 0.73 to 0.85, $p = 0.001$). There was no difference in the rates of Gram-negative blood cultures (RR = 1.12, CI: 0.95 to 1.33, $p = 0.16$).

When compared over 2 years (July 2016 to June 2018), the rate of positive blood cultures was higher in RCH/YH for environmental bacteria (RR = 2.74, CI: 1.47 to 5.10, $p < 0.001$), Gram-negative bacteria (RR = 1.29, CI: 1.01 to 1.66, $p = 0.038$) and fungi (RR = 12.26, CI: 1.65 to 90.97, $p < 0.001$) and lower for Gram-positive bacteria (RR = 0.81, CI: 0.72 to 0.92, $p = 0.001$), and non-environmental bacteria (RR = 0.79, CI: 0.70 to 0.89, ($p < 0.001$)).

Summary and Recommendations

In summary, the overall incidence of Gram-negative, Gram-positive and environmental bacteria blood cultures increased in the 2A/2B Group after the move to the RHC. The RHC Other Group, the incidence of Gram-negative bacteria and fungal blood culture did not change and the incidence of Gram-positive and environmental bacteria blood cultures increased. SPC charts provide an alternative method of analysis that identifies variation at a level of detail not provided by comparison of incidence rates before and after the move to RHC. The SPC charts indicated that the Gram-negative, Gram-positive and environmental bacteria blood culture incidence rates in the 2A/2B Group were higher than expected following the move to RHC. The same changes in the incidence of blood cultures were not observed in the RHC Other Group. Whilst this conclusion must be interpreted with some degree of caution, as changes in the patient population have not been accounted for in this analysis, the shift in the incidence identified by the SPC charts indicates that the trends in blood culture incidence changed after this time.

Patients in the 2A/2B Group were more likely to have a polymicrobial episode than patients in the RHC other group. This was highest in the patients with a positive blood culture of environmental bacteria where nearly 40% had a polymicrobial blood culture. This is similar to figures reported in the literature with higher risk of polymicrobial bloodstream infection being associated with younger age groups and presence of central venous catheter.³⁶ The rate of environmental bacteria and fungal blood cultures were higher at RHC/YH than the other Scottish paediatric hospitals over 5 years and over the latest 2-year period. In contrast, the incidence of Gram-positive blood cultures, often considered to be associated with devices and device care, was lower in RHC/YH compared with the other Scottish paediatric hospitals.

Ward 2A and 2B have been closed since the 26th September 2018. It is recommended that when the wards re-open that all positive blood cultures are monitored in particular those related to an environmental organism.

Limitations

There are a number of limitations associated with the use of ECOSS blood culture data. All positive blood samples apart from those reported through mandatory surveillance programmes are non-validated records. The cases may include contaminants, and may include non-blood cases which are incorrectly mapped to a blood sample within either the laboratory system or within ECOSS. From the data collected through the enhanced *Staphylococcus aureus* bacteraemia (SAB) surveillance programme, 10% of episodes in under 16s were classed as contaminants² whereas the enhanced *Escherichia coli* bacteraemia (ECB) surveillance the figure was less than 1% (unpublished data).

The cases were identified using only laboratory data without any clinical review of patients. It is not possible to determine whether changes in incidence are confounded by changes in the patient population and their underlying medical conditions. Duplication per species in ECOSS may mean that a patient is recorded as having more than one episode of positive blood culture in a 14-day period leading to an overestimate of the number of episodes. The breakdown of polymicrobial samples only included isolates recorded on the same day as the episode reporting date which may underestimate the numbers of polymicrobial episodes.

In addition, the comparison between RCH/YC and paediatric hospitals in other health boards should also be interpreted with caution. Differences in the patient population between the RHC/YC and the other children's hospitals may introduce bias to the comparison.

A Preliminaries / General Conditions

A1 THE PROJECT GENERALLY

A10 PROJECT PARTICULARS

110.000 THE PROJECT AND BIM REQUIREMENTS:

- Particulars of the project as a whole are
 - Provided within the Main Contract Preliminaries.
 - Building Information Modelling (BIM) requirements
 - Contractor to demonstrate collaborative 3D Level 2 BIM maturity through defined and compliant information and data on the project.
- BIM Execution Plan and Master Information Delivery Plan
 - Provide pre-contract BIM Execution Plan in response to the EIR.
 - Contribute to the pre-contract BIM Execution Plan in response to the EIR.
 - After contract award provide further BIM Execution Plan confirming the supply chain's capabilities and providing a Master Information Delivery Plan (MIDP).
 - After contract award contribute to a further BIM Execution Plan confirming the supply chain's capabilities and providing a Master Information Delivery Plan (MIDP).
- Comply as appropriate with the following codes and standards
 - BS EN ISO 19650-1
 - BS EN ISO 19650-2
 - PD 19650-0 (transition guidance)
 - PAS 1192-3
 - BS 1192-4
 - PAS 1192-5

120.000 THE EMPLOYER:

- NHS Greater Glasgow & Clyde Health Board

130.000 CONTRACT ADMINISTRATOR:

- The term Contract Administrator (CA) is used throughout this specification and their duties will be carried out by
- the Project Manager WGM Consulting Engineers

140.000 DESIGN AND PROJECT TEAM:

- Client Representative - Steve Russell: NHS GGC Capital Planning
- Principal Designer - Stephen Kerr: Wylie Shanks Architects
- M&E Designers – Chris O'Reilly: WGM Consulting Engineers
- Architects – Stephen Kerr: Wylie Shanks Architects
- Quantity Surveyors - Danny McKinney: Storrier & Donaldson
- Structural Engineers - Scott Morrison: David Narro Associates

BS APPENDIX

BS 1192-4:2014

A11 TENDER AND CONTRACT DOCUMENTS/PRELIMINARIES

110.000 THE TENDER DRAWINGS:

- The tender drawings are as per the drawing registers/document issue sheets, issued as part of the contract information

140.000 PRE-CONSTRUCTION INFORMATION:

- Comply with The Construction (Design and Management) Regulations 2015. Preliminaries Section

The Contractor and associated Sub-Contractor for this package of works, will be bound by the Preliminaries, Contract Conditions, Form of Tender etc. pertaining to the Building Services.

No claim will be entertained which may arise from the Contractor's and associated Sub-Contractor's failure to have examined the Conditions of Contract fully, and it will be assumed that any costs arising from same are included within their tender submission.

The Contractor is recommended to visit the site prior to submitting his tender to ascertain all local conditions and restrictions likely to affect the execution of his works. No claims arising from failure to do so will be considered.

Standard Specification

The design and installation will comply with this Performance Specification for the M&E Services, as detailed below and as further detailed within sections A, B, R, S & T and within the associated appendices and tender drawings where relevant.

Design Responsibilities

Reference to the QS's detailed contractor design items, including those noted below, however the list is not exhaustive:

BMS and Automatic Control Systems

KNX Control System(s) for Radiant Panel and ancillary miscellaneous systems

Fire Smoke Damper Systems including controls and interface to existing fire smoke damper systems

Primary/Secondary support and fixing and bracketing systems.

Secondary steelwork supports for main plant items

Builderswork Drawings

Equipment base details.

All holing and general builderswork requirements.

Access requirements.

Installation and Co-Ordinated Drawings

Allow for all necessary contractor designs/design elements, design development and working drawings, including Level 2 BIM co-ordination for all services/service elements and building/structural elements for areas that are heavily serviced including for the following areas:

- Plant Rooms
- Service Risers
- Ductwork and Pipework systems

Allow for the preparation of record information

Allow for the preparation of Operating and Maintenance Manuals and record drawings/information.

General

Dimensioned layout and fabrication drawings.

Fully detailed arrangements of Plant Rooms/Areas, Control Panels, Ductwork and duct mounted ancillaries, dampers, smoke dampers etc.

Detail drawings of power/control systems, primary and secondary co-ordinated support and bracket systems and connections to plant and equipment.

Power, control and miscellaneous systems wiring diagrams.

Drawings showing the work of Specialist Sub-Contractors and Manufacturers.

Manufacturers drawings generally.

The Sub-Contractor will submit drawings as required to suit the construction programme. The drawings will be progressed to a level sufficient to allow full co-ordination with other services and to permit proper installation of the works. The main Contractor will be responsible for making sure the Mechanical, Electrical and Plumbing drawings are fully co-ordinated.

Drawings prepared for each area will be produced to allow a minimum period of 20 working days (4 weeks) for appraisal by the Employer/Contract Administrator, who may wish designs to be amended or require the addition of further detail or clarification of matters. A further 10 working days (two weeks) will be allowed for formal issue of the drawings. Work associated with the corresponding area on site will not commence until each drawing has been submitted for comment and formal acceptance has been given, in accordance with this specification.

The appraisal procedure is considered to be vital to the successful incorporation of the Sub-Contractor's designs, and it is essential that the programme for preparation, appraisal and formal issue of drawings is maintained to allow full consideration prior to the formal issue of construction drawings, by the contractor.

Suitability of M&E/Subcontractors

The selection of the correct M&E contractor will be an integral part of the project and will clearly need to be of a suitable standard and have the necessary skills, credential and track record for carrying out large complex Design and Build projects, with suitable and readily available resources. The M&E Contractor must be acceptable to all of the design team in its entirety, and where any selected M&E Contractor is not found to be acceptable to any one of the design team members, this contractor will be discounted from the project selection process and deemed not suitable for this project.

Copyright

All rights reserved. No part of the drawings, specification, and/or documentation produced by WGM Consulting engineers may be reproduced, stored in any retrieval system or transmitted in any form or by any means, electronic, mechanical, photocopying, recording or otherwise without the prior written permission of the Copyright owner.

A2 THE CONTRACT

Refer to the details/information issued by Storrier & Donaldson along with any supporting supplementary information that may be issued by the employer.

B0 Project Particular Specification

B01 GENERAL REQUIREMENTS

- 1.1 This specification provides the outline project details and scope of works along with the necessary detailed requirements for the alterations to provide fully upgraded Ward 2A Project for the Ventilations and associated services installations to be carried out within the Royal Hospital for Children, Queen Elizabeth University Hospital Campus, Glasgow.
- 1.2 Throughout the project works the existing electrical services shall be altered, extended and renewed in line with Current Codes of Practice (COP), British and European Standards (BS's and BSEN's) along with the Local Authority (LA) requirements. The contractor shall also be and make themselves familiar with all relevant Health Technical Memorandum (HTM), Scottish Health Technical Memorandum (SHTM) and Scottish Health Technical Notes (SHTN), SCART Compliance and HAI Scribe requirements and compliance that are fully applicable to the elements of the project works that are to be carried out, in particular for installation and for commissioning of systems associated with this project.
- 1.3 All sections of the mechanical services installations and works shall be co-ordinated before and during installation with all other trades, for example Mechanical Services Contractors, Plumbing and Public Health Contractors and Building Works Contractors etc. The Contractor shall be held liable for any abortive work carried out due to this procedure not being followed.
- 1.4 All project works and alterations / installations covered under this project shall be programmed and carried out in accordance with the client and principle contractors agreed contract programme, and make all necessary allowances including extended working hours and weekends as required to achieve this.
- 1.5 Our Client expect only the highest possible quality of installation for the entire project and the electrical services, and will not accept anything short of the highest possible standards, any part of the installation that is deemed to be not up to the Clients or engineers expectations and the highest possible standard will have to be rectified and brought up to in line with the highest standard for a quality installation at the contractors own expense.
- 1.6 All project works and installations or alterations covered under this project shall be programmed and carried out in accordance with the Clients agreed contract programme, as the project is within a live hospital environment the contractor must make all necessary allowances for the following:
 - a) Out of hours and weekend working
 - b) Programming shutdown in advance and giving at least 10 days' notice in writing (to NHS Estates Pro-Forma) to the local estates department.
 The contractor must recognise that the works include for areas of works that lie out with the contract works areas, where working access and access times will require to be out with the normal working contract period, and the programming and interface of works to these areas is crucial to the project running smoothly, and being complete on programme.
- 1.7 Our Client GGC NHS expects the highest possible quality of installation for the entire project and the electrical services, and will not accept anything short of the highest possible standards, any part of the installation that is deemed to be not up to the Clients or engineers standard will have to be rectified and brought up to in line with the highest standard for a quality installation at the contractors own expense.
- 1.8 The existing fire alarm systems serving the areas associated with the works shall be altered as required, to allow the new systems components and devices to be incorporated, this shall include for all necessary isolations, taking down and reinstatement as detailed and required and as part of these works, the contractor shall allow for a fully working temporary fire alarm system interfaced to the main Fire alarm system panels, to cover the main corridors and areas of works, along with all

areas that require to be isolated to allow the works to proceed – This particular item is for reference only and will be carried out under the electrical works package.

- 1.9 Contractor liaison and co-ordination of the works with the QEUH Estates team and the occupants of the live building where the works are being carried out shall be the responsibility of the contractor, this needs very careful thought and full co-ordination by the contractor so that all systems can be installed as required and completed, along with commissioned and the necessary QEUH Estates personnel being given sufficient notice and having the opportunity to witness the testing, commissioning of all systems for the project works, as detailed within this specification and detailed on the project layout drawings.

Programming and co-ordination needs to be thought out, prepared and implemented well in advance for all aspects of the project. The principle contractor must appoint a designated project manager to run, programme be responsible for and to co-ordinate and carry these duties out, including services installation co-ordination.

The contractor must provide full site services co-ordination, in terms of installation and programme, either by means of an in house dedicated project engineering manager or by sub-contracting these services out to a specialist co-ordination company, these duties shall include but not be restricted to the following:

- As the principle contractor for the project provide all necessary H&S Information and a suitably prepared Construction Phase Health and Safety Plan, as detailed by the CDMD/Principle Designer
- Full Co-ordination of all Builderswork, Mechanical and Electrical installations, as required for the project, including existing services and systems.
- Provide M&E Co-ordinated services drawings as required, including all builderswork requirements.
- Ensure services are installed in accordance with the specification and drawings, and that all relevant regulations, SHTM's, SCART requirements etc. and are fully adhered to, provide working and installation drawings as required to demonstrate compliance with these items where necessary or where requested by the client and CA.
- Co-ordination with other trades, by way of installation and programme.
- Provide in advance weekly detailed programmes of planned works, so that technical issues can be properly co-ordinated.
- Co-ordination of commissioning of all M&E systems/services as detailed and to ensure programmes are met, witness testing takes place and all systems are properly commissioned and certified prior to the Client taking possession or assuming beneficial use of the systems.

B02 MECHANICAL SERVICES PROJECT PARTICULAR

300.000 GENERAL

300.010 SITE LOCATION:

- Queen Elizabeth University Hospital, 1345 Govan Road, Govan, Glasgow G51 4TF

300.020 DESCRIPTION OF THE SITE:

- Acute Hospital Campus, incorporating adult and children's hospitals and facilities

310.000 DESCRIPTION OF THE WORKS

310.010 GENERAL

The following Mechanical Services Particular Specification details the Project Works in connection with the Upgrade of the existing Hematoma Oncology Teenage Cancer Trust Ward 2A together with other associated works, all within The Royal Hospital for Children, Queen Elizabeth University Hospital, Glasgow.

Ward 2A HOTCT requires to be substantially upgraded to fully meet the client's present requirements, hence the associated works proposed for this area include the significant replacement and modification of the existing M&E Services and the Building Fabric, such that the main Bedroom Suites and associated main accommodation areas can be effectively positively pressurised with Central Station HEPA filtered air and an appropriate Pressure Cascade system adopted, which includes a Ward Isolation Facility (Transfer Lobby located at the end of Ward 2A, where the HOTCT Corridor connects to the general Hospital Street). Air infiltration to the positively pressurised accommodation areas will be significantly reduced resulting in a reduction in both the infection and cross contamination risks, to the extent where they can be managed more effectively. The Ward 2A Hematoma Oncology/Teenage Cancer Trust area will be served by a new duplicate Supply and Extract Air Handling Unit Facility with duplicate En-suite/Toilet Extract Ventilation Plant, providing a N+1 facility for the Ward.

Works in connection with Ward 2A Bone Marrow Transplant will be far less extensive as it has relatively recently undergone some partial refurbishment in connection with its existing facilities to generally improve infection control issues, however whilst a substantial upgrade of this ward is not being considered at present, other measures relating to the improvement in the general quality of the air supplied to the area will be implemented to reduce general infection risks and risks associated with cross contamination between the Exhaust and Supply air streams within the existing associated Air Handling Unit. A Ward Isolation Facility will also be provided (Transfer Lobby located at the end of Ward 2A), where the BMT Corridor connects to the general Hospital Street. Other works proposed within the Ward 2A BMT area comprise of less extensive general refurbishment works in connection with the MIBG Suite together with more significant new works in connection with the NPVL SCH 010 Suite which involves amending the existing ventilation strategy, although as this work is yet to be fully determined it is covered by a provisional sum allowance at this stage. The NPVL facility will be designed to cater for Immuno-compromised patients that have also contracted diseases such as Measles or Chicken pox.

Works in association with Ward 2B Day Ward are less significant as these works are generally only limited to works in connection with improving the quality of air supplied to the area, to reduce infection risks and risks associated with cross contamination between the Exhaust and the Supply Air Streams within the Air Handling Unit.

This contract also includes for the strip out and safe removal of existing identified redundant plant and equipment. Some equipment will be identified as equipment to be carefully dismantled and laid aside for future use (which may be on this Contract or on some other Contract determined by the Client, in the future), or otherwise require to be removed from the site and safely disposed of. The Tender Drawings indicate what Plant and Equipment is to be stripped out and safely and responsibly removed from site,

and which Plant and Equipment is to be retained for use on this project, or laid aside, for the client's future use. Should there be any ambiguity regarding this matter, as to what is to be removed from site and what is to be retained on site, clarification should be sought from the Contract Administrator, at an early date.

It should be noted that the Existing Hematoma Oncology/TCT & BMT Ward 2A will be shut down entirely for the duration of the Construction Works, to carry out all major works and more minor works (Remedial Works in Connection with Ward 2A BMT Existing AHU) in this area, although it should be noted that it is expected that the Remedial Construction Works in connection with Ward 2B Day Ward will be carried out within a time period of no more than two weeks, meaning that the associated Ward 2B Day Ward will only be shut down for approximately 4 weeks (allowing for decanting and Validation processes), or as short a period of time as is feasibly possible to limit the down time for Ward 2B Day Ward. These Remedial Works briefly comprise of the removal of the existing Thermal Wheel and the Installation of new F9 and HEPA terminal AHU filters and the upgrading of the corresponding Fan/Motor/Inverter Units, together with other associated works (Controls, C&P Wiring, etc), and general making good.

Prior to the progress of the Remedial Works in connection with the existing Ward 2A BMT and Ward 2B Day Ward AHUs Commissioning Works will be carried on the associated main ventilation systems to verify the existing Air Flow rates on all the main branch ducts serving the corresponding AHUs, together with a check on the main AHU system air flow rates and corresponding duct static pressures. The Contractor will be responsible for liaising with the local NHS Estates Department and the CA regarding the timing of these works to ensure they are carried out strictly in accordance with formal pre-arranged agreements. Prior to the progress of the Remedial Works all necessary temporary system isolations will be arranged and otherwise agreed with the Local NHS Estates Department in conjunction with the CA, well in advance of the required implementation of these Works. Should any additional problem issues be discovered with the existing equipment or systems during the course of the works, or prior to the Works, these issues must be reported immediately to the Contract Administrator and the Local NHS Estates Department, for further consideration and instruction on any appropriate remedial action, where this may be required.

In addition to the installation of new Supply and Extract AHUs and corresponding Ventilation Ductwork distribution systems, the Works will also include for the installation of new LTHW Heating and Chilled Water Pipework distribution systems which generally extends from new flow and return branch connections made into the corresponding existing mains pipework at 4th floor level. New Run-Around-Coil type Heat Recovery systems will be provided for each of the new Ward 2A HOTCT AHUs. The existing Domestic Water Services pipework systems will be modified and re-routed as required to accommodate the new Ventilation ductwork running down the main Ward Corridor areas. New Domestic Cold Water supplies will be provided for the Heat Recovery systems located within the new 4th Floor Ventilation Plant Room. The Existing Sprinkler Services system will be extended to cover the new 4th floor Plant Room area and otherwise modified on the 2nd and 3rd floor areas (Bed Store) to cater for all aspects of the Refurbishment Works. Further modifications will be made to the existing Drainage, Rainwater, Medical Gas and Pneumatic Tube Systems as required to cater for the Refurbishment Works, all as generally detailed on the Tender drawings. Thermal Insulation must be applied to all new and modified Ductwork and Pipework distribution systems where particularly required to meet the general requirements of the specification.

A new autonomous BMS will be provided to fully meet the requirements of the Hematoma Oncology Teenage Cancer Trust area powered from a separate Essential Services Power Supply. The new Ward 2A BMS will however be interfaced with the existing Building Wide WAN Controls system such that remote alarm, monitoring and other services can be utilised from other remote Head End facilities within the building. All new Mechanical services Plant and equipment installed to serve Ward 2A HOTCT area that requires either Power or Controls facilities will be wired from the new Ward 2A Mechanical Services Control Panel(s). All power supplies to the new Mechanical Service Control Panels will be provided from an Essential Services Power Supply by the main Electrical Services Contractor.

Modification and general upgrading works will also require to be carried out to the existing Power and BMS Controls serving the Existing Ward 2A BMT and Ward 2B Day Ward AHUs in that uprated Power Supplies and Inverter Drive units will be required for each of the corresponding AHUs (where the

Fans/Motors will be updated). The existing Power and Controls provision associated with the existing Thermal Wheel Units will be removed, new Power and Controls facilities associated with the new terminal AHU F9 and HEPA Filters will be installed, fed from the existing Mechanical Services Control Panels where practicable.

The Contract works will also include for the balancing of the entire new and affected existing elements of the various Supply and Extract Mechanical Ventilation Systems serving Ward 2A HOTCT, Ward 2A BMT and Ward 2B Day Ward including all necessary adjustments to the branch and main duct system Air Flow Volumes, to achieve the necessary Pressure Cascade regime and otherwise to meet the target Ventilation figures agreed following the previous Ventilation Commissioning checks.

Further reference should be made to the Design Logic Tender Drawing (DL)01 for details of the relevant target room pressures. As part of the Commissioning philosophy it is the intention for the ventilation rates to be reduced to approximately that of the minimum level required to meet the basic operating parameters of the associated systems, such that it can be increased slightly at a later date, to possibly cater for conditions including increased pressure drops across the HEPA filters, etc. The minimum ventilation rates should not drop to a level where the basic Heating and Cooling Loads of the various internal spaces cannot be met.

Allowances should also be made for sterile cleaning of the new Supply and Extract/Exhaust Ventilation Ductwork distribution systems that serve the GMP Suite.

All new and existing modified Mechanical Services and associated systems will be fully tested, commissioned and set to work, ready for client inspection and Validation as appropriate, at practical completion stage of the Construction Works.

All appropriate issues in connection with HAI SCRIBE are expected to be fully addressed by the Contractor as part of these works, and appropriate procedures will be agreed prior to the commencement of any works on site, to ensure that infection risks to adjacent hospital areas are controlled, such that they do not present any associated problem issues for the client, during the course of the Construction Works.

The Project will be progressed and otherwise phased in such a manner that will minimise disruption for the client and meet the specific Programme requirements of the Project. It is envisaged that some noisy and/or disruptive work in connection with the Construction Works will have to be carried out either outwith normal working hours, or at specific times, to suit client operations.

During the course of the main element of the Contract Works, when Ward 2A will effectively be closed and made non-operational, normal hours working should be assumed, although it should be noted that where there are specific client concerns with the nature of the works affecting normal operations in other parts of the building, this may be altered to suit their specific requirements. It should be assumed that all main M&E Services isolations and connections to existing M&E services will be progressed outwith normal working hours and in a manner that will limit the disruption to any other services and operations within the building. The Contractor will fully agree the timings of all M&E Services Isolations in writing, in advance of the work being carried out, with the local NHS Estates Department in conjunction with the Client appointed Contract Administrator.

Reference should be made to the Tender drawings and other sections of the Specification for further details of all Mechanical Services systems.

Contract Works Support Documentation

The complete installation covered by this Contract will conform to the requirements of:

- Good Engineering Standards in accordance with the CIBSE Guides and Codes of Practice.
- The Regulations of the Gas, Electricity, Water and Fire Authorities
- The Building Standards (Scotland) Regulations 2014, with latest amendments.
- Home Office Regulations for Public Buildings
- Latest relevant British Standard Specifications and Codes of Practice
- Health & Safety at Work Act 1974
- The Factories Act
- The rules of the FOC for firefighting provision
- Statutory obligations and regulations of all Local Authority, Public Service or Statutory undertaking relating to the execution of the works
- CDM Regulations
- Health Technical Memorandums (HTMs)
- Scottish Health Technical Memorandums (SHTMs)
- Scottish Health Technical Notes (SHTNs)

310.020 SCOPE OF WORKS

The works described within this specification include the following Mechanical Services Installations and Associated Works for the Contract:

- Isolation, disconnection and removal of existing M&E Services plant and equipment, where indicated on Tender drawings.
- Installation of new Supply and Extract Ventilation Plant and Equipment, including AHUs, Terminal Heater Batteries, Grilles, VC Dampers, Shut-off Dampers, Attenuators, External Louvres, Pressure Stabilisers, Smoke/Fire Dampers, etc.
- Mechanical Ventilation Ductwork (including connections to existing).
- LTHW Heating Pipework (including connections to existing and new Heat Recovery Pipework Systems) serving new Air Handling Units (including modifications and temporary isolations to existing LTHW Heating systems).
- Chilled Water Pipework Systems (including connection to existing) serving new AHU (including modifications and temporary isolations to existing Chilled Water system).
- Above Ground Soil Waste Drainage Systems (minor works as detailed on Tender Drawings).

- Domestic Water Services Systems (minor works as detailed on Tender Drawings).
- Specialist Medical Gas Services (minor works as detailed on Tender Drawings).
- Rainwater Services Systems (minor works as detailed on Tender Drawings)
- Pneumatic Tube System (minor works as detailed on the Tender Drawings)
- Sprinkler Services (new works and modifications to Existing Installation).
- Pressure Monitoring System (including provision of new Data Logger Unit for Temp, Pressure, Humidity, Press Difference, etc)
- Electrical Power Supplies to Mechanical Services Plant and Equipment (from Mechanical Services Control Panels). Power supplies to C/Ps by Electrical Contractor/
- Thermal Insulation
- BMS/Controls Systems (including modifications to existing)
- Comprehensive Testing and Commissioning of all M&E Services Systems and associated Equipment, to include pre-testing/commissioning of Existing Ventilation, LTHW Heating and Chilled Water systems
- Setting various Mechanical Services Systems to Work, in full preparation for Client's Validation Process.
- The supply of staged technical information to assist with DQ/IQ and OQ submissions by the Specialist Clean Room Contractor.
- The supply of comprehensive Operating & Maintenance Manuals and Record Drawings.

310.030 DESIGN CRITERIA

The environmental design parameters selected for the building interior should meet the general requirements of the following undernoted NHS Specifications to help ensure good comfortable conditions are provided for the building occupants:

- SHTM 03-01 Part A
- SHPN 04 Supplement 1
- SHPN04-01

a) Thermal

Reference has been made to the definition of thermal comfort as mentioned within ISO 7730 1984 and the CIBSE Guide however the following design parameters have been selected as meeting the Client's User Requirement Specifications:

EXTERNAL

Winter	-10°C dry bulb, saturated
Summer	28°C dry bulb; 19°C wet bulb

INTERNAL

<u>Area</u>	<u>Resultant Temperatures</u>
Bedroom	23°C +/- 2°C
Bedroom (TCT)	23°C +/- 2°C
Contingency Area	23°C +/- 2°C
Play/Dining	23°C +/- 2°C
Bedroom En-Suite	24°C +/- 2°C
Bedroom En-Suite (TCT)	24°C +/- 2°C
Staff/Disabled WC	23°C +/- 3°C
Clean Utility/Corridor Drug Bay	23°C +/- 3°C
Ward Corridor	23°C +/- 3°C
TCT Corridor	23°C +/- 3°C
Staff Base	23°C +/- 2°C

Note:

It should be noted that the above room temperatures are essentially normal target values however the room temperatures will be allowed to float closer to the extremes of the range of 18°C to 28°C in exceptional circumstances, when the external winter and summer temperatures are close to the minimum and maximum design values as advised within above. Temperatures within the Corridor areas may also be subject to some variance when there is a requirement for setting various Bedroom temperatures at temperatures well adrift of the normal average room set point temperature value, however it is not expected that the temperatures within the Corridor will fall outwith the allowable range of the float temperatures as mention above and as otherwise defined within SHTM 03-01.

b) Air Quality

Air re-circulation is not an option with this particular Ventilation System due to H&S Issues and client concerns regarding cross infection within the various spaces concerned, therefore it will be avoided, however appropriate heat recovery devices will be incorporated into the design (Run-around-Coils). Due regard will be given to the quality of the air and the amount of CO₂ and microscopic dust in the air, which is supplied to the various rooms. Three stage filtration will be provided including M5, F9 and H12/H13 HEPA filtration, which will be incorporated within the Duty and Standby Central Station Air Handling Units serving the various designated areas as specifically identified elsewhere within the Particular Specification.

Fresh air will be provided at a rate of significantly more than the normal minimum level of 10 litres per second per person to comply with the client's specific requirements for the Ward and meet the corresponding Heating and Cooling loads, however Fresh Air ventilation rates will also be sufficient to ensure the undernoted room pressures are maintained to comply with the User's Requirements and SHTM 03-01 Specifications:

Area	Air Change Rate	Room Pressure
Bedroom	> 10 A/C per hour	10 Pa
Bedroom (TCT)	> 10 A/C per hour	20 Pa
Contingency Area	> 10 A/C per hour	10 Pa
Play/Dining	> 10 A/C per hour	10 Pa
Bedroom En-Suite	> 5 A/C per hour	5 Pa
Bedroom En-suite (TCT)	> 5 A/C per hour	15 Pa
Staff/Disabled WC	> 5 A/C per hour	5 Pa
Clean Utility/Drug Bay	> 10 A/C per hour	5 Pa
Ward Corridor	> 10 A/C per hour	0 Pa
TCT Corridor	> 10 A/C per hour	10 Pa

Due regard will be provided to minimise the possibility of draft discomfort.

c) Noise Levels

Consideration has been given in the design to control the following:-

- Noise from mechanical services plant items into the Building
- Egress of noise from plant items within the building to external sources
- Ingress of noise from external sources
- Other general M&E noise sources

The following criteria are listed as meeting the client's requirements:-

Area	Room Noise Rating
Bedroom	NR 30
Bedroom (TCT)	NR 30
Contingency Area	NR 35
Play/Dining	NR 35
Bedroom En-Suite	NR 30
Bedroom En-Suite (TCT)	NR 30
Staff Disabled WC	NR 35
Clean Utility/Drug Bay	NR 35
Ward Corridor	NR 35
TCT Corridor	NR 35
Plan Room	NR 50

These criteria will be measured at 1.5m above finished floor level.

Noise breakout from the building will not exceed a level which would cause annoyance to prevent quiet enjoyment within neighbouring premises.

d) Vibration

All plant and services will be fitted with effective vibration insulation measures, including anti-vibration mounts, pipework insulation, resilient penetrations, and flexible connections, all as necessary to ensure that services equipment does not cause perceptible levels of vibration in the building structure.

320.000 HEATING AND COOLING

320.010 GENERAL

Works in connection with the LTHW Heating and Chilled Water Systems are all as generally detailed on the relevant Tender drawings and otherwise as described within the specification and other documentation forming part of the Tender package.

320.020 SCOPE OF WORKS

The scope of Works in connection with the LTHW Heating and Chilled Water Systems includes the following:

1. Inspection of all associated existing LTHW Heating and Chilled Water systems that are considered to form part of the Works.
2. The verification of all existing Heating and Chilled Water system equipment and associated services that must be removed or temporarily laid aside for future use, as part of these works, or for the client to use on some other project.
3. The verification and recording of the various present LTHW Heating and Chilled Water Circuit water flow rates for all main existing associated LTHW Heating and Chilled Water systems that are to be removed (main branches only) and those where it is envisaged that the branch connections to the mains are to be made (main branches and associated main Pumped line circuit), prior to the commencement of any disruptive works in connection with the existing LTHW Heating and Chilled Water systems.
4. The strip out and removal of all existing redundant LTHW Heating and Chilled Water systems and equipment as generally detailed on the Tender drawings together with identified Active Chilled Beams, Radiant Panels and associated supports, etc.
5. The temporary or permanent isolations of all associated existing LTHW Heating and Chilled Water systems to ensure they can be set back to work promptly to meet the client's operational requirements for other areas that are served from common. The branch connections into the corresponding LTHW Heating and Chilled Water mains will necessitate the requirement for pre-fabricated pipework assemblies to ensure the associated LTHW and Chilled Water mains down time is reduced to an absolute minimum, and in the order of 8 hours.
6. The installation of new LTHW Heating, Chilled Water and Run-Around Coil Heat Recovery circuits as generally detailed on the Tender drawings and as required to meet the specification, including LTHW Heating and Chilled Water Services Pipework distribution systems, Commissioning Valves, Isolating Valves, Strainers, Venting/Draining devices, Expansion Bellows, Pressure Gauges, Temperature Gauges, Pumps (Heat Recovery System only), Pressurisation Units & Expansion Vessels (Heat Recovery System only), Check Valves, etc, together with all necessary supports. It is not envisaged at this stage that any work will be required to the existing main LTHW Heating Pumps and the main Chilled Water Pumps located within the 4th Floor Plant Room, however a Provisional Sum allowance will be made for this eventuality, should the commissioning results highlight any significant issues. It should be noted that the existing main LTHW Heating and Chilled Water Pump sets are arranged as Duty and Standby, meaning that potential work such as the upsizing of impellers and/or motors is less likely to be problematic from a system shut-down perspective.
7. The Flushing and Chemical Treatment of all LTHW Heating, Chilled Water and Heat Recovery Systems forming part of the Works, including the provision of all necessary additives including Glycol (where specifically specified) to match the existing systems. All external surfaces of LTHW Heating Pipework systems and associated equipment must also be appropriately painted and kept visibly clean and free from dust and general debris throughout the course of the works.
8. The Testing, Balancing and Setting to Work of all new and existing LTHW Heating and Chilled Water Services systems forming part of the Works.

320.030 SYSTEM DESCRIPTION

Within the Ward 2A Hematoma Oncology Teenage Cancer Trust area, it is proposed to remove all redundant existing LTHW Heating and Chilled Water Services pipework distribution systems together with all associated Radiant Heating Panels and Ceiling Mounted Active Chilled Beams, valves, etc., and blank-off these circuits accordingly at their corresponding risers. The existing Radiant Heating Panels located within the En-Suite and Toilet areas, will however be stripped out and laid aside for refitting at a later stage in the Construction Works when the existing ceiling is replaced by a plasterboard ceiling (using new ceiling trims). The removal of the existing services includes all Chilled Water distribution pipework within the Ward 2A HOTCT area together with the Constant and Variable Temperature LTHW Heating circuits. The existing Constant Temperature LTHW Heating circuit presently serves a few Air Heater Batteries and the Existing Variable Temperature LTHW Heating circuit appears to serve both the existing Active Chilled Beams and the Radiant Heating Panels (all mounted on the ceilings). The Chilled Water circuit only appears to serve the Active Chilled Beams.

As part of the present works, it is proposed to run a new Chilled Water F&R circuit from the main existing 4th Floor Plantroom to the new proposed 4th Floor Plantroom with flow and return branches cut into an appropriate section of the existing Primary Chilled Water Circuit, in a way that any associated down time is reduced to an absolute minimum. This will require the off-site fabrication of suitable valved branch connection pieces, which may be readily connected to say an existing flanged connection piece, all designed to effectively minimise the down time of the main Chilled Water Circuit to a maximum of 8 hours. Similarly, it is proposed to cut in new flow and return branches into the existing Constant Temperature LTHW Heating circuit to serve the new proposed Ward 2A HOTCT Air Handling Units together with the various proposed new Re-heater Batteries mounted within the Ward 2A HOTCT Corridor ceiling void, that serve the associated Bedroom Suites and the other main accommodation areas within Ward 2A Hematoma Oncology Teenage Cancer Trust area. As part of the new Ward 2A HOTCT Duty/Standby Air Handling Unit installation, separate Run-Around-Coil Heat Recovery systems will be provided which will be designed to recover a significant amount of heat or coolth from the corresponding Exhaust Air Streams.

Prior to the commencement of any disruptive works in connection with the LTHW Heating and Chilled Water Systems, Commissioning verification works will be carried out to confirm the existing water flow rates of the corresponding Systems. This work should generally be restricted to work in connection with the main flow circuits and main branch circuits, such that the main existing LTHW Heating and Chilled Water Circuits can be re-commissioned to provide the required flow rate for the new circuits whilst still maintaining the existing flow rates to all the various associated main branch circuits, which would be carried out as a second phase of the Commissioning Works. It is envisaged that there will be sufficient flow capability on the existing main LTHW Heating and Chilled Water Services Pumps to cater for the slightly increased loads, however should this not prove to be the case, then the corresponding Pumps will be upgraded to suit including possibly an Impellor and/or Motor upgrade. It should be noted that both the main LTHW Heating Pump set and the main Chilled Water Pump set serving the side of the Building we are concerned with are Duplicate Pump sets, therefore it should not prove to be hugely problematic to upgrade each pump together with associated Inverter Units and Power Supply only if it proves to be absolutely necessary. Following all appropriate Testing, Flushing and Commissioning works including the addition of all necessary system corrosion inhibitors and additives, the LTHW Heating and Chilled Water Systems will be set to work, ready for final validation.

Work in connection with the local pipework system isolations will be carried out outwith normal working hours, and in a way that any associated down time is kept to an absolute minimum (no more than 8 hours on any one Heating/Chilled Water pipework system, and 2 hours on an electrical board that may serve other areas) and will be otherwise arranged to ensure the LTHW Heating and Chilled Water supplies to other areas not forming part of the Refurbishment Works are thereafter maintained to allow proper operation of their associated Heating and Cooling equipment. Additional Isolating and Commissioning Valves will be installed where necessary on the LTHW Heating and Chilled Water branch pipework to ensure this condition can be met. Where new pipework systems are installed as generally indicated on

the Tender drawings, it should be noted that new Isolating, Commissioning, Control, Drain, etc Valves and AAVs will be fitted where indicated. The new LTHW Heating and Chilled Water Services pipework will be of a similar type to the existing and otherwise suitable for the associated operating pressures and temperatures.

Following appropriate pipework pressure testing (to at least 1.5 times the maximum system working pressure) and heat testing, the pipework will be thermally insulated to generally match the existing and otherwise meet the requirements of the Specification. The Thermal Insulation on the Chilled Water Pipework will also be vapour sealed. All LTHW Heating and Chilled Water pipework, Valves, etc will be covered with aluminium cladding within Plant room areas and generally accessible areas, to provide suitable protection. Valves and other line fittings will be covered with appropriate readily accessible insulated valve boxes or proprietary insulated valve bags. All new LTHW Heating and Chilled Water pipework systems and line fittings will be provided with appropriate means of identification and labelling respectively, to generally match the existing.

Supports for Chilled Water pipework systems will not be fixed such that they are in direct contact with the pipework; insulator block will be installed to maintain the efficiency of the corresponding vapour barriers. Drain valves will be fitted at all low points in the LTHW Heating and Chilled Water Systems to ensure the system can be fully drained. Automatic Air vents will be installed at all high points (and at Air Heating/Cooling Coils) in the LTHW Heating and Chilled Water systems to allow appropriate venting.

320.040 VALVES, STRAINERS, TEMPERATURE GAUGES, PRESSURE GAUGES, ETC

Valves, strainers, flexible connections, temperature gauges, pressure gauges etc., will be provided where shown on the Tender Issue Drawings and where otherwise required to meet the requirements of the specification. The types to be used are specified elsewhere within the specification. In addition, drain cocks and air vents will be provided where required at all low points and at all high points in the LTHW Heating and Chilled Water systems, to fully drain and vent the pipework systems respectively.

320.050 PRESSURISATION UNITS (HEAT RECOVERY SYSTEMS)

Two LTHW Fully Packaged Pressurisation Units will be required for the Run-Around-Coil Heat Recovery systems supplied with the new Duty and Standby Air Handling Units serving Ward 2A HOTCT area, which are located within the new 4th Floor Plant Room.

The Heat Recovery system pressurisation units will be suitable for a maximum safe working pressure of up to approximately 3.0 bar(g) with system flow and return temperatures of approximately 15°C and 6°C respectively. The cold fill pressures will set at approximately 1.2 bar(g) and the Heat Recovery System water volumes will each be approximately 200 litres. The pressurisation units will be provided with the following (in addition to other items deemed necessary by the manufacturer): duty/standby pumps, expansion vessel, pressure transducer, high and low system cut outs, mains water break tank, pump run/tripped and hand/off/auto indicators, BMS serial communications part, volt free signal relay (8 No), pump duty sharing and pulsing facilities, compact wall mounted cabinet, high and low water protection devices (within break tank) etc. The pressurisation units will be manufactured by Aquatech, Model 2ET M45-C1-E supplied with a type 30V expansion vessel. The pressurisation units will be suitable for a 230V/1 Phase/50Hz electrical supply. The Contractor will allow for the fitting of appropriate overflow pipes to be taken to the nearest floor gulley or trapped SWP, for safe discharge.

330.000 COLD WATER

330.010 GENERAL

Works in connection with the Domestic Cold Water Systems are all as generally detailed on the relevant Tender drawings and otherwise as described within the specification and other documentation forming part of the Tender package.

330.020 SCOPE OF WORKS

The scope of Works in connection with the Domestic Cold Water Services includes the following items in addition to other general Works specified elsewhere:

- 1 Inspection of all associated existing Domestic Cold Water Services systems that may form part of the Works.
- 2 The verification of all Domestic Cold Water Services pipework distribution systems and associated services that must be removed or temporarily laid aside for future use, as part of these works or for the client to use on some other project.
- 3 The verification and recording of existing water flow rates at any commissioning devices on the existing Domestic Cold Water Services systems, prior to the commencement of any disruptive works in connection with the existing associated Domestic Cold Water Services.
- 4 The strip out and removal of all existing redundant Domestic Cold Water Services systems and equipment as generally detailed on the Tender drawings together with all associated supports, etc.
- 5 The temporary or permanent isolations of all associated existing Domestic Cold Water Services systems to ensure they can be set back to work promptly to meet the client's operational requirements for other areas that are served from common Domestic Cold Water Services systems.
- 6 The installation of new Domestic Cold Water Services systems as generally detailed on the Tender drawings and as required to meet the specification, including Domestic Cold Water Services pipework distribution systems, Isolating Valves, Regulating Valves, Non-return Valves, etc together with all necessary supports.
- 7 The Flushing out, Chemical Treatment and final refilling of the Domestic Cold Waters Services system in accordance with SHTM procedures to fully satisfy the requirements of the local NHS Estates Department.
- 8 The Commissioning/Balancing and setting to Work of the new and adjacent existing Domestic Cold Water Services systems forming part of the Works.

330.030 SYSTEM DESCRIPTION

It is proposed that the main existing Domestic Cold Water Services runs within the Ward 2A Hematoma Oncology Teenage Cancer Trust area will be extensively removed and thereafter replaced with new relocated mains to primarily suit the new Ventilation Ductwork distribution runs proposed for the main Ward Corridor areas. Significant adjoining branch pipework serving the Bedroom and other adjacent areas will also have to be renewed to suit, including the provision of new associated branch isolating/regulating valves. The various new branch connections will thereafter connect to the existing branch connections within the ceiling voids of the Bedroom Suite, etc areas, as generally indicated on the relevant Tender drawings. We do not foresee any significant requirement to alter the existing Domestic Cold Water Services within the Ward 2A Bone Marrow Transplant area, however some relatively minor alterations may be required to the Domestic Cold Water Services systems in connection with the NPVL and MIBG areas, which are covered by Provisional Sums at this stage. It is not anticipated that there will be any requirement to alter the existing Domestic Cold Water Services systems in connection with the Ward 2B Day Ward area.

A new Domestic Cold water Supply will be required to serve the new proposed 4th Floor Plant Room, and in particular the two Run-Around-Coil Heat Recovery systems.

Appropriate allowances will be made for initially isolating and draining down the existing Domestic Cold Water Services system, such that it will not interfere with the general Domestic Cold Water Services provision to other existing adjacent areas, served by the same system. On completion of the present Contract Works the new Domestic Cold Water Services system will be pressure tested, flushed and treated in accordance with the SHTM requirements to meet the requirements of the specification and local NHS Estates Department, and thereafter ultimately 'set to work'.

The existing and new proposed Domestic Cold Water Services systems are both of the Stainless Steel Press fit type as specifically detailed elsewhere within the specification. The various new and modified Domestic Cold Water Services pipework distribution systems will be installed fully in accordance with the requirements of the specification and to otherwise meet the operational requirements of the local NHS Estates Department, although some distribution pipework may require to be re-routed to accommodate the new proposed Ventilation Ductwork runs. A new branch connection will be required from the existing Boosted Domestic Cold Water Supply to serve the new Heat Recovery Systems incorporated within the new proposed Duty/Standby Supply and Extract Air Handling Units located within the new 4th Floor Plant room serving the refurbished Ward 2A HOTCT area, which will connect to the Heat Recovery systems via a common Pressurisation Unit incorporating a Water Board approved break tank.

The existing and new proposed Domestic Cold Water Services systems are both of the Stainless Steel Press fit type as specifically detailed elsewhere within the specification. The various new and modified Domestic Cold Water Services pipework distribution systems will be installed fully in accordance with the requirements of the specification and to otherwise meet the operational requirements of the local NHS Estates Department, although some distribution pipework may require to be re-routed to accommodate the new proposed Ventilation Ductwork runs. A new branch connection will be required from the existing Boosted Domestic Cold Water Supply to serve the new Heat Recovery Systems incorporated within the new proposed Duty/Standby Supply and Extract Air Handling Units located within the new 4th Floor Plant room serving the refurbished Ward 2A HOTCT area, which will connect to the Heat Recovery systems via a common Pressurisation Unit incorporating a Water Board approved break tank.

335.000 HOT WATER

335.010 GENERAL

Works in connection with the Domestic Hot Water Systems are all as generally detailed on the relevant Tender drawings and otherwise as described within the specification and other documentation forming part of the Tender package.

335.020 SCOPE OF WORKS

The scope of Works in connection with the Domestic Hot Water Services includes the following items in addition to other general Works specified elsewhere:

- 1 Inspection of all associated existing Domestic Hot Water Services systems that may form part of the Works.
- 2 The verification of all Domestic Hot Water Services pipework distribution systems and associated services that must be removed or temporarily laid aside for future use, as part of these works or for the client to use on some other project.
- 3 The verification and recording of existing water flow rates at any commissioning devices on the existing Domestic Hot Water Services systems, prior to the commencement of any disruptive works in connection with the existing associated Domestic Cold Water Services.

- 4 The strip out and removal of all existing redundant Domestic Hot Water Services systems and equipment as generally detailed on the Tender drawings together with all associated supports, etc.
- 5 The temporary or permanent isolations of all associated existing Domestic Hot Water Services systems to ensure they can be set back to work promptly to meet the client's operational requirements for other areas that are served from common Domestic Hot Water Services systems.
- 6 The installation of new Domestic Hot Water Services systems as generally detailed on the Tender drawings and as required to meet the specification, including Domestic Hot Water Services pipework distribution systems, Isolating Valves, Regulating Valves, Non-return Valves, etc together with all necessary supports.
- 7 The Flushing out, Chemical Treatment and final refilling of the Domestic Hot Water Services system in accordance with SHTM procedures to fully satisfy the requirements of the local NHS Estates Department.
- 8 The Commissioning/Balancing and setting to Work of the new and adjacent existing Domestic Hot Water Services systems forming part of the Works.

335.030 SYSTEM DESCRIPTION

It is proposed that the main existing Domestic Hot Water Services runs within the Ward 2A Hematoma Oncology Teenage Cancer Trust area will be extensively removed and thereafter replaced with new relocated mains to primarily suit the new Ventilation Ductwork distribution runs proposed for the main Ward Corridor areas. Significant adjoining branch pipework serving the Bedroom and other adjacent areas will also have to be renewed to suit, including the provision of new associated branch isolating/regulating valves. The various new branch connections will thereafter connect to the existing branch connections within the ceiling voids of the Bedroom Suite, etc areas, as generally indicated on the relevant Tender drawings. We do not foresee any significant requirement for altering the existing Domestic Hot Water Services within the Ward 2A Bone Marrow Transplant area, however some relatively minor alterations may be required in connection with works in connection with the NPVL and MIBG areas, which are covered by Provisional Sums at this stage. It is not anticipated that there will be any requirement to alter the existing Domestic Hot Water Services systems in connection with the Ward 2B Day Ward area.

Appropriate allowances will be made for isolating and draining down the existing Domestic Hot Water Services system, such that it will not interfere with the general Domestic Hot Water Services provision to other existing adjacent areas, served by the same system. On completion of the present Contract Works the new Domestic Hot Water Services system will be pressure tested, flushed and treated in accordance with the SHTM requirements to meet the requirements of the specification and local NHS Estates Department, and thereafter ultimately 'set to work'.

340.010 DOMESTIC WATER SERVICES PIPEWORK SPECIFICATION AND STERILISATION PROCEDURES.

Generally all water service pipework shall be carried using Gerberit – Mapress Stainless Steel Pressfitting System in accordance with BSEN-10312 Table 2 and DVGW541 Table 3, DVGW-W270+534, all stainless steel pipework shall be Seamless and shall have a minimum wall thickness of 1.0mm (316 grade).

All pipework systems and components must be stainless steel and WRAS approved, including for the Kemper automatic secondary return/regulating valves – these shall be from their SST range,

The complete water service pipework & associated plant shall be thoroughly and fully sterilised in accordance with BSEN 806-5:2012 & BS8558:2011 and in accordance with the GRI Estates department water sterilisation procedures along with SHTM 04-01 part E, and the entire new system(s) shall be subject to a leachate flushing regime, as detailed within SHTM 04-01 part E section 2 details the sequence for carrying out the procedure (NB – This is a 9 day process). Also as detailed within section 2 of SHTM 04-01 part E is the use of peracetic acid as a suitable disinfectant to be used when stainless steel pipe work has been installed. Prior to hand over, all pipework, valves including TMV's must be free from all Microorganisms, bacteria and viruses, including Pseudomonas, legionella etc. The contractor shall take due note and carryout this regime in accordance with SHTM 04-01 Part E.

Sterilisation and water treatment shall be carried out as part of these works by the client current incumbent contractor:

DMA Canyon Limited
14 Canyon Road
Wishaw
ML2 0EG

T - 01698 536790
E - office@dmacanyon.co.uk

345.000 SOIL WASTE DRAINAGE AND RAINWATER SERVICES

345.010 GENERAL

It is not envisaged that there will be a requirement to modify significant amounts of either Existing Soil Waste Drainage or Rainwater Drainage within the Ward 2A HOTCT, Ward 2A BMT and 2B DW areas, however Drainage facilities will have to be provided for the new Duty/Standby Supply and Extract Air Handling Units located within the new 4th Floor Plant room, to drain away the Condensate from the various Cooling Coils incorporated within the Supply and Exhaust AHUs (2 No Cooling Coils and 2 No Heat Recovery Coils). Details of minor modifications to the Drainage Services on levels 2 (Ward 2A HOTCT & Ward 2A MIBG area) and level 3 (Bed Store) are detailed on the Tender drawings.

350.000 MEDICAL GAS SERVICES

350.010 GENERAL

Works in connection with the Medical Gas Systems are all as generally detailed on the relevant Tender drawings and otherwise as described within the specification and other documentation forming part of the Tender package.

350.020 SCOPE OF WORKS

The scope of Works in connection with the Medical Gas Services include the following items in addition to other general Works specified elsewhere:

- 1 Inspection of all associated existing Medical Gas Services systems that may form part of the Works.
- 2 The verification of all Medical Gas Services pipework distribution systems and associated services that may have to be altered or otherwise modified as part of these works to accommodate the new proposed Ventilation or other Services that have to be installed as part of the Project Works.
- 3 The verification and recording of all appropriate existing certification relating to the Medical Gas Services systems that may be affected by the proposed alterations to the Medical Gas Services Systems, prior to the commencement of any disruptive works in connection with the existing associated Medical Gas Services.
- 4 The strip out and removal of all existing redundant Medical Gas Services systems and equipment as generally detailed on the Tender drawings together with all associated supports, etc.
- 5 The temporary or permanent isolations of all associated existing Medical Gas Services systems to ensure they can be set back to work promptly to meet the client's operational requirements for other areas that are served from common Medical Gas Services systems.
- 6 The installation of new Medical Gas Services systems as generally detailed on the Tender drawings, and as required to meet the specification, including Medical Gas Services pipework distribution systems, Isolating Valves, Pressure Regulating Devices, Pressure Gauges, etc together with all necessary supports.
- 7 The carrying out of all necessary specialist welding and jointing and other general installation work by a Specialist NHS approved Medical Gas Services Company who will be responsible for progressing the works strictly in accordance with the relevant SHTM guidelines for Medical Gas Pipework Installations, to fully comply with the requirements of the local NHS Estates Department.
- 8 The Commissioning/Balancing and general Setting to Work of the new and modified Medical Gas Services system including the provision of all appropriate certification.

350.030 DESCRIPTION

The Medical Gas Services works will be a contractor design element of the works, fully in compliance with SHTM 02-01 Part A. The Medical Gas Services layout shown on the Tender drawings is to indicate general design intent only, and the number and locations of outlets required together with locations for isolating valves, medical gas alarm panels, etc. The specialist design/build subcontractor will provide their own working drawings detailing all items that form part of their works including valves, bacteria filters etc. along with manufacturers technical literature for all system components for the design team's and local NHS Estates/ AE approval, prior to the commencement of any work on site.

The existing medical gas supplies serving Ward 2A as detailed, will be altered as pre required/detailed. The Specialist Medical Gas Contractor will carry out a full site survey of the relevant areas and allow for all appropriate remedial works to be carried out in connection with the Medical Gas Services to allow the necessary refurbishment Works to be progressed. Any penetrations formed through the building fabric as part of the works will be sealed and fire stopped where required and otherwise made good.

All Medical Gas Services works will be carried out in accordance with NHS Specification SHTM 02-01 Part A and QEH Estates Department Engineering Standards. All works to be undertaken by a recognised registered Specialist Medical Gas Services Contractor. Further reference should also be made to notes 1 to 9 on the relevant Tender Medical Gas Services layout drawing. The Specialist Medical Gas Services Contractor must obtain a full compliance verification check and authority to proceed from QEH Estates

and their AE prior to commencing work on site, and the Specialist Medical Gas Services Contractor must seek this within two weeks of main contractor appointment.

The existing Medical Gases installations will be modified as required to facilitate the installation of new M&E Services equipment essentially within the main Ward 2A HOTCT Corridor ceiling void area as generally indicated on the Tender drawings. It is envisaged that these works will be of a relatively minor nature involving modifications to some of the existing pipe runs.

All test certification for Specialist Gas Services Pipework Systems will be issued to the Design Team and the local NHS Estates Department and their AE for approval in a timeous manner to suit the Works Construction Programme.

355.000 SPRINKLERS

355.010 GENERAL

Works in connection with the Sprinkler Services Systems are all as generally detailed on the relevant Tender drawings and otherwise as described elsewhere within the specification and other documentation forming part of the Tender package.

355.030 SYSTEM DESCRIPTION

It is envisaged that the existing Sprinkler System serving Ward 2A Hematoma Oncology Teenage Cancer Trust, will have to be modified to suit the new proposed M&E Services layout proposed for that area. It is likely that alterations to the existing Sprinkler System within the Bedroom Suite and associated areas out with the main Ward Corridor will be of a fairly minimal nature. Every attempt will be made to maintain the existing ceiling level within the main ward corridor, however if as planned it is not reduced in height, this is likely to result in further general pipework modifications to the main pipework services contained therein, including the Sprinkler Pipework Services system, to accommodate the proposed larger Ventilation Ductwork. If the ceiling is however reduced in height the various branch connections to all heads, will have to be extended.

It is unlikely that any alterations will be required to the Sprinkler Services System within the Ward 2A Bone Marrow Transplant area due to the minimal amount of new works proposed for that area, although this may have to be further reviewed if other possible works for that area, that have not yet been fully defined, are developed.

It is also unlikely that any modifications will be required to the Sprinkler Services System within the Ward 2B Day Ward area due to the nature of the new works proposed for that area.

The main associated Sprinkler Zone pipework system serving the above areas will almost certainly have to be drained down, tested and refilled accordingly.

360.000 VENTILATION

360.010 GENERAL

Works in connection with the Ventilation Systems are all as generally detailed on the relevant Tender drawings and otherwise as described within the specification and other documentation forming part of the Tender package.

360.020 SCOPE OF WORKS

The scope of Works in connection with the Ventilation System will include the following items in addition to other general Works specified elsewhere:

- 1 Inspection of all associated existing ventilation systems that may form part of the Works.
- 2 The verification of all ventilation equipment and associated services that must be removed or temporarily laid aside for future use, as part of these works or for the client to use on some other project.
- 3 The verification and recording of present air flow rates on existing Ventilation systems prior to the commencement of any disruptive works in connection with the existing associated Ventilation systems.
- 4 The strip out and removal of all existing redundant Ventilation systems and equipment as generally detailed on the Tender drawings together with all associated supports, etc.
- 5 The temporary or permanent isolations of all associated existing ventilation systems to ensure they can be set back to work promptly to meet the client's operational requirements for other areas that are served from common Ventilation systems.
- 6 The installation of new Ventilation systems as generally detailed on the Tender drawings and as required to meet the specification, including Ventilation Ductwork distribution systems, Grilles/Diffusers, Volume Control Dampers, Fire/Smoke Dampers, Access Panels, Isolation Dampers, Air Heater Batteries, Attenuators, Air Handling Units, Extract Fans, External Louvres, Pressure Stabilisers, etc together with all necessary supports.
- 7 Works in connection with the modification of existing AHUs serving Ward 2A BMT and Ward 2B Day Ward, including removing existing Thermal Wheels, modifying/removing existing filter units, upgrading existing Fans/Motors/Inverter Drive Units and installing new HEPA and high efficiency Bag Filters, including the upgrade of corresponding power supplies where required.
- 8 The Sterile Cleaning of all Ventilation Ductwork internally forming part of the Works, strictly in accordance with the requirements of SHTM 03-01. All other Ventilation Ductwork surfaces should also be kept visibly clean and free from dust and general debris.
- 9 The Testing, Balancing and setting to Work of all new and existing Ventilation systems forming part of the Works.

360.030 SYSTEM DESCRIPTION

Within the Ward 2A Hematoma Oncology/Teenage Cancer Trust area it is proposed to initially remove all redundant Supply and Extract Ventilation ductwork and associated fittings serving the Bedroom Suites and the adjacent Corridor and general Service Areas, which includes most of the Ventilation ductwork within the Ward 2A HO/TCT area, as it is significantly undersized for the new proposed ventilation provision. The present existing common Ventilation ductwork systems will be blanked off close to the where the existing Supply and Extract Ventilation branch ducts serving the Ward 2A HOTCT connect to the common riser ducts. It is proposed that the existing common Supply and Extract system will thereafter be rebalanced such that it only meets the requirements of the remainder of the areas that the common AHU presently serves, being the other general areas on levels excluding level 2, and delivers a similar Ventilation provision to what these other areas are being provided with at present. A pre-commissioning check will be carried out to establish what the existing air flow volumes are prior to any system rebalancing work being carried out. It is expected that the total air flow volume demand for the common system will obviously drop and the air flow duties of the associated AHU Supply and Extract Fans will be

reduced to meet the corresponding fall in demand, by prudent adjustment of the corresponding existing frequency inverter speed control drive units.

It is proposed to provide new separate Duty/Standby Air Handling Units to solely serve Ward 2A Hematoma Oncology Teenage Cancer Trust area. These Air Handling Units will be housed within a new Plantroom located at 4th Floor level. Each AHU will incorporate Supply and Extract Fans (with external motors and Inverter Speed Drive Units), Motorised Isolation Dampers, LTHW Frost Coils, Chilled Water Cooling Coils, Main LTHW Heating Coils, Run-around Heat Recovery Coils, two pre-filters (M5 & F9) and a final HEPA filter (H12/H13). The precise filter types will be selected to meet the local NHS Estate preferences, taking into account all specific operational concerns for the site. It is proposed that the Supply and Extract units will be stacked to make efficient use of the available Plantroom space and mounted on 300mm high runner support beams to assist with spreading the weight of the units over the floor area. The associated Fresh Air will be drawn in via a wall mounted External Louvre and the Extract Air exhausted through the roof above via a low profile Penthouse Louvre. The Supply and Extract ventilation ductwork will be twinned together such that the corresponding Motorised Isolation Dampers will effectively isolate the de-energised Air Handling Unit. It is also proposed that easily cleanable non-shedding Noise Attenuators will be installed on the ventilation ductwork on the room side of the AHU to effectively reduce the in-duct noise levels within the corresponding Supply and Extract ducts. Appropriate attenuation will also be provided on the outdoor side of the AHU where required, should there not be sufficient means of attenuation provided by the component parts of the AHU and the corresponding Fresh Air and Exhaust Air Ventilation ductwork. Special care will be taken on the Fresh Air inlet, as it is recognised that the associated Intake Louvre is located directly above a general roof play area, however steps have been taken to negate any problematic noise issues, by installing appropriate attenuators and reducing the general intake velocity of the corresponding Fresh Air Inlet Louvre.

The new proposed Supply and Extract ductwork will drop down a newly formed riser duct within the 3rd Floor Bed Store to pass down directly into the Ward 2A HOTCT ceiling void. Automatic Fire/Smoke Dampers will be installed at both 3rd and 4th floor levels to maintain the present fire rated compartmentation requirements.

It is envisaged that all new proposed general Supply and Extract ventilation ductwork will then generally run down the central Ward 2A Corridor ceiling void, where individual Supply Air ducts will branch off to serve the Bedroom, etc areas and maintain the Bedrooms and other positively pressurised rooms at a positive pressure of either +10 or +20 Pa with respect to the Main Ward 2A Corridor, depending on the existing provision of any intermediate TCT Lobbies or other rooms, which would be maintained at an intermediate pressure between the Bedroom and the main Ward 2A Corridor. A Pressure Cascade facility will be provided to help minimise the contamination risks from within the Ward and general Hospital areas. The room pressures would be accurately controlled by means of wall mounted Pressure Stabiliser Units which will also effectively close when the corresponding room doors are operated, resulting in an outflow of air from the Bedroom to the Ward 2A Corridor from the Bedroom to a TCT Lobby, then to the main Ward 2A Corridor, where a TCT Lobby is provided. All Bedroom and Special Accommodation Area Supply Air branch ducts will be fitted with a LTHW Re-heater Battery to provide accurate control of air temperature within the corresponding Bedrooms/Special Accommodation Areas. Each Supply Air branch duct will also be provided with a Volume Control Damper for balancing, and a Motorised Gas Tight Control Damper for Room Isolation purposes. Appropriate Swirl type Air Diffusers will be installed at ceiling level within each Bedroom to help provide a good even temperature spread across the room and also help maintain appropriate minimum terminal air velocities. It is also proposed that the Supply Air Diffusers boxes should be capable of incorporating terminal HEPA filters to facilitate their possible easy installation at a future date if it is considered appropriate to do so by the client, either as part of this contract or at some time in the future, which would additionally offer a final stage of HEPA filtration prior to the Supply Air entering the Bedroom, etc areas and provide additional cross contamination infection control within the Ward area. Extract Ventilation for the Bedroom Suites and the general Ward areas will be via Ceiling mounted grilles generally located within the Ward Corridor area (it is not proposed to provide any extract grilles within the Bedrooms) such that the velocities of the outgoing air through either the closed or opened Bedroom door, can be maximised to assist with back contamination issues.

With regards to the Bedroom Suite Toilet Extract Ventilation provision it is proposed to reuse the existing Ventilation Ductwork as much as possible, as generally indicated on the Tender drawings close to where the existing branch duct on the main central station Toilet Extract system will be blanked off, and the relevant associated existing Central Station Toilet Extract Ventilation system recommissioned accordingly maintaining the present air flow volumes to the other areas outwith Ward 2a HOTCT area accordingly, albeit with a reduced total air flow duty. The proposed new Toilet Extract Ventilation System serving Ward 2A HOTCT will incorporate significant sections of the existing system located within Ward 2A HOTCT, however it will ultimately connect to a new separate Toilet Extract Ventilation duct which will thereafter rise up to the new proposed 4th Floor Plant room and connect to a new duplicate Duty/Standby Toilet Extract Fan Units, prior to rising up to discharge through the roof above, by means of a common low profile Penthouse Louvre.

Within the Ward 2A Bone Marrow Transplant area, it is proposed to essentially modify the present Air Handling Unit serving this area such that the existing Thermal Wheel Heat Recovery Device is removed, and the common interconnected opening blanked off, thereby virtually nullifying the risk of cross contamination between the Fresh Air Supply and the Exhaust Air Ventilation air streams. It is anticipated that some of the adjacent electrical lighting modular trunking system will have to be temporarily removed to facilitate the removal of the existing Thermal Wheels, which it is advised by the AHU manufacturer can be removed in part sections. Further proposed works to this AHU include the installation of final HEPA Filters (H12) on the Supply Section with F7 filters immediately upstream, to replace the existing F7/F9 final filters presently installed. In order to maximize the air flow of the existing Supply Ventilation System it is proposed to retain the existing fan unit, however upgrade the corresponding fan motor and inverter unit up to 11 kW, which is likely to result in a potential increase in the Air Supply Flow Volume of approximately 7.9%, or otherwise maintain the set existing air flow at a slightly higher system static pressure, which is likely to be required with an increase in the pressure drop of the new proposed final AHU HEPA filter unit. It should be noted that it is not considered possible by the existing AHU manufacturer, to further effectively increase the performance of the existing AHU in terms of air flow/static pressure beyond these quoted figures, due to space restrictions within the existing AHU.

Within the Ward 2B Day Ward area it is proposed to essentially modify the present Air Handling Unit serving this area such that the existing Thermal Wheel Heat Recovery Device is removed, and the common interconnected opening blanked off, thereby virtually nullifying the risk of cross contamination between the Fresh Air Supply and the Exhaust Air Ventilation air streams. It is anticipated that some of the adjacent electrical lighting modular trunking system will have to be temporarily removed to facilitate the removal of the existing Thermal Wheels, which it is advised by the AHU manufacturer can be removed in part sections. Further works to this AHU include the installation of final HEPA Filters (H12) on the Supply Section with F7 filters immediately upstream, to replace the existing F7/F9 final filters presently installed. In order to maximize the air flow of the existing Supply Ventilation System it is proposed to replace the existing fan unit with a new upgraded Direct Driven Unit with a corresponding 11 kW motor and inverter drive unit, which is likely to result in a potential increase in the Air Supply Flow Volume of approximately 19%, or otherwise maintain the set existing air flow at say a slightly higher system static pressure, which is likely to be required with an increase in the pressure drop of the new proposed final AHU HEPA filter unit. It should be noted that it is not considered possible by the existing AHU manufacturer, to further effectively increase the performance of the existing AHU in terms of air flow/static pressure beyond these quoted figures, due to space restrictions within the existing AHU.

The above modification works in connection with the existing Ward 2A BMT and Ward 2B Day Ward Air Handling Units will be carried out by:

Barkell Ltd.
Unit 22, No 1 Industrial Estate,
Consett, County Durham DH8 6SZ
Contact Tel 01207 590 575
Jamie Donald/P. Fenwick email: ahu@barkell.co.uk

(refer to existing quotation reference Nos AS3822 Rev 00 and AS3698 Rev 2 dated 25th Jan 2019 & 26th Nov 2018 respectively.

Please note that the works in connection with the corresponding Inverter Drive and Power Supply Cable Upgrades will be carried out by the Specialist Controls Contractor as part of these Works.

Part of the Ventilation Works involves a requirement to install additional Smoke Dampers, and interface them with all existing associated Power and Controls systems. All necessary work in connection with extending or otherwise modifying the existing Smoke Damper System (including the installation of new Smoke Dampers and associated Controls and Power and Controls wiring will be carried out by:

Entropic Ltd;

Contact:

365.000 PNEUMATIC TUBE SYSTEMS

365.010 GENERAL

Works in connection with the Pneumatic Tube Systems are all as generally detailed on the relevant Tender drawings and otherwise as described elsewhere within the specification and other documentation forming part of the Tender package.

365.030 SYSTEM DESCRIPTION

It is envisaged that the existing Pneumatic Tube System serving Ward 2A Hematoma Oncology Teenage Cancer Trust area, will have to be modified to suit the new proposed M&E Services layout for that area. It is likely that alterations to the existing Pneumatic Tube System within the Clean Utility/C. Drugs/C.Bay area outwith the main Ward Corridor will be of a relatively minimal nature. Every attempt will be made to maintain the existing ceiling levels within the main ward areas, however this is likely to result in modifications to the Pneumatic Tube System pipework runs as generally detailed on the Tender associated drawings to allow the installation of the proposed larger Ventilation Ductwork.

It is also envisaged that there will be modification works required to the Pneumatic Tube Systems within the ceiling void of the Ward 2A Corridor area adjacent to the Clean Utility/C.Drugs/C.Bay area, to facilitate the installation of new proposed M&E Services therein.

It is however unlikely that any alterations will be required to the Pneumatic Tube System within the Ward 2A Bone Marrow Transplant area due to the minimal amount of new works proposed for that area, although this may have to be further reviewed if other possible works for that area, that have not yet been fully defined, are developed.

It is also unlikely that any modifications will be required to the Pneumatic Tube System within the Ward 2B Day Ward area due to the nature of the new works proposed for that area.

390.000 CONTROLS

390.010 GENERAL

The Works in connection with the Controls element of this project form part of the Mechanical Services Contract Works Package for QEUH Royal Hospital for Children, Glasgow.

Further reference should also be made to the various other relevant sections of the specification for details of all General Preliminaries and Contract Conditions associated with the Works. These other sections also provide details on the general scope of the Complete Works Package, together with information on the general Project Requirements.

It is envisaged that the Mechanical Services Controls element of the works will be split into two main works packages. One essentially relates to the provision of a new autonomous BMS Controls System that serves Ward 2A Hematoma Oncology Teenage Cancer Trust area which is served from four new Mechanical Services Control Panels located within the new 4th Floor Ventilation Plant Room, together with a Nurses Control Panel located at the Nurses' Station within the Ward 2A Corridor. The other Controls Works Package relates to modification work in connection with Existing Controls infrastructure services, which will have to be either altered or partly replaced to meet the specific requirements of the Outline Specification, which includes Power and Controls Work in connection with the modified Existing Air Handling Units serving Ward 2A BMT and Ward 2B Day Ward. Other potential future works that may be incorporated into the Controls package as part of these works include works in connection with the new proposed NPVL SCH010 Room, which have not as yet been fully defined. The Controls and associated Power Works in connection with the proposed NPVL SCH010 Room will be covered by a Provisional Sum, at this stage.

The Control Panels will be located generally where shown on the Tender Issue drawings, however their precise location will be determined following detailed consideration of maintenance and general access requirements to all plant and equipment (and thereafter agreed with the CA in conjunction with the local NHS Estates Department). The Electrical Power supplies to the new Control Panels will be provided by the main Electrical Services Contractor. These will be all be taken from an appropriate Essential Services Power source within the Royal Hospital for Children Building. It should be noted that each Mechanical Services Control Panel will be provided with an integral UPS Unit to help ensure a smooth change over when the Standby Ventilation Plant is energised in a power fail situation (this will allow the initial Duty Unit to shut down and be isolated appropriately). A 15 kVA@ 3 minutes 3 Phase UPS unit will be allowed for each of the two main Ward 2A HOTCT AHU Control Panels, and a 6kVA @ 3 minutes 1 Phase UPS will be allowed for each of the smaller Toilet/Dirty Extract Control Panels. Connections from the RHC Building's Comms Cable (WAN line) to each new Control Panel, will be carried out by others, out with these Contract Works.

In addition to providing appropriate HVCA Controls and Power supplies from the four Ward 2A HOTCT Control Panels to the two new Air Handling Units and the two new Toilet/Dirty Fans and associated equipment housed within the new 4th floor Plant Room, C&P supplies will have to be taken to field mounted equipment located either within or adjacent to the various Bedrooms and other accommodation areas. C&P supplies will also have to be taken to a Nurse's Station Control Panel, located within the Nurse's Station area of Ward 2A Corridor. This new Control Panel will provide Room Pressure monitoring and alarm facilities for the various Bedrooms and other associated accommodation areas within Ward 2A HOTCT area. Due to an increased Power requirement in the power supplies to the existing AHUs serving Ward 2A BMT and the Ward 2B Day Ward AHUs, an allowance will be made for new increased power supplies to the associated Supply Fan Motors, in addition to Controls Supplies to the new Filter facilities. It is likely that other Controls and associated Power works will be required in connection with the new proposed NPVL SCH 010 Room within the Ward 2A BMT area, however as this has not been fully defined as yet, associated costs will be covered by a Provisional Sum Allowance, for the time being.

Reference should be made to other sections of this specification together with associated Tender Drawings for general details of all works that are to be included as part of this Contract (including strip-out/removal works, temporary works, etc).

The Contract also includes for all necessary isolation, down takings and removal works in connection with the existing M & E Services. The Main Contractor will also allow for all necessary down takings and removal works in connection with the Building Fabric, as part of this Project.

All M&E Services systems will be installed, commissioned and set to work in full compliance with the requirements of the specification. All appropriate documentation required as part of these works, must be issued to the Client in advance of the project being officially handed over. All critical (as determined by the CA) snagging or outstanding works that requires to be completed for the operation of the Ward 2A HOTCT, Ward 2A BMT and Ward 2B Day Ward areas covered by this Contract must be carried out satisfactorily prior to project handover, in order that the follow-up Client's Validation Works can be progressed to suit the overall Client's Works Programme.

The Specialist Controls Contractor will fully assist the Mechanical Services Contractor with issues such as temporary shutdowns of existing Plant throughout the progress of the Contract, to meet the client's precise operating requirements.

As part of this Contract it will also be necessary for the Mechanical Services Contractor to liaise with all other specialist contractors and sub-contractors carrying out the works required to complete the Contract, including works not specifically described in detail within this particular specification, however that are otherwise required to complete works in connection with the Contract as a whole. Reference should also be made to other Client's Tender Documentation made available for the pricing of these works, such that due cognisance will be taken of these items in the preparation of the Contract Tender Cost. There will be a significant Builders work element, which will be detailed elsewhere within the Contract Tender Documentation Package. These works will include the forming and making good of various significant holes through the existing structure to facilitate the installation of the M&E Services Installations. Other general builders work including work in connection with the ceilings, walls and general building fabric, including redecoration works, will also be carried out by others outwith the Mechanical Services Works Package and is therefore detailed elsewhere within the Contract Tender Documentation Package. Other Works of a more minor nature in connection with fixings of supports for the Mechanical Services Plant and equipment to the existing structure, will be carried out by the Mechanical Services Contractor.

Following the award of the Contract any existing non-compliant issues, or matters of concern that are uncovered on site, should be highlighted to the Engineer/Contact Administrator at the earliest opportunity to allow due consideration to be made and appropriate remedial action taken.

It is important that operation of the adjacent areas within the hospital are not unduly compromised, and it likely that the Local NHS Estates personnel will strive for only an absolute minimum amount of shutdowns over the shortest permissible periods. These restrictions are further detailed elsewhere within the specification. It should not be expected that other extended shutdown periods will necessarily be either granted or agreed with the NHS Estates Department, therefore every feasible attempt must be made to comply with these parameters. All reasonable means will also be made to minimise the extent of on-site work within the Ward areas to minimise the impact the works may have on the other areas of the hospital, and also to help minimise the length of the Construction Programme period. Adjacent Wards must be able to continue to operate throughout the progress of these contract works, in a fashion that permits the general proper ongoing operation of their duties with minimal impact on the patient's or staff's general comfort.

The Mechanical Services Contractor and Specialist Controls Contractor will take full cognisance of all information contained within the Specification and Tender Documentation package including information included on all relevant Tender drawings and comply fully with all stated requirements, however due allowance should also be made for other equipment not specifically indicated or shown, but that is required for a full and complete system to enable it to perform its design task of operating and monitoring the complete Mechanical Services Systems and other associated equipment.

390.030 DESCRIPTION

The description and operation of the new proposed M&E Services Power and Controls Systems are generally detailed below, to give an overall appreciation of the way the M&E Services installations operate and interrelate with one another. The existing Essential Services Power Systems will serve the new Ward 2A HOTCT Ventilation Plant and associated Controls systems, such that they will continue to operate under general mains Power failure, or additionally if one of the Essential Services Power Cables are compromised in some way. Also, if there is a failure in any component part of the main Ventilation Plant, a standby Ventilation Plant will be installed as part of these works, to provide back-up facilities automatically, within a reasonably short period of time, following Duty Plant failure.

General reference will be made to the Controls Points Schedules and corresponding Controls Equipment Lists for further specific details of the Controls equipment required for each HVAC system. It is expected that all control routines and staged alarm facilities will be programmed, and the necessary software provided to properly operate the M&E Services systems in connection with these works, and that all monitoring and staged alarm functions will be relayed to the existing BMS Front End. It should be noted that extensive use will be made of Virtual Switching/lights facilities, although there are some exceptions as identified within the Controls Points Schedules and the Controls Equipment Lists. The precise location of all control panels will be determined on site with the agreement of the local NHS Estates Department, however general regard will be taken at Tender Stage of the approximate locations of the Control Panels as indicated on the Tender Drawings.

All necessary Containment and Electrical Power and Controls Supplies will be provided for the new and existing upgraded HVAC Controls Systems and associated equipment from the various new and existing Mechanical Services Control (and associated Power) Panels, forming part of the Mechanical Services Contract. The main Electrical Services Contractor will allow for providing new additional separate Electrical Power Supplies to each of the new Control Panels serving the duplicate Supply and Extract Ward 2A AHUs and the associated duplicate Toilet Extract fans. These additional power supplies will be taken to individual isolators mounted on the wall adjacent to the proposed new Mechanical Services Control Panel locations within the new 4th floor Plant room. The Specialist Controls contractor will allow for taking the power from these points up to the various Mechanical Services Control Panels.

The automatic controls system will be of the DDC type comprising of an appropriate number of network controllers and field processing units/outstations which will be capable of stand-alone operation. The FPU's/outstations will also be fully networked such that all units may be interrogated from a portable operator's terminal/keypad connected into any FPU/outstation unit.

The Specialist Controls Contractor will provide a complete Controls and associated Power Installation that is fully and readily compatible with the existing installations on site, including all associated software provision. And be fully responsible for fully setting the systems to work ready for final client Validation.

The Mechanical Services Controls System serving Ward 2A Hematoma Oncology Teenage Cancer Trust area is essentially autonomous in nature, in that it can carry out its duties without any input from the main central Hospital's BMS System, although it must be fully interfaced with the main Hospital's BMS in such a way that all points can be monitored, and the various systems controlled and adjusted remotely from the main BMS. Alarm conditions must also be capable of being picked up by the main central BMS Front End facility. It is understood the Ward 2A Controls System will be connected to a site wide BMS by means of an appropriate Comms Cable infrastructure system, as part of a separate Client's Works Package.

All necessary interlocks will also be provided with the building's fire alarm system to meet the requirements of the local Fire Officer, although the wiring of such will also be carried out as part of the main Electrical Services Works Package.

The new and upgraded existing Supply and Extract Air Handling Units and other associated plant and equipment is designed to meet all basic operational requirements of the new and upgraded facilities, however the precise duty performance of equipment such as Inverter Drive Units will have to be further adjusted as part of the commissioning process to generally meet the precise duty requirements of the

Pressure Cascade Ventilation System forming part of the new HVAC system serving Ward 2A HOTCT, together with the general requirements of the upgraded Ventilation Systems serving Ward 2A BM and Ward 2B. The duplicate Standby Supply and Extract AHUs and will both incorporate single Supply and Extract external motors with individual Inverter Drive Units, to efficiently regulate the speed of the various fans to provide the correct air flow rates and room pressures for the new Ward 2A HOTCT facility. The associated Ward 2A duplicate Toilet Extract Fan Units are similarly designed to meet the duty requirements, however further adjustment will be required to meet the precise Air Flow and room pressure requirements for the new HOTCT facility.

It should be noted that the speed of the new Ward 2A HOTCT AHU Supply Fans will be regulated by means of their associated local individual Inverter Drive Units to maintain specific constant static pressure levels for each supply air system. In the event of a single motor/inverter drive failure or other significant failure in connection with the Duty AHU, the corresponding standby AHU will be arranged to automatically energise, with a fail alarm being generated. All new Frequency Inverter drive Units will be mounted externally to the corresponding Supply and Extract AHU Units, to efficiently regulate the speed of the fan to provide the correct air flow and room pressures for the various Bedroom, etc areas.

This will be regarded as a Critical Alarm condition which will momentarily disengage the general room low pressure alarms until a set time has elapsed whereby the Standby AHU will be expected to be made fully operational (and up to speed). The failure of any significant plant item in connection with the Duty AHU (or its associated Heating/Chilled water Controls), will instigate a shutdown procedure for the associated Duty AHU to effectively isolate it from the general Ventilation system, which will include the closing of associated Ventilation Isolation Dampers, S&E Fans and corresponding Heating, Control Valves, etc., in a controlled and methodical manner that will avoid problematic operating issues. The starting procedure for the Standby AHU will then be progressed in a sequenced manner such that the associated standby Heating and Cooling Valves will energise, and the corresponding Ventilation Isolation Dampers will open and engage the associated end switches, to allow the main Standby Supply Air Fan to ramp up to the appropriate speed and stabilise under control of its corresponding Air Pressure Sensor.

Three stages of air filtration will be provided for the new Ward 2A HOTCT duty and standby Supply AHUs, and Single stage air filtration will be provided for the new Ward 2A HOTCT duty and standby Extract AHUs; Primary Filtration (M5) will be provided within the Supply AHUs prior to the Heat Recovery Coil (M5) and further F9 and HEPA filtration will be provided at the end of the Supply AHUs, and Primary Filtration (M5) will also be provided prior to the Heat Recovery Coil on the Extract AHUs, all as generally indicated on the Tender Drawings. The pressure drops across all filters units will be individually monitored by Differential Pressure Sensors to provide an indication of their individual operating condition and trigger an alarm when the corresponding pressure drops approach their associated desired terminal operating limits.

New Motorised Control Dampers will be provided on the both the intake and discharge side of the various new duty and standby Supply and Extract AHUs and Toilet Extract Fans as generally indicated on the Tender Drawings, to effectively close all appropriate Intake and Discharge Dampers on each corresponding AHU or Extract Fan when they are de-energised. This facility may also be used to help isolate the Ventilation Plant for general maintenance purposes including possible plant cleaning. The use of non-electric backdraught dampers may also be considered in the future to decrease the Changeover Time if deemed acceptable by the client. The corresponding Fan Units will be prevented from operating when their corresponding dampers are not properly opened (and the end switches made).

Frost Control routines will be incorporated where required into the controls software system that provide multi-level protection against Coil/pipework freezing, and other potentially problematic low temperature events. Frost Coils will be provided for each new duplicate Supply AHU, which are designed to provide an off coil condition of 5°C db with an external design temperature of -10°C/sat, although consideration may be given to dropping the off-coil temperature slightly; perhaps around 3°C following general agreement from the local NHS Estates Department, to maximise the heat pick-up from the downstream Heat Recovery Coil. Frost Thermostats will also ensure the Heating Valve opens during Frost Conditions on a proportional basis. A pipeline mounted Police Sensor will ensure hot water is circulated through the

Frost Coils when required at low temperature conditions, prior to allowing the corresponding Supply Fans to operate. The new duplicate Ward 2A HOTCT Supply and Extract AHUs also both incorporate Run around Coil Heat Recovery Systems incorporating a single Circulating Pump and a corresponding 3-port Control Valve, as part of a packaged Run Around Coil Heat Recovery Unit provided by the AHU manufacturer/supplier. The Heat Recovery Coils will be designed to raise the Supply Air temperatures up to a minimum of approximately 13°C at the external Winter design temperatures, or up to approximately 18°C where the external temperatures are higher, however not when Cooling is required. Additional Control and monitoring facilities will be provided for the Ward 2A HOTCT AHU and Toilet Extract Control Systems, as generally indicated on the Tender Drawings. A sequenced Heating facility will be provided to meet the Heat demands of the space as economically as possible, however the Primary Frost Coil must not be prevented from ensuring that the off-coil temperature is no less than a set minimum value (which has notionally been set at 5°C at design stage. It is also important that when there is a cooling demand in the space that the supply air temperature is not unnecessarily raised to a temperature where it has to be thereafter lowered by the Cooling Coil within the Supply AHU. The Heating output of the Heat Recovery Coil may have to be regulated by diverting Heating Water from the H/R Coil. A transitional stage will be incorporated where the Heat Recovery Device is effectively isolated when full use is to be made of free Cooling to meet the Cooling Demand of the space. When the external temperature thereafter rise to an exceptionally high value the Controls system will allow effective and controlled Pre-Cooling to take place at the Heat Recovery Device operating in reverse. When Cooling is otherwise required from the Chilled Water Cooling Coil It will be arranged for it to lower the Supply Air temperature from 28°C db/19.5°C wb to approximately 14.5°C db/13.5°C wb, when it may thereafter pick up approximately 1.5°C in sensible gain thereafter, prior to supplying air to the various accommodation areas.

The Heating and Cooling output of the corresponding Heating, Heat Recovery and Cooling Coils will be regulated by altering the position of a corresponding Control Valves mounted on the associated pipework systems serving the Coils. The various Heating, Heat Recovery and Cooling Coils will operate under the dictates of their corresponding duct mounted temperature sensors mounted downstream of the various Coils with appropriate input from other Room and Duct mounted Temperature Sensors to fully evaluate the Heating and Cooling load requirements.

Appropriate Reheat will also be made possible from the following main Heater Battery where required, if specific dehumidification is required due to high humidity levels detected within the general Return Air Duct from the accommodation areas. The Heating and Cooling Coils will be capable of being controlled to provide a sliding dew point control for limiting the upper humidity levels whilst at the same time providing close db temperature control of the Supply Air. It should be noted that if the Heat Recovery System fails for some reason, the Main Heating Coil is designed such that it will still be able to raise the Supply Air Temperature within the Air Handling Unit to at least 18°C at the external Winter design temperature of -10°C/saturated. When there is a general heating load requirement within the Ward 2A areas the various LTHW Re-Heater Batteries will operate under the dictates of their various local Room Temperature Sensors to meet the heating demands of their respective rooms, by the automatic adjustment of the various corresponding local Heating Control Valves. It will be possible to adjust the Room Temperatures set point value for the various Bedroom, etc areas by means of limited adjustment locally of the local Room temperature controller units (although limits to this will be set by the local BMS System to avoid indiscriminate tampering). Cooling to the various Bedroom, etc areas is provided by Central Cooling with input from the local Room Temperature Sensors. It is however important that the Cooling provision will be carried out as economically as possible, with the air flow volumes having been adjusted slightly to cater for the various different room cooling loads of the various rooms concerned. It is however acknowledged that some re-heating will be required in certain circumstances especially if close temperature control is desired within the various temperature controlled Bedrooms, etc., however the facility of building in some flexibility with the acceptable range of room temperatures will be built into the Controls Software to help minimise wasteful re-heat.

It is assumed that the existing Central Chilled Water Cooling System operates the associated existing Chiller Units in a stepped manner where appropriate, to meet the varying Cooling Load requirements. throughout the year and vary the corresponding Chilled Water flow rates accordingly. It is also

understood that the existing Chilled Water system essentially operates essentially at constant Chilled Water Flow and Return design temperatures of approximately 8°C flow and 14°C return.

The two new main AHUs serving Ward 2A HOTCT area are provided with individual Run-Around-Coil Heat Recovery Systems incorporating a Circulating Pump, 3-Port Control Valve, Temperature Sensors, etc which should be provided in a general kit form on a rig, by the AHU manufacturer. The Heat Recovery Systems will both be provided with automatic water make-up facilities in the form of a Pressurisation Unit, all located within the new 4th Floor Plant Room.

Air Flow Static Pressure sensors will be installed downstream of the various Supply and Extract Fans (final location of the pressure sensors will be determined on site). Additional corresponding differential pressure switches will otherwise prove the general satisfactory operation of the Supply Fan. Any significant issues relating to air flow will initially raise a first stage alarm on the BMS and thereafter be capable of shutting down the associated Ventilation System at a pre-set condition.

A Digital Electronic Differential Pressure Monitoring and display system will be provided to record the differential air pressure across the various Bedroom/Corridor, Play Room/Corridor and Contingency Room/Corridor compartments within the Ward 2A HOTCT areas. The individual room Air Pressure Monitoring Devices will be located within the ceiling voids immediately adjacent to each of the corresponding Pressure Controlled Rooms. Each Air Pressure Monitoring Device will be connected to two ceiling mounted Air Probes (c/w Stainless Steel Facia Plates) by means of appropriately coloured PVC Tubing. A pair of Air Probes will be provided for each Pressure Controlled Room, with one being mounted on the ceiling of the Pressure Controlled Room and the other on the ceiling of the adjacent Corridor. Individual Stainless Steel (recessed facia plate) Digital Pressure Display Units will be provided for each pressure controlled room, to be mounted on the wall of the adjacent Corridor to the Pressure Controlled Room. The DPDUs will be designed to show the original design room pressures/pressure differentials and the corresponding actual room pressures/pressure differentials with a clear indication of any deviations. Time related alarm signals will be generated to indicate either unacceptable long term or short term deviations, which will be clearly identified on a Colour HMI Display Unit mounted on the facia of the local Nurses Station Control Panel. An historical logging facility will be provided to record ongoing pressure conditions and alarm events for all DPDUs, which will be housed within the Stainless Steel Nurses Control Panel. The capacity for event recording and time intervals for pressure recording will be proportionally similar to the existing facility provided for Ward 2A BMT area, which is expected to cover a period of approximately 14 months. A 24 hr battery back-up provision will be provided for the Pressure logging facility, with an indication lamp showing mains power failure.

All necessary power supplies for the will be taken from the local KNX small Power supply Network.

In addition to the Controls and associated Power installations in connection with the upgraded Ward 2A HOTCT area, there is a requirement to modify the existing Controls and associated Power installations in connection with the alteration to the existing Ward 2A Bone Marrow Transplant and Ward 2B Day Ward Air Handling Units, where the existing Thermal Wheel Units will be removed and the existing F7/F9 Bag filters replaced with new final F7 Bag Filters and H12 HEPA Filters immediately downstream. Individual monitoring of each filter will be required by means of differential Pressure Sensors, to accurately assess the requirement for the replacement of each individual filter, as the replacement or cleaning periods of both will vary significantly. The Specialist Controls Contractor will also be responsible for the provision of new upgraded Inverter Drive Units for the two upgraded AHU Supply Fan Motor concerned, together with the necessary upgrading of the corresponding Power Supplies to the Inverter Drive Units and the new associated upgraded Supply Fan Motors. Work in connection with making good the existing Controls associated with the proposed removal of the Thermal Wheels should also be allowed for. It should be noted that the general refurbishment works in connection with the two existing AHUs, will be carried out by the original AHU manufacturer (Barkell Ltd – refer to Ventilation section of the Particular Specification for further details).

The provision for monitoring the various Air/Water Temperatures, Pressures Humidifies and alarm events will be recorded on the main BMS Front End facility for the building. Corresponding Sensors and other Controls Devices will be also be provided where indicated on either the Tender Drawings or where additionally noted on the following Controls Schedules below:

BUILDING MANAGEMENT SYSTEM

1. General:

All Automatic Controls works will be carried out by an NHS approved Specialist Controls Contractor, who must also comply with the following requirements.

The Building Management System (BMS) will be designed to control and monitor the complete HVAC Controls system.

The new controls will be fully BACnet compliant and truly fully open protocol. All new installed controls systems will be capable of sitting on and fully interfacing with the client's BOWS (BACnet Operator Works Station).

Each project must be incorporated into the current BMS system architecture within the hospital or NHS facility concerned. Due care and attention must be taken when connecting to the sitewide Ethernet network. The Specialist Controls Contractor must arrange meetings and otherwise properly liaise with the Works Contractor together with the appropriate local NHS IT Department to ascertain the relevant IP Addresses, etc.

The products being supplied as part of this contract must be approved through ASHRAE and BacNet Testing Laboratory (BTL) and this must be evidenced prior to the Controls Contract being awarded. The products being supplied must have the BTL trademark together with the relevant BacNet logo.

The nomenclature or naming convention to be used within the engineering strategy is to follow the IES naming strategy carried out previously on the QEUH Royal Hospital for Children Site. Full details are available by contacting IES direct.

Cognisance must be taken to ensure the following under listed tasks are carried out prior to, during, and after project completion:

2. Network Architecture Drawing:

NHS Energy Team (and on some sites the Hospital Estate Officers) are in possession of a Boardwide/Sitewide system architecture schematic drawing. This drawing MUST be updated with any new or modified projects immediately following completion of the project. Items to be detailed on this drawing are:

- Controls Contractor Name & Address
- Project Ref No.
- Project Description
- Project Location
- Controllers Utilised
- Spare Point Identification & Quantity
- Network IP Address

3. Conformity Document

Prior to the engineering of the project software, a Conformity Document will be produced/shared and tabled at a meeting with the relevant project/estate officer/energy manager. The purpose of this document is to maintain the agreed format of works/graphics/settings etc for each new project installed on the site.

On completion of the project, this document will be signed by the Controls Contractor, NHS Energy Manager and the Site NHS Estates Manager (on the assumption that all information is correct, and works have been carried out to an acceptable standard).

All nomenclature within the control strategies will be in the IES agreed format to allow for future monitoring of set points etc.

This document will confirm and highlight the following:

- Graphical Representations – Font colour, size, format etc
- Project Ref No, Description, IP Address, Location on Network, etc
- Time Schedules, Setpoints, Values, Limits, Alarm Levels etc
- All points utilised and associated units of measurement, etc.

4. Description of Operation Document (Des Ops)

A Des Ops is to be supplied, which will describe the operation of the plant/equipment under the control's strategy. This Des Ops will be agreed with the on-site Estates Operational team together with the relevant Energy Manager. It will be described in laymen's terms and have any associated drawings in place to support the Des Ops.

5. Operating & Maintenance Documentation

On completion of any project or modification, an Operating & Maintenance manual will be produced and issued to the relevant Estate Officer. This manual will consist of the following items/sub-sections:

- Complete set of Controls/Control Panel As-Fitted drawings;
- Full description of operations (as previously agreed with Estate Officers/Consultants);
- Full listing of data sheet documentation (associated with each item of equipment utilised on the project);
- Commissioning Report (detailing all setpoints, alarm levels, time schedules, etc)
- Full set of software drawings and back-up of same (memory stick to be handed over with Operating & Maintenance Manual);
- Conformity Document (as detailed previously);
- DesOps Document;
- Graphical print out of all associated graphical representations shown on the BMS Command Centre(s).

6. Naming Convention

The tenderer must provide consistency of approach through consistent nomenclature in their tender return. Please refer to naming convention below for guidance. NHS GG&C will work with the successful bidder to ensure that an agreed naming convention is used post-award.

The naming convention template is identified below:

BMS NAMING CONVENTION

Plant/Software Point	Datalog Name	IES TAGS
Temperature Sensor	DhwPheDuty1FlowTemp	#Temp #heatExchanger #flow
Enable	DhwPheEnable	#enable #domestic # enable
PHE Output	DhwPheSignal	#heatExchanger
Temperature Sensor	DhwPheDuty2FlowTemp	#run #domestic # heatExchanger
PHE Output	DhwPheSignal	#Temp #heatExchanger #flow
Enable	DhwPheEnable	#run #domestic #heatExchanger
Temperature Sensor	DhwPheStandbyFlowTemp	#enable #domestic #heatExchanger
Enable	DhwPheEnable	#Temp #heatExchanger #domestic
PHE Output	DhwPheSignal	#domestic #heatExchanger #enable
Temperature Sensor	DhwsCommonFlowTemp	#run #domestic #heatExchanger
Temperature Sensor	DhwsCommonReturnTemp	#Temp #domestic #flow
Temperature Sensor	ColdWaterSupplyTemp	#Temp #domestic #return
Enable	DhwsSecPumpEnable	#Temp #water
		#Temp #domestic #enable

Example or Spelling Errors	Common Name	IES TAGS
Boiler 01 Flow Setpoint	Boiler 01 Flow SP	#Boiler #Flow #SP #heat
Boiler 02 Flow stpt	Boiler 02 Flow SP	#Boiler #Flow #SP #heat
Boiler 03 Flow SP	Boiler 03 Flow SP	#Boiler #Flow #SP #heat
Boiler 04 Flow sp	Boiler 04 Flow SP	#Boiler #Flow #SP #heat

Notes:

1. Common Name does not need to use precisely the same text, however it still needs to allow for enough flexibility to differentiate between points on-site i.e. Boiler 01, 02, 03, 04
2. Common Name should contain enough key word text (without spelling errors) that allow the manual or automatic generation of #Tags.
3. Manual Tagging can be time consuming and is easy to miss all eventualities. So automated Tagging derived from Point Name is preferred option, but point name needs to be considered from outset.

7. Command Centre and Web Server

On completion of new (or modified) works, each Command Centre on the network (together with the associated Web Server) must be updated in line with the latest software. Due care and attention must be taken such as not to hinder the operation of ongoing projects when updating these PC's. Estate Officers must be notified of any updates taking place in order to make them aware of any access issues raised by End Users during this time.

8. Design Engineering

Prior to works commencing on the software design for each project, the Controls Contractor must liaise with either the Design Consultant or the relevant Energy Manager/Estates Officer (depending on the design responsibility). The Controls Contractor will obtain the relevant information from this meeting in order to commence with the software design for the project. This design will also form part of the Operating & Maintenance document and will also be incorporated within the Conformity Document.

9. Control Panel Types

Where new control panels serve power to motive equipment (such as pumps, fans etc), these panels will be of the Form 2 type (power/control sections). This will allow access to be gained to the control section of the control panel without the need for isolating the power distribution section. In the case where new BMS controllers are purely replacing existing controllers, then a single enclosure will be acceptable. Normally, the power supply serving this single enclosure will be installed by the Estates Department.

10. Graphics

All new graphical displays created for installation onto the Command Centres and Web Server will follow the standard of the current graphics already installed eg:

- Air Filter Displays: In all cases, Differential Pressure Sensors will be installed in lieu of Differential Pressure Switches; this will enable the graphical representation to show a 'traffic light' indication system. Whereby, Green will show a clean filter, Amber will show a filter nearing the change period & Red will show a filter dirty.
- Valve Actuators: In all cases, where the percentage open of a valve is displayed, it will take the form of a fill box (Blue for Chilled Water and Red for Hot Water).
- Pump Trip Conditions: These will be shown as a flashing Red trip indication when activated.

11. Demonstration/Training

Following completion of new/modified projects, the Controls Contractor will carry out a full demonstration of the new BMS equipment and plant interfaces to both the consultant and relevant Energy Manager/Estates Officer. Demonstrations of how to interact with the graphical displays via the Command Centres will also be reviewed as required.

12. Alarm Handling & Notification

Meetings are required to be arranged with the Design Consultant and/or the Energy Manager/Estates Officers in order to ascertain the alarm requirements for particular projects. Further to this meeting, the Controls Contractor will detail all relevant alarms on the Conformity Document, which will then be reviewed and signed off by the Site Estates Manager & the Energy Manager.

13. Data Logging & Archiving

Data logging will be set up to incorporate all software points for daily archiving, then prepared for exporting into Open Building Information Exchange (oBIX) files. Files will automatically be transmitted to the Client's central B-OWS and also to an outgoing Email account.

WARD 2A HOTCT AHU 1 SYSTEM

CONTROL PANEL

Supply and erect a wall mounting enclosure having split power and control sections sized overall approximately 1200mm high x 600mm wide x 260mm deep each section having dust tight lockable access doors and finished externally with structure powder paint light grey RAL7035.

POWER DISTRIBUTION

- 1 TP&N Main Isolator – Door Interlocking – 4 Pole
- 1 TP & N Mains Distribution Block

SUPPLY UNIT

1	TP MCB
1	Variable Speed Drive – Located adjacent to fan
6	Control Relays
1	Run Lights
1	Trip Lights
1	Duct Frost Trip Light
3	Filter Dirty Lights
1	Off/On/Auto Switch

EXTRACT FANS

1	TP MCB's
1	Variable Speed Drive – Located adjacent to fan
2	Control Relays
1	Run Lights
1	Fault Lights
1	Off/On/Auto Switch

CONTROLS

1	BMS Outstation – Refer to Points Schedule for Details
1	Network Controller
1	System Access & Display Panel
1	Socket Outlet – Service Engineers Equipment
1	230/24 Volt Transformer
3	Control Circuit MCB's
1	Building Fire Alarm Circuit Relay
1	Common Fault Light
1	Panel Live Light
1	Control Circuit Live Light

PANEL WIRING & LABELLING SPECIFICATION

All of the above to be prewired in colour coded LSF cables with all outgoing cables terminating at a Klippon terminal strip. Cable ends to be identified by 'Z' type cable markers and all equipment to be identified using ivory designation labels.

All lights and switches specified are to be virtual with the exception of common fault and panel live lights and are to be viewed and accessed via the System Access & Display Panel.

AUTOMATIC CONTROLS

Supply and erect the following automatic controls (pipeline mounted equipment to be handed to BS Contractor for fitting).

SUPPLY UNIT

1	Variable Speed Drive – Located adjacent to fan
1	Air Flow Proving Switch (DPS)
3	Filter Differential Pressure Sensors (including a HEPA unit)
4	Damper Actuators c/w Auxiliary Switches
1	Duct Frost Thermostat
4	Motorised Control Valves (40/40/50/65mm dia)
5	Duct Temperature Sensors
1	Duct Frost Stat
1	Immersion Police Temperature Sensor

1 Air Static Pressure Sensor

EXTRACT UNIT

1 Variable Speed Drive – Located adjacent to fans

1 Air Flow Proving Switch

1 Filter Differential Pressure Sensor

1 Duct Temperature Sensor

1 Duct Temperature/RH Sensor

1

PRESSURE MONITORING SYSTEM

The new Pressure Monitoring System will be designed to measure air pressures within the various rooms covered together with pressure differentials across the various Bedroom-Ward Corridor, Bedroom-TCT Corridor, Play/Dining Room-Ward Corridor and Contingency Room-Ward Corridor compartments. Room Air Pressure Sensors/probes with Stainless steel mounting plates will be located on the ceilings of the various rooms served. These will connect to an Air Pressure monitoring device provided for each

pressure controlled Bedroom, Play/Dining Room and Contingency Room by means of appropriate PVC Tubing. Each of these Air Pressure Monitoring devices will be interfaced with individual LCD Pressure Display Units (with stainless steel face plates) which will be recessed locally into the walls of the adjacent Corridors. All Air Pressure Monitoring Devices will be located in the an easily accessible part of the adjacent Corridor ceiling void. All Air pressure Monitoring Devices will be interfaced with a new Stainless Steel Nurse's Station Control Panel via appropriate Modbus Tap units. The new Nurse's Station Control Panel will be provided with a facia mounted Colour HMI Display screen, with a minimum size of 175mm. A new Data Logger Unit will be provided as part of this Contract designed to accurately monitor all Pressure Differentials, Room Pressures, etc at set time intervals which must meet the specific operating parameters set by the client, which will generally be in line with the present provision for the Ward 2A BMT, however proportionally uprated to cater for the increased number of rooms served within the new upgraded Ward 2A HOTCT area, in terms of the ability and capacity to record a set amount of Historical Data by the Logger Unit installed within the new Nurse's Control Panel located at the Ward 2A Nurse's station. The new Data Logger will be capable of downloading the historical data in a form that can be readily printed out on standard A4 sheets in an easy to read format for review by Validation and other technical personnel.

The specialist Controls Contractor will be responsible for the final Testing and Commissioning of all Pressure Monitoring Systems, together with the setting to work of the complete new Pressure Monitoring System prior to the client Validation Process.

NURSE'S STATION CONTROL PANEL

- 1 Stainless Steel Surface Mounted Control Panel incorporating LCD display Unit on Facia plate. Similar to Existing Unit presently located at the Ward 2A Nurse's Station c/w with the following:-
- 1 Data Logger Unit for Room Pressures and to provide visual and audible indication of alarm conditions, with mute facility.

1	Main Ventilation Plant On Light
1	Main Ventilation Plant Off Light
1	Common Fault Light
19	Room Air Pressure Monitoring Devices and 6mm O.D Colour Tubing)
38	Ceiling mounted Air Sensors/Probes (connected to above Tubing)

NURSE'S STATION CONTROL PANEL HMI INTERFACE

19	Room Air Pressure Monitoring Devices
19	Room Alarm
2	Ventilation Plant Status

LOCAL ROOM AIR PRESSURE DISPLAY UNITS

19	Wall Mounted Pressure Digital Display Units
19	Pressure Sensor (for differential Pressure)
17	Bedrooms
1	Play/Dining Area
1	Contingency Area

BEDROOM, ETC ROOM RE-HEATERS (LTHW)

20	Heating Control Valves (15mm dia)
20	Room Temperature Sensors
20	Temperature Set Point Adjusters
20	Duct Low Limit

MISCELLANEOUS

19	Gas Tight Room Motorised Isolation Dampers
19	Local manual Open/Closed switch for above Isolation Damper (this Damper will also be capable of being operated from the BMS)

GENERAL SMALL POWER WIRING

The specialist Controls Contractor will allow for providing all necessary Small Power wiring installations required to operate or otherwise serve field mounted equipment such as Outstation Units, Pressure Monitoring Devices, Control Valves, Dampers, Actuators, Remote Display Units, Nurses Control Panel (to also have 48 hour battery back-up provision), etc. It is envisaged that these supplies will be connected to the local KNX infrastructure services as required.

EQUIPOTENTIAL BONDING

Carry out all necessary equipotential bonding to current IET regulations, including all equipotential bonding of metal works and containment systems to AHU, ductwork etc.

COMMUNICATIONS NETWORK

CONTROL PANEL

Supply and erect a wall mounting enclosure suitably sized to accommodate the following:-

- 1 Communications Network Controller
- 1 230/34 Volt Transformer
- 1 Socket Outlet – Service Engineer Equipment
- 3 SP MCB's

All the above to be prewired and labelled as per AHU control panel specification.

ELECTRICAL INSTALLATION

Carry out the installation of the BACnet communications network using an LSF insulated multi-core screened cable interconnecting each of the proposed AHU and ancillary Control Panels housing the BMS controllers to the network controller. The cables to be run on a suitable containment system. An IT data point adjacent to the communications network control panel is to be provided by others.

GRAPHICS

Create and install onto the client's existing BACnet Operators Workstation (B-OWS) colour graphics and user pages giving dynamic information and status of the proposed plant and equipment. Alarms and calendars to be set up in conjunction with client's representatives. All graphics, calendars and alarms are to be created to match those that currently exist for similar plant. The client has a confirmatory document which must be adhered to when graphics are to be installed.

SERVICES

Provide the following services.

- **ENGINEERING**
Provide all working and As Fitted Drawings including Operating & Maintenance Documentation.
- **COMMISSIONING**
Upon completion of the control installation and associated electrical works, carry out a full commissioning of the system.
- **DEMONSTRATION**
Upon completion of the commissioning, carry out a full demonstration of the plant to the client's personnel.

STRIP OUT WORKS**WIRING & CONTAINMENT SYSTEMS**

Identify, make safe then strip out all Power and Controls wiring and associated containment systems (where they do not support other services) and other existing redundant equipment which is effectively being replaced by the new Power and Controls Systems as part of these works. Any controls equipment being made redundant that is connected to the existing BMS/Controls system should be removed from the central supervisory terminal graphics in such a way as to prevent spurious alarms. Upon completion of the stripping out of all necessary cables, containment systems, controls equipment, control panels, switchgear, etc., the Contractor will arrange for all materials to be removed from site and disposed of in a responsible manner.

395.000 THERMAL INSULATION**395.010 GENERAL**

Thermal insulation will be applied to the following:

1. All new Fresh Air/Supply Air ventilation ductwork from external louvres up to the new Ward 2A HOTCT Supply AHUs and thereafter from the Supply AHUs to the various end points of the Supply Ventilation ductwork systems, as generally indicated on the Tender Drawings. All Exhaust/Extract Air from the Ward 2A HOTCT Extract AHUs to the various end points of the Extract Ventilation ductwork systems and from the Extract AHUs to the Penthouse Exhaust Terminal as generally indicated on the Tender Drawings. All thermal insulation on the Supply and Extract Ventilation Ductwork systems will be vapour sealed, insulation systems will all have protective aluminium clad over the vapour seal, within Plantroom areas.
2. All new Domestic Water Services pipework, line fittings, etc, that are located within ceiling/floor/wall voids and other areas covered by SHTM 04-01. All thermal insulation on Domestic Mains Water Services and Domestic Cold Water Services pipework will be vapour sealed. Thermal Insulation will be provided with protective aluminium cladding, over the vapour seal, where this is provided.
3. All new LTHW Heating Services pipework, line fittings, etc. will be fully insulated, with Velcro jackets over valves.
4. All new Chilled Water Services pipework, line fittings, etc. All thermal insulation on Chilled Water pipework will be vapour sealed. Velcro jackets will be fitted over valves. Insulation will all have protective aluminium cladding over the vapour seal.
5. Insulation covering ventilation ductwork, domestic water services heating and chilled water pipework will have a suitable low conductivity value, to ensure that there are no problematic issues accommodating it within the space available.

Thermal insulation on pipework and ductwork within Plantroom areas will be covered with aluminium sheet, in accordance with the specification.

All other thermal insulation will be covered with aluminium foil covering in accordance with the specification.

1.1.1 Project Schedule of Insulating Materials and Finishes

<u>Code</u>	<u>Insulating Materials</u>
1.	Calcium Silicate sections or slabs.
2.	Glass mineral wool pipe sections in 1.2m length with self- seal overlap and factory applied aluminium foil jacket.
3.	Glass mineral wool rigid slabs with factory applied aluminium foil facing or flexible mattress with factory applied aluminium.
4.	Phenolic Foam pipe sections with factory applied aluminium foil jacket.
5.	Phenolic Foam laminate with factory applied aluminium foil facing.

<u>Code</u>	<u>Insulating Materials</u>
A	Factory applied reinforced aluminium foil.
B	Hammerclad Aluminium Cladding.
C	Isogenapak PVC cladding. Isogenpac (Internal use only)
D	Ventureclad External jacketing system.
E	Fibaroll FRP external cladding system

Selection of Insulation & Facings (x denotes suitable alternatives).

All mineral wool and Phenolic foam products to be supplied with factory applied aluminium foil facings.

Preferences to be indicated (x) by specifier for particular projects

1.1.2 Insulation Thickness Tables

In accordance with BS 5422 : 2001

Thickness shown in the tables are based on manufacturer's typical declared thermal conductivity values at the appropriate mean temperature of insulation as follows:-

Insulating material	Mean temperature of insulation (°C)				
	0	+10	+50	+75	+100
	Thermal conductivity (W/.K)				
Phenolic foam (PF)	0.021	0.021	0.023	0.025	*
Glass mineral wool (WM)	0.032	0.032	0.037	0.040	0.044
Nitrile rubber (NR)	0.035	0.037	0.040	0.043	*
Calcium silicate (CS)	*	*	0.050	0.053	0.055

* Not recommended for use at these mean temperatures where.

Mean temperature of insulation = Hot face temperature + Cold face temperature

1.1.2.1 Table 1

Thickness of insulation for chilled and cold water supplies to prevent condensation on a low emissivity outer finish (e.g. Bright Class O Foil) in an ambient still air temperature of 25°C and relative humidity of 80%. (BS 5422: 2001 – Table 8).

		Temperature of Water (°C)					
Steel pipe size (mm)		+10		+5		0

88,9	80,8	2 (15)	4 (20)	3 (15)	6 (20)

Note:

Thicknesses given are minimum calculated specifically against the criteria noted in the table. Adopting these thicknesses may not satisfy other design requirements. Thicknesses shown in brackets are nearest standard thicknesses normally available from manufacturers.

Some of the insulation thicknesses calculated are too large to be applied in practice but are included to highlight the difficulty in protecting small diameter pipes against freezing under extreme conditions. In these cases, to provide the appropriate level of frost protection to certain sizes of pipes, it may be necessary to provide additional heat to the system, for example by controlled periodic circulation of the water or by heat tracing.

Thickness calculations ignore the specific heat capacity and surface resistance of the insulation in order to allow for a common situation where the temperature of the insulation is lower than the initial temperature of the water.

Assumed densities and specific heat capacities of water and pipe materials are:-

Water: 1000 kg/m³ and 4200 J/kg.K

Steel: 7840 kg/m³ and 455 J/kg.K

Copper: 8900 kg/m³ and 390 J/kg.K

1.1.3 Specialist Insulation Contractor

Include for all thermal insulation to be carried out by a Specialist Thermal Insulation Contractor.

396.000 SUPPORTS FOR PLANT, EQUIPMENT, ETC.

396.010 GENERAL

The Mechanical Services Contractor will allow for providing all necessary Secondary Support Steelwork necessary for supporting the Supply and Extract Air Handling Units, Extract Fans Sound Attenuators, Ventilation Ductwork, Heating Services/Chilled Water Services/Domestic Water Services/Soil & Rainwater Drainage/Sprinkler/Medical Gas/Pneumatic Tube System pipework, Containment, Controls Equipment, Control Panels, etc.

Where necessary these supports will be structurally checked by the Client's Structural Engineer on behalf of the client, for stability and general soundness.

The Mechanical Services Contractor will be responsible for providing all appropriate technical details of the plant and equipment concerned to properly assist the Structural Engineer and allow them to make a proper value judgement on the likely acceptability or otherwise of the Mechanical Services Contractor's proposals. The Mechanical Services Contractor will thereafter take full cognisance of the Structural Engineers comments and amend the proposals accordingly, where required/advised.

397.000 O&M RECORD INFORMATION, CLIENT TRAINING DEMONSTRATIONS

Following completion and prior to handover the Sub-Contractor shall demonstrate to the user or his appointed representative, the satisfactory operation of all plant, equipment and controls associated with this project.

The demonstration shall be thorough and shall include demonstration by specialist manufacturers where necessary and the automatic controls specialist. Following satisfactory demonstration of the systems, they shall be handed over to the Employer for Client acceptance.

The Sub-Contractor shall on Practical Completion of the works, provide 2 sets of binder style paper Record Drawings and Operating and Maintenance Instructions for all systems and components provided within the Electrical Services Contract Work with 1 No. copy of the Operating and Maintenance Manuals shall be on CD/DVD in an electronic format (PDF) within each binder style paper manual. Manuals shall be in the format as detailed within an in accordance with BSRIA BG01/07

Record Drawings

Record drawings of the contract works generally shall be provided at a scale to match the design drawings except for the site services layouts which may be produced at a scale no smaller than the tender drawings and plant rooms which must be produced at a scale of 1:50.

During the course of the contract the Sub-Contractor shall keep on site a set of the contract drawings which shall be updated between the contract drawings and the actual installation.

The Record Drawings shall show the complete installation including, the sizes and runs of all conduit and containment, and the precise location of all services which may be buried in the structure or laid solid in the ground.

The position and depth of all underground services shall be clearly indicated. Services buried with a thermal or other protective envelope shall be clearly described.

Operating and Maintenance Instructions

Operating and Maintenance Instructions for the Electrical, Mechanical and Plumbing Contract Works shall comprise full details of all installations and equipment provided by the Sub-Contractor.

The detailed requirements of the Operating and Maintenance Instructions are as described generally below:-

General Technical Description:

This section shall contain, for each service, information on where incoming services enter buildings, details and locations of main plant and equipment etc., an outline of the type of system employed, its component parts, the system controls and the principles of operation.

Operating Instructions:

This section shall contain for each service the item of equipment, details of start up procedures, shut down procedure, isolation procedures, procedures to be followed on fault indication and emergency shut down and/or isolation procedures.

Inspection and Maintenance Instructions

This section shall contain, in outline only, the maintenance requirement for all maintainable items of plant and equipment.

Emergency Procedures:

Instructions shall be included for action required for such circumstances as:-

Fire

General failure of the electrical system

Recommended action on plant/equipment malfunction

Information shall also be included on call out procedures, first aid and electrocution.

Manufacturer's Literature:-

This section shall contain all manufacturers' literature, including Operating and Maintenance information, together with an index of contents listing the equipment item and manufacturer's name, address and telephone number.

Recommended Spares:

This section shall contain, for each equipment item, a list of manufacturer's recommended spares including appropriate reference numbers.

Record Drawings:-

This section shall contain a complete index of Record Drawings as provided indicating the Drawing No., area of the Building and Title.

Commissioning Record Sheets:

This section shall contain copies of all commissioning record sheets with an appropriate index.

Test Certificate and Insurance Inspection Sheets:

This section shall contain copies of all test certificates and insurance inspection sheets together with an appropriate index.

A draft copy of the Operating and Maintenance Instructions shall be submitted to the Employer for approval and, following receipt of such approval, three sets of Operating and Maintenance Instructions, in substantial hard backed binders, shall be provided.

R - DISPOSAL SYSTEMS

R10 RAINWATER PIPEWORK SYSTEMS

PART 1 SYSTEM OBJECTIVES

100.010 PERFORMANCE OBJECTIVES:

- Alterations to existing systems to suit new installations as required and detailed on the (52) Series Drawings

100.011 PERFORMANCE OBJECTIVES:

- The purpose of this specification is that the rainwater pipework / gutter systems and equipment provided in compliance with it, will deliver the whole hospital engineering design philosophies and be compliant with all Department of Health (NHS Estates) documentation including, but not limited to HTM's and HBN's pertinent to the nature of the project.

100.020 DESIGN PARAMETERS:

- Relevant parts of BS EN 12056
- BS 8490 for siphonic roof drainage systems.
- Current Building Regulations Technical Guidance Documents and requirements of the Local Authority

PART 2 SELECTION SCHEDULES FOR REFERENCE SPECIFICATIONS

210.000 PIPELINES AND PIPEWORK

210.010 GENERAL:

- Comply with work section general clauses below
- Fire stopping
 - All components forming the seal system, to be from the same manufacturer
 - Comply with BS 9999, relevant approved technical guidance to Building Regulations and BESA Technical Bulletin TB/032
 - Provide proprietary penetration seal system. All products used, to have third party product certification by a scheme accredited by UKAS.
 - Type
 - Stone mineral wool, soft seal type lamella strip with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. For use in all applications including where movement of services needs to be accommodated. Tested and assessed to BS EN 1366-3 and BS EN 1366-4 and classified to BS EN 13501-2.
 - Stone mineral wool ablative coated batt seal with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. Tested and assessed to BS EN 1366-3.
 - Services expansion and contraction details
 - All services passing through apertures in masonry walls/concrete floors or drywall partitions/systems.
 - Fire resistance
 - 2 hrs.
- Only use UKAS accredited, third party installer certified specialist contractors. The specialists should

be ASFP members and their certification must cover the passive fire protection element they are installing.

- Install all fire stopping systems in accordance with the manufacturer's written instructions and the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
- Support centres for services passing through penetration seals serving fire barriers to be the same as those covered by the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
- Install and inspect fire stopping systems in accordance with Building Regulations Approved Document B, ASFP Code of Practice TGD 17 and the general best practice guidance given in the ASFP On-site guide to installing fire-stopping.

210.040 CAST/DUCTILE IRON PIPES AND FITTINGS:

- Manufacturer To Match Existing - Ensign etc.
- Fluid conveyed Rain Water
- Cast iron/ductile iron pipes and fittings to BS 416-1
 - Spigot and socket - reference Y10.2350A
- Cast iron/ductile iron pipes to BS 437
 - For flexible joints - reference Y10.2370A
- Cast iron/ductile iron fittings to BS 437
 - For flexible joints - reference Y10.2380A
- Cast iron pipes and fittings to BS EN 877
 - Red epoxy finish - reference Y10.2390A
 - Grey epoxy finish - reference Y10.2390B
- Ductile iron pipes to BS EN 545
 - Flanged joints - reference Y10.2410A
 - Spigot and socket joints - reference Y10.2410B
- Ductile iron pipes for water applications to BS ISO 2531
 - Flanged joints - reference Y10.2425A
 - Spigot and socket joints - reference Y10.2425B
- Preinsulated ductile iron pipes, fittings, accessories and joints to BS ISO 9349
 - Application
 - Waste water / drainage
 - Location
 - Above ground
 - Joints
 - Flanged
 - Spigot and socket
 - Flexible joints for water applications to BS ISO 2531
 - Flexible joints for sewerage applications to ISO 7186
- Jointing materials
 - Flanges to BS EN 1092-2.
 - Flanges BS EN 1092-2 PN
 - Cast iron flanges - reference Y10.3010C
 - Flange jointing rings
 - For cast iron - reference Y10.3020C
 - Use push-fit joints for cast iron pipe.
 - Couplings for cast iron pipes to BS EN 877
 - Stainless steel - reference Y10.3105A
 - Red ductile iron - reference Y10.3105B
 - Grey ductile iron - reference Y10.3105C
 - Black ductile iron - reference Y10.3105D
 - Spigot/socket caulked joints

- Reference Y10.3110A
- Use push-in self anchor joints for ductile iron pipes.
- Flexible couplings, sleeve type
 - For ductile iron pipework to BS EN 545, BS EN 598, BS EN 969 - reference Y10.3170A
- Flexible flange adapters, sleeve type
 - For ductile iron pipework to BS EN 545, BS EN 598, BS EN 969 - reference Y10.3180A
- Internal polyurethane lining
 - Provide internal polyurethane linings for ductile iron pipework in accordance with BS EN 15655.

210.050 PLASTICS PIPES AND FITTINGS:

- Fluid conveyed Rain Water
- Plastics piping systems for water supply
 - Reference Y10.2455A - pipes to
 - BS EN ISO 1452-1
 - BS EN ISO 1452-2
 - BS EN ISO 1452-5
 - Reference Y10.2475A - fittings to
 - BS EN ISO 1452-1
 - BS EN ISO 1452-3
- BS EN ISO 1452-5
- Plastic piping systems, buried and above ground for water and other fluids (not potable water)
 - Pipes, fittings and joints to BS EN 15014 - reference Y10.2442
- PVC-U fittings to BS 4514
- Reference Y10.2490A
 - PP Pipes to BS EN 1451-1 and BS EN 15012 - reference Y10.2545A
 - Fittings to BS EN 1451-1 and BS EN 15012 - reference Y10.2555A
 - Solid wall PVC-U pipes to BS EN 1329-1 and BS 4514 - reference Y10.2580A
 - Structured-wall PVC-U pipes to BS EN 1453-1 - reference Y10.2580F
 - ABS pipes to BS EN 1455-1 - reference Y10.2580B
 - PE pipes to BS EN 1519-1 - reference Y10.2580C
 - SAN + PVC pipes to BS EN 1565-1 - reference Y10.2580D
 - PVC-C pipes to BS EN 1566-1 - reference Y10.2580E
 - GRP systems based on unsaturated polyester (UP) resin to BS ISO 10467 or BS EN 14364
 - PVC-U fittings to BS EN 1329-1 and BS 4514 - reference Y10.2585A
 - ABS fittings to BS EN 1455-1 - reference Y10.2585B
 - PE fittings to BS EN 1519-1 - reference Y10.2585C
 - SAN + PVC fittings to BS EN 1565-1 - reference Y10.2585D
 - PVC-C fittings to BS EN 1566-1 - reference Y10.2585E
 - Structured wall PVC-U pipes to BS EN 1453 - reference Y10.2495A
- Plastic rainwater piping systems comprising pipes, fittings and brackets for above ground external use to BS EN 12200-1
 - Pipe material
 - Solid wall PVC-U.
 - Pipe type / details
 - Circular

210.070 PIPEWORK ACCESSORIES:

- Wall, floor and ceiling masking plates
 - Chromium plated - reference Y10.3190A.
 - Plastic - reference Y10.3190B
- Pipe rings and clips

- Pipework support - reference Y10.4210

210.080 GENERAL WORKMANSHIP:

- Appearance - reference Y10.4010
- Spacing - reference Y10.4020
- Gradients - reference Y10.4030
- Air venting requirements
 - Air bottles - reference Y10.4040A
 - Automatic air vents - reference Y10.4040B
- Drain requirements - reference Y10.4050
- Expansion and contraction - reference Y10.4060
- Pipe fittings
 - Bends/swept tees - reference Y10.4070A
 - Elbows/square tees - reference Y10.4070B
- Pipes through walls and floors - reference Y10.4110
- Protect pipework penetrating fire separating elements in accordance with, Building Regulations, BS 9999 and BESA Technical Bulletin TB/032.
- Pipe sleeves
 - Reference Y10.4120A
 - Insulation carried through - reference Y10.4120B
- Pipe through fire barriers - reference Y10.4125
 - Type
 - Proprietary sleeves
 - Ablative coated batt type
 - Fire resistance
 - 2 hours
 - hrs
- Connect to equipment.
- Use distribution headers.
- Temporary plugs, caps and flanges
 - Reference Y10.4150A.
- Flanged joints general - reference Y10.4160
- Dissimilar metals - reference Y10.4170
- Pipe rings and clips - reference Y10.4180
 - Anchors - reference Y10.4190
- Pipe supports - reference Y10.4205
 - Comply with the manufacturers' installation recommendations for the following proprietary pipe systems:
- Support spacing
 - Tables for steel, copper, iron, PVC and ABS pipes - reference Y10.4220
 - For the following proprietary pipe systems comply with the manufacturers' installation recommendations:
 - Plastic pipe systems.
- Maintenance and renewal - reference Y10.4240
- Non-ferrous components - thoroughly clean and degrease.
- Pipe collars (closers) for plastic pipes where they pass through fire resistant walls and floors.
 - Type
 - Stainless steel collar with fixing brackets with intumescent liner.
 - Pre-assembled wrap for casing within concrete floor or masonry wall.
 - Fire resistance
 - 2 hrs
 - Installation to be in accordance with the manufacturer's instructions and grouted/sealed using the

manufacturer's proprietary compound/sealant.

- Standards
 - Test to BS EN 1366-3 and BS EN 1363-1.
- Test to BS 476-20.

210.110 WORKMANSHIP, CAST/DUCTILE IRON:

- Flanged joints - reference Y10.7010
- Caulked joints - reference Y10.7020
- Flexible joints - reference Y10.7030

210.120 WORKMANSHIP, PLASTIC PIPES:

- Installation of thermoplastic piping for soil and waste discharge inside buildings and buried in ground within the building - reference Y10.8005
- Installation of thermoplastic polybutylene and cross linked polyethylene piping for hot and cold water systems and heating systems - reference Y10.8006
- Solvent welded joints, PVC - reference Y10.8010
- Fusion joints, PE - reference Y10.8020
- Mechanical fittings, PE - reference Y10.8030
- Anchors, PVC - reference Y10.8040
- Jointing polybutylene pipes and fittings - reference Y10.8050
- Plastic pipes and fittings with secondary containment and fittings for underground fuel oil systems - reference Y10.8070.

254.000 IDENTIFICATION - MECHANICAL

254.010 GENERAL:

- Comply with work section general clauses below
 - Requirements - reference Y54.1010
 - New systems - reference Y54.1020
 - Existing systems - reference Y54.1030
 - Colours - reference Y54.1040
 - Performance and durability - reference Y54.1045
- Provide identification - mechanical as specified in work section

254.020 PIPEWORK IDENTIFICATION:

- Reference Y54.2010

254.045 GRAPHICAL SYMBOLS FOR USE ON EQUIPMENT IN ACCORDANCE WITH BS EN 80416:

- Reference Y54.2035

254.070 LABORATORY OUTLETS:

- Type
- Application

254.100 DANGER AND WARNING NOTICES:

- Reference Y54.2090

254.110 SYSTEM IDENTIFICATION INSTALLATION CHARTS:

- Perspex sheet glazing with frame - reference Y54.2100A

290.000 FIXING TO BUILDING FABRIC

290.010 GENERAL:

- Comply with work section general clauses below
 - Preparation - reference Y90.1010
 - Manufacturer's drawings - reference Y90.1020
 - Fixings - reference Y90.1030
 - Loading details - reference Y90.1040
 - Building-in by others - reference Y90.1050
 - Size of fixing - reference Y90.1060
- Greasing of fixings - reference Y90.1070

290.020 FIXINGS:

- Standards - reference Y90.2010
- Plugs - reference Y90.2020
- Screws - reference Y90.2030
- Non-penetrative support systems - reference Y90.2080
 - Manufacturer and reference
 - Or approved equivalent.

290.030 WORKMANSHIP:

- Drilling - reference Y90.3010
- Fixing to timber rails - reference Y90.3050
- Fixing to hollow stud/tile/block wall
 - Reference Y90.3060A
- Fixing to concrete, brickwork or blockwork
 - Reference Y90.3070A
- Fixing to metalwork
 - Reference Y90.3080A
- Fixing to structural steelwork and concrete structures
 - Reference Y90.3090A
- Non-penetrative support systems for roof mounted equipment - reference Y90.3100#

291.000 OFF-SITE PAINTING AND ANTI-CORROSION TREATMENT

291.010 GENERAL

- Comply with work section general clauses below
 - General requirements - reference Y91.1010
- Damaged finishes - reference Y91.1020

291.020 PAINT MATERIALS:

- Paint materials
 - Reference Y91.2010A

- Paint quality - reference Y91.2020

291.030 WORKMANSHIP

- Weather and other conditions - reference Y91.3020
- Cleaning and preparing for painting
 - Steel surfaces - reference Y91.3030A
 - Surfaces - reference Y91.3030B
 - Reference Y91.3030#
- Application off-site - reference Y91.3040
- Application - reference Y91.3050
- Cold galvanizing - reference Y91.3060
- Protection of bright machine parts - reference Y91.3070
- Special protective finishes

PART 3 SPECIFICATION CLAUSES SPECIFIC TO R10

300.000 GENERAL / PRODUCT / MATERIALS

300.005 DRAINAGE SPECIALIST:

- On design and build projects engage a drainage specialist to develop the design, install, commission and set to work a roof drainage system operating under gravity inside the building in accordance with BS EN 12056-3

BS APPENDIX

BS 416-1:2009

Discharge and ventilating pipes and fittings, sand-cast or spun in cast iron. Part 1 Specification for spigot and socket systems

BS 437:2008

Specification for cast iron drain pipes, fittings and their joints for socketed and socketless systems

BS 476-7:1997

Fire tests on building materials and structures. Part 7 Method of test to determine the classification of the surface spread of flame of products

BS 476-20:1987

Fire tests on building materials and structures. Part 20 Method for determination of the fire resistance of elements of construction (general principles)

BS 4514:2001

Unplasticized PVC soil and ventilating pipes of 82.4mm minimum mean outside diameter, and fittings and accessories of 82.4mm and of other sizes. Specification

BS 8490:2007

Guide to siphonic roof drainage systems

BS 9999:2017

Fire safety in the design, management and use of buildings. Code of practice

BS EN 545:2010

Ductile iron pipes, fittings, accessories and their joints for water pipelines. Requirements and test methods

BS EN 598:2007+A1:2009

Ductile iron pipes, fittings, accessories and their joints for sewerage applications. Requirements and test methods

BS EN 877:1999+A1:2006

Cast iron pipes and fittings, their joints and accessories for the evacuation of water from buildings. Requirements, test methods and quality assurance

BS EN 969:2009

Specification for ductile iron pipes, fittings, accessories and their joints for gas pipelines. Requirements and test methods

BS EN 1092-1:2018

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 1 steel flanges

BS EN 1092-2:1997

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 2 cast iron flanges

BS EN 1329-1:2014+A1:2018

Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Unplasticized poly(vinyl chloride) (PVC-U). Specifications for pipes, fittings and the systems

BS EN 1363-1:2012

Fire resistance tests. General requirements

BS EN 1366-3:2009

Fire resistance tests for service installations. Penetration seals

BS EN 1366-4:2006+A1:2010

Fire resistance tests for service installations. Linear joint seals

BS EN 1451-1:2017

Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Part 1 Polypropylene (PP). Specifications for pipes, fittings and the system

BS EN 1453-1:2017

Plastics piping systems with structured-wall pipes for soil and waste discharge (low and high temperature) inside buildings. Unplasticized poly (vinyl chloride) (PVC-U). Part 1 Specifications for pipes and the system

BS EN 1453-1:2017

Plastics piping systems with structured-wall pipes for soil and waste discharge (low and high temperature) inside buildings. Unplasticized poly (vinyl chloride) (PVC-U). Part 1 Specifications for pipes and the system

BS EN 1455-1:2000

Plastics piping systems for soil and waste (low and high temperature) within the building structure. Acrylonitrile-butadiene-styrene (ABS). Part 1 Specifications for pipes, fittings and the system

BS EN 1519-1:2000

Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Polyethylene (PE). Part 1 Specifications for pipes, fittings and the system

BS EN 1565-1:2000

Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Styrene copolymer blends (SAN + PVC). Part 1 Specifications for pipes, fittings and the system

BS EN 1566-1:2000

Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Chlorinated poly(vinyl chloride) (PVC-C). Part 1 Specification for pipes, fittings and the system

BS EN 12056-1:2000

Gravity drainage systems inside buildings. Part 1 General and performance requirements

BS EN 12056-2:2000

Gravity drainage systems inside buildings. Part 2 Sanitary pipework, layout and calculation

BS EN 12056-3:2000

Gravity drainage systems inside buildings. Part 3 Roof drainage, layout and calculation

BS EN 12056-4:2000

Gravity drainage systems inside buildings. Part 4 Wastewater lifting plants. Layout and calculation

BS EN 12056-5:2000

Gravity drainage systems inside buildings. Part 5 Installation and testing, instructions for operation, maintenance and use

BS EN 12200-1:2016

Plastics rainwater piping systems for above ground external use. Unplasticized poly(vinyl

chloride)(PVC-U). Specifications for pipes, fittings and the system

BS EN 13501-2:2016

Fire classification of construction products and building elements. Classification using data from fire resistance tests, excluding ventilation services

BS EN 14364:2013

Plastic piping systems for drainage and sewerage with or without pressure. Glass reinforced thermosetting plastics (GRP) based on unsaturated polyester resin (UP). Specifications for pipes, fittings and joints

BS EN 15012:2007

Plastics piping systems. Soil and waste discharge systems within the building structure. Performance characteristics for pipes, fittings and their joints

BS EN 15014:2007

Plastics piping systems. Buried and above ground systems for water and other fluids under pressure. Performance characteristics for pipes, fittings and their joints

BS EN 15655:2009

Ductile iron pipes, fittings and accessories. Internal polyurethane lining for pipes and fittings. Requirements and test methods

BS EN 80416-1:2009

Basic principles for graphical symbols for use on equipment. Part 1 Creation of symbol originals

BS EN 80416-2:2001

Basic principles for graphical symbols for use on equipment. Part 2 Form and use of arrows

BS EN 80416-3:2002+A1:2011

Basic principles for graphical symbols for use on equipment. Part 3 Guidelines for the application of graphical symbols

BS EN ISO 1452-1:2009

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 1 General

BS EN ISO 1452-2:2009

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 2 Pipes

BS EN ISO 1452-3:2010

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 3 Fittings

BS EN ISO 1452-5:2009

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 5 Fitness for purpose of the system

BS ISO 2531:2009

Ductile iron pipes, fittings, accessories and their joints for water applications

BS ISO 9349:2017

Ductile iron pipes, fittings, accessories and their joints. Thermal preinsulated products

BS ISO 10467:2018

Plastics piping systems for pressure and non-pressure drainage and sewerage. Glass-reinforced thermosetting plastics (GRP) systems based on unsaturated polyester (UP) resin

ISO 7186:2011

Ductile iron products for sewerage applications

R11 FOUL DRAINAGE ABOVE GROUND

PART 1 SYSTEM OBJECTIVES

100.010 PERFORMANCE OBJECTIVES:

- Alterations to the existing above ground drainage system, generally as detailed on the (52) Series Drawings

100.011 PERFORMANCE OBJECTIVES:

- The purpose of this specification is that the foul drainage above ground systems and equipment provided in compliance with it, will deliver the whole hospital engineering design philosophies and be compliant with all Department of Health (NHS Estates) documentation including, but not limited to HTM's and HBN's pertinent to the nature of the project.

100.020 DESIGN PARAMETERS:

- Relevant parts of BS EN 12056
- Current Building Regulations Technical Guidance Documents and requirements of the Local Authority

100.040 CONTROL REQUIREMENTS:

- Isolations and Liaison with NHS Estates along with wards the will be effected by the isolations will be required by the contractor on a local site level

100.060 SYSTEM DRAWINGS:

- Reference (52) Series Drawings

PART 2 SELECTION SCHEDULES FOR REFERENCE SPECIFICATIONS

210.000 PIPELINES AND PIPEWORK

210.010 GENERAL:

- Comply with work section general clauses below
 - prefabricated pipework - reference Y10.1010
- Fire stopping
 - All components forming the seal system, to be from the same manufacturer
 - Comply with BS 9999, relevant approved technical guidance to Building Regulations and BESA Technical Bulletin TB/032
 - Provide proprietary penetration seal system. All products used, to have third party product certification by a scheme accredited by UKAS.
 - Type
 - Stone mineral wool, soft seal type lamella strip with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. For use in all applications including where movement of services needs to be accommodated. Tested and assessed to BS EN 1366-3 and BS EN 1366-4 and classified to BS EN 13501-2.
 - Stone mineral wool ablative coated batt seal with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. Tested and assessed to BS EN 1366-3.
 - All services passing through apertures in masonry walls/concrete floors or drywall

partitions/systems.

- Fire resistance
 - 2 hrs.
- Only use UKAS accredited, third party installer certified specialist contractors. The specialists should be ASFP members and their certification must cover the passive fire protection element they are installing.
- Install all fire stopping systems in accordance with the manufacturer's written instructions and the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
- Support centres for services passing through penetration seals serving fire barriers to be the same as those covered by the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
- Install and inspect fire stopping systems in accordance with Building Regulations Approved Document B, ASFP Code of Practice TGD 17 and the general best practice guidance given in the ASFP On-site guide to installing fire-stopping.

210.040 CAST/DUCTILE IRON PIPES AND FITTINGS:

- Type In line with existing systems, Ensign etc.
- Application Above ground drairage systems.
- Manufacturer Ensign or similar to match the existing systems installed
 - Or approved equivalent
- Cast iron/ductile iron pipes and fittings to BS 416-1
 - Spigot and socket - reference Y10.2350A
- Cast iron/ductile iron pipes to BS 437
 - For flexible joints - reference Y10.2370A
- Cast iron/ductile iron fittings to BS 437
 - For flexible joints - reference Y10.2380A
- Cast iron pipes and fittings to BS EN 877
 - Red epoxy finish - reference Y10.2390A
 - Grey epoxy finish - reference Y10.2390B
- Ductile iron pipes to BS EN 545
 - Flanged joints - reference Y10.2410A
 - Spigot and socket joints - reference Y10.2410B
- Ductile iron pipes for water applications to BS ISO 2531
 - Flanged joints - reference Y10.2425A
 - Spigot and socket joints - reference Y10.2425B
- Jointing materials
 - Flanges to BS EN 1092-2.
 - Flanges BS EN 1092-2 PN
 - Cast iron flanges - reference Y10.3010C
 - Flange jointing rings
 - For cast iron - reference Y10.3020C
 - Use push-fit joints for cast iron pipe.
 - Couplings for cast iron pipes to BS EN 877
 - Stainless steel - reference Y10.3105A
 - Red ductile iron - reference Y10.3105B
 - Grey ductile iron - reference Y10.3105C
 - Black ductile iron - reference Y10.3105D
 - Spigot/socket caulked joints
 - Reference Y10.3110A
 - Use push-in self anchor joints for ductile iron pipes.
 - Flexible couplings, sleeve type
 - For ductile iron pipework to BS EN 545, BS EN 598, BS EN 969 - reference Y10.3170A
 - Flexible flange adapters, sleeve type

- For ductile iron pipework to BS EN 545, BS EN 598, BS EN 969 - reference Y10.3180A
- Internal polyurethane lining
 - Provide internal polyurethane linings for ductile iron pipework in accordance with BS EN 15655.

210.050 PLASTICS PIPES AND FITTINGS:

- Plastics piping systems for water supply
 - Reference Y10.2455A - pipes to
 - BS EN ISO 1452-1
 - BS EN ISO 1452-2
 - BS EN ISO 1452-5
 - Reference Y10.2475A - fittings to
 - BS EN ISO 1452-1
 - BS EN ISO 1452-3
- BS EN ISO 1452-5
- Plastic piping systems, buried and above ground for water and other fluids (not potable water)
 - Pipes, fittings and joints to BS EN 15014 - reference Y10.2442
- PVC-U fittings to BS 4514
 - Reference Y10.2490A
- PVC-O to BS ISO 16422
 - Reference Y10.2491A 12666-1
- Compression fittings for polyethylene
- Reference Y10.2510A systems of PVC-U, PP and PE, to relevant parts of BS EN 13476
 - Pipes and fittings with smooth internal and external surface, Type A, to BS EN 13476-2 - reference Y10.2553A
- Pipes and fittings with smooth internal and profiled external surfaces, Type B, to BS EN 13476-3 - reference Y10.2553B
- Plastics piping systems for soil, waste and rainwater discharge within the building structure
 - PP Pipes to BS EN 1451-1 and BS EN 15012 - reference Y10.2545A
 - Fittings to BS EN 1451-1 and BS EN 15012 - reference Y10.2555A
 - Solid wall PVC-U pipes to BS EN 1329-1 and BS 4514 - reference Y10.2580A
 - Structured-wall PVC-U pipes to BS EN 1453-1 - reference Y10.2580F
 - PVC-U fittings to BS EN 1329-1 and BS 4514 - reference Y10.2585A
 - Structured wall PVC-U pipes to BS EN 1453 - reference Y10.2495A
- Plastic rainwater piping systems comprising pipes, fittings and brackets for above ground external use to BS EN 12200-1
 - Pipe material
 - Solid wall PVC-U.
 - Pipe type / details
- Circular
 - Special materials
- Unplasticised PVC pipes to BS EN 1401-1
- Unplasticised PVC pipe fittings to BS EN 1401-1

210.060 OTHER PIPES AND FITTINGS:

210.070 PIPEWORK ACCESSORIES:

- Wall, floor and ceiling masking plates
 - Chromium plated - reference Y10.3190A.
 - Plastic - reference Y10.3190B
- Pipe rings and clips
- Copper pipework

- Use plastic pipe clips.
- Use brass pipe clips.
- Pipework support - reference Y10.4210

210.080 GENERAL WORKMANSHIP:

- Appearance - reference Y10.4010
- Spacing - reference Y10.4020
- Gradients - reference Y10.4030
- Air venting requirements
 - Air bottles - reference Y10.4040A
 - Automatic air vents - reference Y10.4040B
- Drain requirements - reference Y10.4050
- Expansion and contraction - reference Y10.4060
- Pipe fittings
 - Bends/swept tees - reference Y10.4070A
 - Elbows/square tees - reference Y10.4070B
- Pipes through walls and floors - reference Y10.4110
- Protect pipework penetrating fire separating elements in accordance with, Building Regulations, BS 9999 and BESA Technical Bulletin TB/032.
- Pipe sleeves
 - Reference Y10.4120A
 - Insulation carried through - reference Y10.4120B
- Pipe through fire barriers - reference Y10.4125
 - Type
 - Proprietary sleeves
 - Ablative coated batt type
 - Fire resistance
 - 2 hours
 - hrs
- Connect to equipment.
- Use distribution headers.
- Temporary plugs, caps and flanges
 - Reference Y10.4150A.
- Flanged joints general - reference Y10.4160
- Dissimilar metals - reference Y10.4170
- Pipe rings and clips - reference Y10.4180
 - Anchors - reference Y10.4190
- Pipe supports - reference Y10.4205
 - Comply with the manufacturers' installation recommendations for the following proprietary pipe systems:
 - Plastic pipe systems.
 -
- Support spacing
 - Tables for steel, copper, iron, PVC and ABS pipes - reference Y10.4220
 -
- Isolation and regulation
 - Reference Y10.4230A
- Maintenance and renewal - reference Y10.4240
- Clean by removing cement and clean off all pipework and brackets.
- Non-ferrous components - thoroughly clean and degrease.
- Pipe collars (closers) for plastic pipes where they pass through fire resistant walls and floors.
 - Type

- Stainless steel collar with fixing brackets with intumescent liner.
- Pre-assembled wrap for casing within concrete floor or masonry wall.
- Fire resistance
 - 2 hrs
 - hrs
- Installation to be in accordance with the manufacturer's instructions and grouted/sealed using the manufacturer's proprietary compound/sealant.
- Standards
 - Test to BS EN 1366-3 and BS EN 1363-1.
- Test to BS 476-20.

210.100 WORKMANSHIP, COPPER PIPEWORK:

- Compression joints - reference Y10.6030
- Capillary joints - reference Y10.6040
- Anchors
 - Flanges - reference Y10.6060A
- Saddle clamps - reference Y10.6060B

210.110 WORKMANSHIP, CAST/DUCTILE IRON:

- Flanged joints - reference Y10.7010
- Caulked joints - reference Y10.7020
- Flexible joints - reference Y10.7030

210.120 WORKMANSHIP, PLASTIC PIPES:

- Installation of thermoplastic piping for soil and waste discharge inside buildings and buried in ground within the building - reference Y10.8005
- Installation of thermoplastic polybutylene and cross linked polyethylene piping for hot and cold water systems and heating systems - reference Y10.8006
- Solvent welded joints, PVC - reference Y10.8010
- Fusion joints, PE - reference Y10.8020
- Mechanical fittings, PE - reference Y10.8030
- Anchors, PVC - reference Y10.8040
- Jointing polybutylene pipes and fittings - reference Y10.8050
- Plastic pipes and fittings with secondary containment and fittings for underground fuel oil systems - reference Y10.8070.

211.000 PIPELINE ANCILLARIES

211.080 TEST PLUGS:

- Self sealing test points - reference Y11.2670A
- Valve controlled test points - reference Y11.2670B

211.120 TUNDISHES:

- Copper - reference Y11.2690A
- Mild steel, galvanized - reference Y11.2690B

211.160 LOOSE ITEMS:

- Keys for spindle shank valves - reference Y11.3010A
 - Number
- For drain cocks - reference Y11.3010B
- Number

254.000 IDENTIFICATION - MECHANICAL

254.010 GENERAL:

- Comply with work section general clauses below
 - Requirements - reference Y54.1010
 - New systems - reference Y54.1020
 - Existing systems - reference Y54.1030
 - Colours - reference Y54.1040
 - Performance and durability - reference Y54.1045
- Provide identification - mechanical as specified in work section

254.020 PIPEWORK IDENTIFICATION:

- Reference Y54.2010

254.045 GRAPHICAL SYMBOLS FOR USE ON EQUIPMENT IN ACCORDANCE WITH BS EN 80416:

- Reference Y54.2035

254.100 DANGER AND WARNING NOTICES:

- Reference Y54.2090

254.110 SYSTEM IDENTIFICATION INSTALLATION CHARTS:

- Perspex sheet glazing with frame - reference Y54.2100A

290.000 FIXING TO BUILDING FABRIC

290.010 GENERAL:

- Comply with work section general clauses below
 - Preparation - reference Y90.1010
 - Manufacturer's drawings - reference Y90.1020
 - Fixings - reference Y90.1030
 - Loading details - reference Y90.1040
 - Building-in by others - reference Y90.1050
 - Size of fixing - reference Y90.1060
- Greasing of fixings - reference Y90.1070

290.020 FIXINGS:

- Standards - reference Y90.2010
- Plugs - reference Y90.2020
- Screws - reference Y90.2030

- Non-penetrative support systems - reference Y90.2080

290.030 WORKMANSHIP:

- Drilling - reference Y90.3010
- Fixing to timber rails - reference Y90.3050
- Fixing to hollow stud/tile/block wall
 - Reference Y90.3060A
- Fixing to concrete, brickwork or blockwork
 - Reference Y90.3070A
- Fixing to metalwork
 - Reference Y90.3080A
- Fixing to structural steelwork and concrete structures
 - Reference Y90.3090A
- Non-penetrative support systems for roof mounted equipment - reference Y90.3100#

291.000 OFF-SITE PAINTING AND ANTI-CORROSION TREATMENT

291.010 GENERAL

- Comply with work section general clauses below
 - General requirements - reference Y91.1010
- Damaged finishes - reference Y91.1020

291.020 PAINT MATERIALS:

- Paint materials
 - Reference Y91.2010A
- Paint quality - reference Y91.2020

291.030 WORKMANSHIP

- Weather and other conditions - reference Y91.3020
- Cleaning and preparing for painting
 - Steel surfaces - reference Y91.3030A
 - Surfaces - reference Y91.3030B
 - Reference Y91.3030#
- Application off-site - reference Y91.3040
- Application - reference Y91.3050
- Cold galvanizing - reference Y91.3060
- Protection of bright machine parts - reference Y91.3070

Fire tests on building materials and structures. Part 20 Method for determination of the fire resistance of elements of construction (general principles)

BS 4514:2001

Unplasticized PVC soil and ventilating pipes of 82.4mm minimum mean outside diameter, and fittings and accessories of 82.4mm and of other sizes. Specification

BS 9999:2017

Fire safety in the design, management and use of buildings. Code of practice

BS EN 545:2010

Ductile iron pipes, fittings, accessories and their joints for water pipelines. Requirements and test methods

BS EN 598:2007+A1:2009

Ductile iron pipes, fittings, accessories and their joints for sewerage applications. Requirements and test methods

BS EN 877:1999+A1:2006

Cast iron pipes and fittings, their joints and accessories for the evacuation of water from buildings. Requirements, test methods and quality assurance

BS EN 969:2009

Specification for ductile iron pipes, fittings, accessories and their joints for gas pipelines. Requirements and test methods

BS EN 1092-1:2018

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 1 steel flanges

BS EN 1092-2:1997

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 2 cast iron flanges

BS EN 1092-3:2003

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 3 copper alloy flanges

BS EN 1092-4:2002

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 4

aluminium alloy flanges

BS EN 1329-1:2014+A1:2018

Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Unplasticized poly(vinyl chloride) (PVC-U). Specifications for pipes, fittings and the systems

BS EN 1363-1:2012

Fire resistance tests. General requirements

BS EN 1366-3:2009

Fire resistance tests for service installations. Penetration seals

BS EN 1366-4:2006+A1:2010

Fire resistance tests for service installations. Linear joint seals

BS EN 1401-1:2009

Plastics piping systems for non-pressure underground drainage and sewerage. Unplasticized poly(vinyl chloride) (PVC-U). Part 1 Specifications for pipes, fittings and the system

BS EN 1451-1:2017

Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Part 1 Polypropylene (PP). Specifications for pipes, fittings and the system

BS EN 1453-1:2017

Plastics piping systems with structured-wall pipes for soil and waste discharge (low and high temperature) inside buildings. Unplasticized poly (vinyl chloride) (PVC-U). Part 1 Specifications for pipes and the system

BS EN 1453-1:2017

Plastics piping systems with structured-wall pipes for soil and waste discharge (low and high temperature) inside buildings. Unplasticized poly (vinyl chloride) (PVC-U). Part 1 Specifications for pipes and the system

BS EN 12056-1:2000

Gravity drainage systems inside buildings. Part 1 General and performance requirements

BS EN 12056-2:2000

Gravity drainage systems inside buildings. Part 2 Sanitary pipework, layout and calculation

BS EN 12056-3:2000

Gravity drainage systems inside buildings. Part 3 Roof drainage, layout and calculation

BS EN 12056-4:2000

Gravity drainage systems inside buildings. Part 4 Wastewater lifting plants. Layout and calculation

BS EN 12056-5:2000

Gravity drainage systems inside buildings. Part 5 Installation and testing, instructions for operation, maintenance and use

BS EN 12200-1:2016

Plastics rainwater piping systems for above ground external use. Unplasticized poly(vinyl chloride)(PVC-U). Specifications for pipes, fittings and the system

BS EN 13476-1:2018

Plastics piping systems for non-pressure underground drainage and sewerage. Structured-wall piping systems of unplasticized poly(vinyl chloride) (PVC-U), polypropylene (PP) and polyethylene (PE). Part 1 General requirements and performance characteristics

BS EN 13476-2:2018

Plastics piping systems for non-pressure underground drainage and sewerage. Structured-wall piping systems of unplasticized poly(vinyl chloride) (PVC-U), polypropylene (PP) and polyethylene (PE). Specifications for pipes and fittings with smooth internal and external surface and the system, Type A

BS EN 13476-3:2018

Plastics piping systems for non-pressure underground drainage and sewerage. Structured-wall piping systems of unplasticized poly(vinyl chloride) (PVC-U), polypropylene (PP) and polyethylene (PE). Part 3 Specifications for pipes and fittings with smooth internal and profiled external surface and the system, Type B

BS EN 13501-2:2016

Fire classification of construction products and building elements. Classification using data from fire resistance tests, excluding ventilation services

BS EN 15012:2007

Plastics piping systems. Soil and waste discharge systems within the building structure. Performance characteristics for pipes, fittings and their joints

BS EN 15014:2007

Plastics piping systems. Buried and above ground systems for water and other fluids under pressure. Performance characteristics for pipes, fittings and their joints

BS EN 15655:2009

Ductile iron pipes, fittings and accessories. Internal polyurethane lining for pipes and fittings. Requirements and test methods

BS EN 80416-1:2009

Basic principles for graphical symbols for use on equipment. Part 1 Creation of symbol originals

BS EN 80416-2:2001

Basic principles for graphical symbols for use on equipment. Part 2 Form and use of arrows

BS EN 80416-3:2002+A1:2011

Basic principles for graphical symbols for use on equipment. Part 3 Guidelines for the application of graphical symbols

BS EN ISO 1452-1:2009

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 1 General

BS EN ISO 1452-2:2009

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 2 Pipes

BS EN ISO 1452-3:2010

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 3 Fittings

BS EN ISO 1452-5:2009

Plastics piping systems for water supply and for buried and above-ground drainage and sewerage under pressure. Unplasticized poly(vinyl chloride) (PVC U). Part 5 Fitness for purpose of the system

BS ISO 2531:2009

Ductile iron pipes, fittings, accessories and their joints for water applications

BS ISO 16422:2014

Pipes and joints made of oriented unplasticized poly(vinyl chloride) (PVC-O) for the conveyance of water under pressure. Specifications

S - PIPEWORK and DUCTWORK SYSTEMS

PART 1 SYSTEM OBJECTIVES

100.060 SYSTEM DRAWINGS:

- (53), (55) and (56) Series Drawings

PART 2 SELECTION SCHEDULES FOR REFERENCE SPECIFICATIONS

210.000 PIPELINES AND PIPEWORK

210.010 GENERAL:

- Comply with work section general clauses below
 - prefabricated pipework - reference Y10.1010
 - Supply pre-insulated underground pipeline as schedule reference Pre-insulated Pipework
 - Location As detailed on the drawings
- Fire stopping
 - All components forming the seal system, to be from the same manufacturer
 - Comply with BS 9999, relevant approved technical guidance to Building Regulations and BESA Technical Bulletin TB/032
 - Provide proprietary penetration seal system. All products used, to have third party product certification by a scheme accredited by UKAS.
 - Type
 - Stone mineral wool, soft seal type lamella strip with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. For use in all applications including where movement of services needs to be accommodated. Tested and assessed to BS EN 1366-3 and BS EN 1366-4 and classified to BS EN 13501-2.
 - Stone mineral wool ablative coated batt seal with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. Tested and assessed to BS EN 1366-3.
 - All services passing through apertures in masonry walls/concrete floors or drywall partitions/systems.
 - Fire resistance
 - 2 hrs.
 - Only use UKAS accredited, third party installer certified specialist contractors. The specialists should be ASFP members and their certification must cover the passive fire protection element they are installing.
 - Install all fire stopping systems in accordance with the manufacturer's written instructions and the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
 - Support centres for services passing through penetration seals serving fire barriers to be the same as those covered by the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
 - Install and inspect fire stopping systems in accordance with Building Regulations Approved Document B, ASFP Code of Practice TGD 17 and the general best practice guidance given in the ASFP On-site guide to installing fire-stopping.

210.015 STAINLESS STEEL PIPES AND FITTINGS:

- Manufacturer and reference Gervberit 316 Grade

- Welded stainless steel tubes for general purpose
 - Light gauge to BS EN 10312 - reference Y10.2220 for push and press-fit systems
 - Size range - nominal diameter (DN) up to and including 150mm
 - Size range - nominal diameter (DN)
 - Wall thickness - to be suitable for the application duty / testing requirements
 - Wall thickness in accordance with BS EN 10312
 - Table 2 - Series 2 (1mm - 3mm depending on OD)
 - To BS EN 10217-7 - reference Y10.2250B for general purpose use.
 - To ASTM A312 (dimensions determined by ANSI B36.19) for general use.
 - Joints - up to and including 50mm - screwed.
 - Joints - up to and including 50mm - welded and flanged.
 - Joints - 65mm and above - welded and flanged.
- Seamless stainless steel tubes for general purpose
 - To BS EN 10216-5 - reference Y10.2250A
 - To ASTM A312 (dimensions determined by ANSI B36.19)
 - Size - nominal diameter (DN) 200mm and above
 - Wall thickness - to be suitable for the application duty / testing requirements.
 - Grade of steel for general purpose
 - 316
- Seamless stainless steel tubes and fittings to BS 4825 for food and chemical industry applications - reference Y10.2230 and Y10.2240.
 - Size range - nominal diameter (DN)
 - Wall thickness - to be suitable for the application duty / testing requirements.
 - Wall thickness Minimum of 1mm
 - Grade of steel
 - 316S11
 - 316S13
 - 316S31
 - 316S33
- Stainless steel push-fit fittings - reference Y10.2257
- Stainless steel fittings, grooved for mechanical joints
 - Reference Y10.2255A
 - Reference Y10.2255#
- Mechanical joints, grooved stainless steel pipes reference Y10.3152A
- Light gauge stainless steel for push-fit and press-fit systems to BS EN 10312 - reference Y10.2220
- Light gauge stainless steel for push-fit and press-fit systems reference Y10.2221
- Use press fitting jointing system for stainless steel pipe for pressure purposes.
 - Jointing equipment for press fitting jointing system - reference Y10.3125
 - Press fittings for stainless steel pipe - reference Y10.3130#

210.025 MALABLE IRON / STEEL PIPES AND FITTINGS: PIPE-IN-PIPE:

- Application LTHW and Chilled Water Applications
 - Carbon steel pipes to BS EN 10253-1 or BS EN 10253-2
 - Heavy, black - reference Y10.2010A
 - Medium, black - reference Y10.2010B
 - Reference Y10.2010#
 - Carbon steel fittings to BS EN 10253-1 or BS EN 10253-2
 - Heavy weight - reference Y10.2060A
 - Medium weight - reference Y10.2060B
 - Malleable cast iron fittings, screwed
 - Black - reference Y10.2070A

- Jointing materials
 - Screwed joints to relevant parts of BS EN 10226
 - Paste and hemp and PTFE tape - reference Y10.3030A
 - PTFE tape - reference Y10.3030B
 - Where chemical cleaning is required - reference Y10.3030C
 - Union connections
 - Railroad pattern - spherical seating bronze to iron.
 - Navy pattern - spherical seating bronze to bronze.
 - Welding rods
- Reference Y10.3050A
- Outer pipe
 - Carbon steel pipes to BS EN 10255
 - Heavy, black - reference Y10.2010A
 - Medium, black - reference Y10.2010B
 - Carbon steel fittings to BS EN 10253-1 or BS EN 10253-2
 - Heavy weight - reference Y10.2060A
 - Medium weight - reference Y10.2060B
 - Malleable cast iron fittings, screwed
 - Black - reference Y10.2070A
 - Jointing materials
 - Screwed joints to BS 21 and BS EN 10226-1.
 - Paste and hemp and PTFE tape - reference Y10.3030A
 - PTFE tape - reference Y10.3030B
 - Where chemical cleaning is required - reference Y10.3030C
 - Union connections
 - Railroad pattern - spherical seating bronze to iron.
 - Navy pattern - spherical seating bronze to bronze.
 - Welding rods
- Reference Y10.3050A

210.060 OTHER PIPES AND FITTINGS:

210.090 WORKMANSHIP, STEEL PIPEWORK:

- Welding, general
 - Class 1 - reference Y10.5010A
 - Class 2 - reference Y10.5010B
- Welded joints - reference Y10.5020
- Painting welded joints - reference Y10.5030
- Flanged joints - reference Y10.5040
- Screwed joints - reference Y10.5050
- Mechanical joints - reference Y10.5060
- Anchors
 - U-bolts - reference Y10.5070A
- Flanges - reference Y10.5070B
- Pipework painting - reference Y10.5090
- Installation of stainless steel pipework
 - Compression joints - reference Y10.5100
 - Mechanical joints - Y10.5060

210.100 WORKMANSHIP, COPPER PIPEWORK:

- Compression joints - reference Y10.6030
- Capillary joints - reference Y10.6040
- Anchors
 - Flanges - reference Y10.6060A
- Saddle clamps - reference Y10.6060B

211.000 PIPELINE ANCILLARIES

211.010 GENERAL:

- Comply with work section general clauses below
 - Safety and relief valves, bursting discs, self-operated, application and standards - reference Y11.1010
- For applicable valves comply with BS EN 16668 for all essential safety requirements of the Pressure Equipment (Safety) Regulations 2016. Valves excluded from conformance to this standard in the Regulations shall meet "sound engineering practice" by conformity to the relevant product standard.
- Face to face and centre to face dimension of PN and Class designated flanged metal valves to be in accordance with BS EN 558
- In addition to the particular valve type standard, valves to be used in, or connected to, water supply pipe systems, above or below ground carrying water intended for human consumption to comply with the relevant parts of BS EN 1074 and BS 5163 as appropriate to the application.
 - BS EN 1074-1 - General requirements
 - BS EN 1074-2 - Isolating valves
 - BS EN 1074-3 - Check valves
 - BS EN 1074-4 - Air valves
 - BS EN 1074-5 - Control valves
 - BS EN 1074-6 - Hydrants
- Valves and components of valves specified are as defined in BS EN 736-1 and BS EN 736-2.
- Testing of valves
 - Pressure test metallic valves at manufacturer's works, in accordance with BS EN 12266-1 or BS ISO 5208 in conjunction with given specific requirements of the valve product or performance standard.
 - Undertake supplementary tests below in accordance with BS EN 12266-2 in conjunction with given specific requirements of the valve product or performance standard
 - Obturator strength
 - Back seat tightness
 - Operability
 - Anti-static design at 12V
 - Anti-static design at 100V
 - Fire tested design
 - Flow resistance
 - Pressure test thermoplastic valves at manufacturer's works, in accordance with BS ISO 9393-1 in conjunction with given specific requirements of the valve product or performance standard

211.030 STOP VALVES:

- Service fluid
- Water
- PN to suit system maximum working pressure.
- WRAS approved for water services applications.
- Comply with BS EN 1074-1 and BS EN 1074-2 in addition to the particular valve type standard, for valves for water supply applications carrying water for human consumption.
- Kitemark certified.
- Pipe material
 - To suit copper tube.

- To suit steel tube.
- Copper alloy globe type stop valves (stop cocks) to BS EN 1213 for potable water supplies
 - Compression ends for copper - reference Y11.2015A
 - Capillary - reference Y11.2015C
 - Threaded - reference Y11.2015D
- Copper alloy gate valves for general use to BS 5154
 - Screwed to BS EN ISO 228-1, or ISO 7-1 - reference Y11.2020A
 - Compression to BS EN 1254-2 - reference Y11.2020B
 - Flanged to BS EN 1092-3 - reference Y11.2020C
 - Loose nut/union end - reference Y11.2020D
- Cast iron gate valves for general use to BS EN 1171
 - Grey cast iron flanged to BS EN 1092-2 - reference Y11.2030A
- Copper alloy globe valves for general use to BS 5154
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2040A
 - Flanged to BS EN 1092-3 - reference Y11.2040B
 - Compression to BS EN 1254-2 - reference Y11.2040C
 - Compression to BS EN 1254-3 - reference Y11.2040D
- Cast iron globe valves for general use to BS EN 13789
 - Grey cast iron flanged to BS EN 1092-2 - reference Y11.2050A
- Steel parallel slide for steam and other high temperature / pressure applications to BS EN 1984
 - Reference Y11.2060A
- Steel wedge type gate valve for general use to BS EN 1984
 - Flanged to BS EN 1092-1 - reference Y11.2070A
 - Threaded - reference Y11.2070D
 - Auxiliary connections
- Ball valves
 - Application, standard and material
 - Potable water - copper alloy to BS EN 13828, PN 10 and distribution temperature of 65 °C with occasional excursions up to 90 °C permitted for a period of 1 hour maximum.
 - General purpose heating, cooling and other applications - copper alloy to BS EN 13547.
 - Steam and high temperature / pressure applications - steel to BS ISO 7121 - reference Y11.2160#.
 - Screw driver/key operated
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2080A
 - Compression to BS EN 1254-2 - reference Y11.2080B
 - Lever operated
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2080C
 - Compression to BS EN 1254-2 - reference Y11.2080D
 - Lockshield
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2080E
 - Compression to BS EN 1254-2 - reference Y11.2080F
- Servicing valves, for water services for maintenance of fittings / appliances, copper alloy to BS 6675
 - Handwheel operated
 - Screwed ends - reference Y11.2085A
 - Compression ends - reference Y11.2085B
 - Capillary ends - reference Y11.2085C
 - Lever operated
 - Screwed ends - reference Y11.2085D
 - Compression ends - reference Y11.2085E
 - Capillary ends - reference Y11.2085F
 - Screw driver operated
 - Screwed ends - reference Y11.2085G
 - Compression ends - reference Y11.2085H
 - Capillary ends - reference Y11.2085I

- Butterfly valves for general use to BS EN 593
 - Semi-lugged between flanges to BS EN 1092-2
 - Lever operated - reference Y11.2090A
 - Gear operated - reference Y11.2090B
 - Between mechanical joints
 - Lever operated - reference Y11.2090C
 - Gear operated - reference Y11.2090D
 - Fully-lugged to BS EN 593 - reference Y11.2090E
 - Lever operated.
- Gear operated.
- Cast iron gate type for waterworks purposes to relevant parts of BS 5163
- Key operated type A - reference Y11.2110A
- Closed bottom taper plug valves for gas installations for buildings to BS EN 331.

211.050 DOUBLE REGULATING VALVES:

- Service fluid
- Water
- WRAS approved.
- Kitemark certified.
- Pipe material
 - To suit copper tube.
 - To suit steel tube.
- Butterfly type to BS EN 593
 - Between flanges to BS EN 1092-2
 - Lever operated - reference Y11.2210A
 - Gear operated - reference Y11.2210B
 - Between mechanical joints
 - Lever operated - reference Y11.2210C
 - Gear operated - reference Y11.2210D
- Globe valves to BS 7350, section 3.1.
 - Copper alloy
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2220A
 - Flanged to BS EN 1092-2 - reference Y11.2220B
 - Cast iron
- Flanged to BS EN 1092-2 - reference Y11.2220C

211.060 FLOW MEASUREMENT VALVES:

- Service fluid
- Water
- WRAS approved.
- Kitemark certified.
- Pipe material
 - To suit copper tube.
 - To suit steel tube.
- Flow measurement devices to BS 7350
 - Section 3.2 Type 3
 - Copper alloy
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2230A
 - Flanged to BS EN 1092-3 - reference Y11.2230B
 - Cast iron
 - Flanged to BS EN 1092-2 - reference Y11.2230C

- Section 3.2 Type 4
 - Copper alloy
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2230E
 - Flanged to BS EN 1092-3 - reference Y11.2230F
 - Cast iron - reference Y11.2230G
 - Variable orifice valve
- Fixed orifice valve

211.065 PRESSURE INDEPENDENT CONTROL VALVES (PICV'S):

- Select, install and commission valves to provide the functions of flow limitation, modulating or on/off control and differential pressure control within a single valve body.
- Commission valves in accordance with the manufacturer's recommendations and Commissioning Specialists Association TM18.
- The valve manufacturer shall provide test results for each type and size of PICV to be used on the project in accordance with BSRIA Test Method for Pressure Independent Control Valves BTS 1/2012.
- Incorporate a flushing drain in the pipework between the terminal unit and the PICV.
- Type
 - Full stroke constant k_v where the control and flow setting functions are separated within the valve and the full stroke of the valve is available for control.
 - Full stroke variable k_v where the control valve section has a constant unchangeable stroke distance but its k_v can be varied by means of an inlet port with an adjustable opening size.
 - Stroke limited variable k_v where the control valve and flow setting devices are combined in a single component.
 - Globe.
 - Rotary, characterised ball.
 -
- Valve characteristic/control function
 - On/off.
 - Linear (modulating).
 - Equal percentage (modulating).
- Application
 - Heating terminal units
 - Cooling terminal units
- Heating and cooling terminal units
- Manufacturer and reference
 - Or approved equivalent.
- Duties
 - To suit terminal unit design flow rates as detailed in equipment schedules
- Duties and details as schedule reference Motorised Control Valvesd
 - Relevant parts of BS EN 60534
 - Valve leakage class to BS EN 60534-4 when shut off.
 - IV.
 -
 -
 -
- Maximum pressure differential (kPa)
- Minimum operating pressure differential for PICV operation (kPa)
- Materials
 - Body - DZR brass.
 - Globe or ball - brass.
 - Stem - brass.
 - O-Ring/diagram - EPDM rubber.

- Springs - stainless steel.
-
- Features
- Facility to measure pressure drop across valves at commissioning.
- Actuator
 - TRV actuator for radiators.
 - TRV with capillary sensor for radiators and radiant panels.
 - Thermo - electric on/off.
 - 0-10V proportional electric for modulating control.
- 3 point floating control.
- Prefabricated packaged valve assembly requirements
 - Type of heating/cooling terminal:
 - Fan coil units - heating and cooling.
 - Fan coil units - cooling only.
 - Chilled beams - heating and cooling.
 - Chilled beams - cooling only.
 - Chilled ceiling panels.
 - Radiators
 - Radiant panels
 -
- Components required:
 - PICV.
 - Ball type isolation valves on flow and return.
 - Flushing by-pass with 3-port valve.
 - Flushing blow down drain valve.
 - Flow measurement venturi for commissioning verification.
 -
- Component to be pre-assembled and tested at the manufacturer's works, test pressure (kPa)
-
- Labeling requirements

211.070 FLOW REGULATORS AND COMBINATION VALVES:

- Service fluid
- Water
- WRAS approved.
- Kitemark certified.
- Pipe material
 - To suit copper tube.
- To suit steel tube.

211.075 HEAT METERS:

- Manufacturer and reference Kamstrup - Ultrasonic
 - Or approved equivalent.
- Standards
 - Meters - BS EN 1434-1, BS EN 1434-2, BS EN 1434-3, BS EN 1434-4, BS EN 1434-5
 - Heat meter installation commissioning, operational monitoring and maintenance - BS EN 1434-6
 - Provide heat meters with integrator, flow sensor, matched pair of temperature sensors and interconnecting cables calibrated as a single unit at manufacturer's works. Installations to be in accordance with manufacturer's recommendations.
 - RHI compliant heat meters and their installation shall meet the requirements of the following:
 - The Renewable Heat Incentive Scheme Regulations 2018 as amended.
 - The most recent version of Ofgem Renewable Heat Incentive Guidance Volume One: Eligibility and

How to Apply.

- Annex MI-004 of the EU Measuring Instruments Directive (MID) 2004/22/EC refer to Directive 2014/32/EU from 20th April 2016.
- Commissioning to be carried out by the manufacturer.
- Metering installation arrangement for RHI eligibility
 - Standard metering
 - Multiple metering
- Meter accuracy class for RHI eligibility as defined in Annex MI-004 of the MID/BS EN 1434-1
 - Class 2.
- For RHI installation with a capacity of 45Wth and below the installation shall be undertaken by a Microgeneration Certification Scheme (MCS) certified installer.
- For RHI installation of a capacity of 1MWth and above or when the installation is classed as a multiple metering arrangement or steam is to be metered, provide an independent report on metering as defined by Ofgem.
- Arrangement
 - In-line.
- Service fluid
 - Water.
 - Water/Glycol mix (% Glycol)

211.080 TEST PLUGS:

- Self sealing test points - reference Y11.2670A
- Valve controlled test points - reference Y11.2670B

211.090 RADIATOR VALVES TO BS 2767:

- Manufacturer and reference Herz Valves
- Kitemark certified.
- Type 4 - reference Y11.2260A
 - Finish
- Natural.

211.100 PIPELINE STRAINERS:

- Bronze (Y type)
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2680A
 - Flanged to BS EN 1092-3 - reference Y11.2680B
 - Compression to BS EN 1254-2
Reference Y11.2680C
- Cast iron/ductile iron
 - Y type - flanged to BS EN 1092-2 - reference Y11.2680D
 - Flanged suction diffuser type reference Y11.2680G
 - Cast iron body with ductile iron cover and cast iron guide vanes (PN16)
 - Ductile iron body and cover, and ductile guide vanes (PN25)
- Ductile iron grooved ends
 - Y type - reference Y11.2680E
 - Suction diffuser strainer - reference Y11.2680F

211.110 THERMOSTATIC RADIATOR VALVES TO BS EN 215:

- Application Remote with capillary for ceiling mounted radiant panels
 - Manufacturer and reference Herz Valves
- Kitemark certified.

- Table A.1 - Series D - reference Y11.2270A
 - Pattern
 - Straight
 - Angle

211.120 TUNDISHES:

- Copper - reference Y11.2690A

211.140 GAUGES:

- General - reference Y11.2700A
 - 150mm black stoved enamel finish
 - Flush panel mounting - reference Y11.2700B
 - Direct mounting - reference Y11.2700C
- 100mm - finish
- Temperature gauges general - reference Y11.2710A
 - Mercury in steel - reference Y11.2710B
 - Vapour pressure to BS EN 13190
 - Direct mounting - reference Y11.2710C
- Pressure and altitude gauges - reference Y11.2720
- Vacuum gauges - reference Y11.2730
- Differential pressure gauges
 - Hardwood - reference Y11.2750A

211.150 CONTROL VALVES:

- WRAS approved.
- Kitemark certified.
- Ball control valves
 - Open/close - reference Y11.2315A
 - Two way - reference Y11.2315B
 - Three way - reference Y11.2315C

211.160 LOOSE ITEMS:

- Keys for spindle shank valves - reference Y11.3010A
 - Number
- For drain cocks - reference Y11.3010B
- Number

211.170 CHECK VALVES:

- WRAS approved.
- Kitemark certified.
- Service fluid
- Water.
- Pipe material
 - To suit copper tube.
 - To suit steel tube.
- Copper alloy check type to BS 5154
 - Swing type screwed to relevant parts of BS EN 10226 - reference Y11.2320A
 - Swing type flanged to BS EN 1092-3 - reference Y11.2320B
- Steel and cast iron check valves to BS EN 16767
 - Swing check
 - Flanged - reference Y11.2330A
 - Grooved for mechanical joints.
 - Wafer body - reference Y11.2330B
 - Lift check
 - Flanged - reference Y11.2330C
 - Wafer body - reference Y11.2330D
 - Body material
 - Grey cast iron
 - Malleable cast iron
 - SG cast iron
 - Steel
- Wafer flange fitting type
- Reference Y11.2340A
- Steel globe stop and check type to BS EN 13709 - reference Y11.2370#
- Device to prevent contamination of water by backflow to BS EN 14451
 - Combined check and anti-vacuum - reference Y11.2385A
- Anti-back syphonage valve, combined check and anti-vacuum type
 - Reference Y11.2390A
- Anti-back syphonage valve, hose union anti-vacuum type
- Reference Y11.2391A

211.180 WORKMANSHIP:

- Installation - reference Y11.4010

- Location - reference Y11.4020
 - Positions
- Location of thermostatic radiator valves - reference Y11.4025
- Positioning of components
 - Flow/pressure measurement valves - reference Y11.4030
 - Double regulating variable orifice valves - reference Y11.4040
 - Install control ball valves in accordance with manufacturer's recommendations.
 - Control components
 - Reference Y11.4050A
- Provide outlets of vent cocks with discharge pipes.
- Valve stuffing boxes - reference Y11.4070
- Discharge connections
 - Safety and Relief valves - reference Y11.4080A
 - Vent cocks - reference Y11.4080B
 - Air bottles - reference Y11.4080C
 - Automatic air vents - reference Y11.4080D
- Expansion devices - reference Y11.4090
- Expansion compensators - reference Y11.4100
- Flexible connections installation - reference Y11.4110
- Terminal unit connections - install hose connections strictly in accordance with manufacturer's instructions.

211.210 DRAIN COCKS:

- WRAS approved.
- Kitemark certified.
- Throughway gland cock type
 - Reference Y11.2440A
- Screwdown to BS 2879, type 1 - reference Y11.2450
- Ball type - reference Y11.2460

211.220 VENT COCKS:

- Kitemark certified.
- Two way gland cock type - reference Y11.2470
- Ball type - reference Y11.2480
- Three way gland cock type - reference Y11.2490
- Plug valve type
 - Wrench operated - reference Y11.2500A
 - Gear operated - reference Y11.2500B

211.230 AUTOMATIC AIR VENTS:

- Application At high points on LTHW systems
 - Manufacturer and reference Spirotech - Spirotop AAV's
- Float type
 - Reference Y11.2510A

211.260 EXPANSION ARRANGEMENTS/DEVICES AND FLEXIBLE CONNECTIONS/HOSES:

Expansion Bellows and Flexible Hose Compensatorsps

- Steel
 - Reference Y11.2610A

- Galvanized after manufacture.
- Copper - reference Y11.2620
- Expansion compensators
 - Axial bellows
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2630A
 - Flanged to BS EN 1092-1 - reference Y11.2630B
 - Articulated bellows
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2630D
 - Flanged to BS EN 1092-1 - reference Y11.2630E
 - Slip-type axial, grooved and expansion compensators
 - Reference Y11.2630J
 - Multiple grooved couplings type compensators
 - Reference Y11.2630K
- Hose compensators
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2640A
 - Flanged to BS EN 1092-1 - reference Y11.2640B
 - Standard
 - Corrugated metal hoses to comply with BS EN 14585-1 and PD CEN/TR 14585-3
- Flexible connections for noise and vibration attenuation
 - EPDM rubber, up to 100°C
 - Flanged to BS EN 1092-1 - reference Y11.2650A
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2650B
 - Grooved flexible mechanical joints for noise and vibration attenuation
 - Install 3 grooved flexible mechanical joints after the source of vibration and before the first change in pipe direction. Installation to be strictly in accordance with the manufacturer's instructions.
 - Convoluted stainless steel, above 100°C
 - Flanged to BS EN 1092-1 - reference Y11.2650C
 - EPDM rubber, up to 70°C
 - Flanged to BS EN 1092-1 - reference Y11.2650D
 - Screwed to relevant parts BS EN 10226 - reference Y11.2650E
 - Chlorobutyl rubber, up to 100°C
 - Flanged to BS EN 1092-1 - reference Y11.2650F
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2650G
 - Chlorobutyl rubber, up to 60°C
 - Flanged to BS EN 1092-1 - reference Y11.2650H
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2650I
- Terminal heating and cooling unit connections
 - Heating services
 - Stainless steel - reference Y11.2660A
 - Stainless steel with quick release couplings - reference Y11.2660B
 - Rubber - reference Y11.2660C
 - Chilled water services
 - Stainless steel - reference Y11.2660D
 - Stainless steel with quick release couplings - reference Y11.2660E
 - Rubber - reference Y11.2660F
 - Corrugated metal hoses to comply with BS EN 14585-1 and PD CEN/TR 14585-3
- Flexible hose assemblies for drinking water installations to connect sanitary tap ware, heaters and similar appliances with maximum operating temperature 70°C to be in accordance with BS EN 13618. Flexible hose assemblies intended for use as integral parts of appliances, to be in accordance with BS EN 61770
- Hose and hose assemblies for saturated steam and hot water condensate.
 - Application
 - Standard - BS EN ISO 6134

- Type 1 - low pressure, maximum working pressure 6 bar
- Type 2 - high pressure, maximum working pressure 18 bar
- Incorporate an oil-resistant cover

225.000 CLEANING AND CHEMICAL TREATMENT

225.010 GENERAL:

- Comply with work section general clauses below
 - Conditions for cleaning and chemical treatment - reference Y25.1010
 - Method statement - reference Y25.1015
- Comply with Approved Codes of Practice and associated technical guidance published by HSE on the requirements of the Health and Safety at Work etc. Act 1974 and the Control of Substances Hazardous to Health Regulations 2002 as amended, that apply to the risk from exposure to legionella bacteria.

225.020 CLEANING AND CHEMICAL TREATMENT SPECIALIST:

- Reference Y25.2010
 - Use one of the following specialists Phoenix Commissioning, COTS, Contract Engineering, or NHS current term maintenance contractor that looks after the QUEH and RHC Building/Systems
- On closed systems the specialist shall, in addition to specific requirements detailed elsewhere in this specification or drawings, undertake the following:
 - Obtain relevant information on the closed system to be treated.
 - Evaluate which treatment options will achieve the corrosion control and water quality objectives, taking account of regulatory issues and product selection constraints.
 - Follow up the treatment programme with proper monitoring of chemical, microbiological and physical parameters, ideally including monitoring of corrosion rates.
- On open evaporation cooling systems the specialist shall, in addition to specific requirements detailed elsewhere in this specification or drawings, review the design and confirm the system can be operated and maintained in accordance with HSE L8 Approved Code of Practice and Guidance - Legionnaire's' Disease: The control of legionella bacteria in water systems and associated technical guidance in HSG274 Part 1: The control of legionella bacteria in evaporative cooling systems.

225.040 PRELIMINARY CHECKS:

- Reference Y25.2030A
- Systems applicable Domestic Water Systems, LTHW, Chilled Water Systems

225.050 PROCEDURAL PRECAUTIONS:

- Reference Y25.2040A
- Including taking samples - reference Y25.2040B

225.060 CHEMICAL INJECTION AND DOSING METHODS:

- Water treatment methods
 - Reference Y25.2050#
 - Water treatment methods for hot water heating closed circuit recirculating systems - reference Y25.2050A
 - Water treatment methods for chilled and condenser water closed circuit recirculating systems - reference Y25.2050B
 - Water treatment methods for cooling tower hot water heating closed circuit recirculating systems - reference Y25.2050C
- Method of introducing chemicals into closed systems - reference Y25.2060A

- Method of introducing chemicals into open recirculating systems - reference Y25.2060B
- Packaged plant - reference Y25.2060C
- Dosing for closed systems - reference Y25.2060D
- Dosing pot capacity to be sized by water treatment specialist to suit system capacity and chemicals used.
- Dosing for open systems - reference Y25.2060E
- Dosing chemicals - reference Y25.2065

225.065 CORROSION TEST COUPON RACKS:

- Type
 - Serpentine, incorporating isolation valves on both sides of the rack and built-in flow control to hold the water flow through the rig at the ASTM recommended velocity of 0.6m/s to 1.8m/s.
- Standard
- ASTM D2688

225.090 FLUSHING:

- Application
 - Heating, cooling and other closed pipework systems
 - BSRIA Guide BG 29/2012 - Pre-commission Cleaning of Pipework Systems - reference Y25.3010B
 - System filling
 - Temporary connection from mains in compliance with
 - England and Wales - The Water Supply (Water Fittings) Regulations 1999 as amended, the Water Act 2014 and The Construction Products Regulations 2013.
 - Scotland - The Water Supply (Water Fittings) Byelaws 2014.
 - Northern Ireland - The Water Supply (Water Fittings) Regulations 2009.
 - Temporary connection from fire hydrant pipework.
 - By installation of temporary tank and pump arrangement.
 - Flush system until discharge water is visually clear.
- Services supplying water for domestic use - reference Y25.3010D

225.100 PURGING:

- Testing and purging gas pipework from the outlet of the Emergency Control Valve (ECV) fitted on the end of the gas service that is owned by the Gas Transporter and the inlet connection to the gas appliance.
 - Industrial and commercial installation - reference Y25.3020A
- Small low pressure industrial and commercial installations (having a volume not exceeding 1m³) - reference Y25.3020B

225.110 CHEMICAL CLEANING AND SOLIDS REMOVAL:

- BSRIA Application Guide 29/2012: Pre-commission Cleaning of Pipework Systems.
 - Inhibited acid - reference Y25.3030A
 - Formulated products - reference Y25.3030B
- Cleaning and chemical treatment regime - reference Y25.3035

225.120 DISINFECTION:

- General - reference Y25.3040
- Hot and cold water systems - reference Y25.3050

225.150 DOCUMENTATION:

- Reference Y25.3090

230.000 AIR DUCTLINES AND ANCILLARIES

230.010 GENERAL:

- Comply with work section general clauses below
 - Ductwork installation standards - reference Y30.1010
 - Ductwork dimensions - reference Y30.1020
- Electrical bonding terminal - reference Y30.1030
- Location Refer to (57) Series Drawings
- Fire stopping
 - All components forming the seal system to be from the same manufacturer. All products used, to have third party product certification by a scheme accredited by UKAS.
 - Only use UKAS accredited, third party installer certified specialist contractors. The specialists should be ASFP members and their certification must cover the passive fire protection element they are installing.
 - Install all fire stopping systems in accordance with the manufacturer's written instructions and the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
 - Support centres for services passing through penetration seals serving fire barriers to be the same as those covered by the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
 - Install and inspect fire stopping systems in accordance with Building Regulations Approved Document B, ASFP Code of Practice TGD 17 and general best practice guidance given in the ASFP On-site guide to installing fire-stopping.

230.020 INSTALLER SELECTION:

- Use a member of the BESA (Building Engineering Services Association) specialising in manufacturing and installing ductwork.
- Where post installation cleaning is specified, appoint a specialist cleaning contractor to undertake the work in accordance with BESA TR/19, and supply and install any additional cleaning openings to suit their selected specific methods of cleaning and to suit the practical site conditions relative to the fabric of the building and position of other services.
- Existing systems that require inspection and cleaning prior to modification or re-commissioning (including kitchen extract systems).
 - Employ a specialist, approved in accordance with Loss Prevention Standard LPS 2084, to undertake the following:

230.030 DUCTWORK AND FITTINGS:

- Type Refer to (57) Series Drawings
- Application Supply and Extract Ventilation systems as detailed
 - Electrical bonding terminal - reference Y30.1030
- Design Information
 - Pressure classification
 - Class A, positive - reference Y30.2010A
 - Class A, negative - reference Y30.2010B
 - Cleanliness quality class to BS EN 15780 and BESA TR/19
 - High.
 - Prior to final commissioning, in addition to a visual assessment of the internal surfaces, undertake Preferred Vacuum Test (PVT) to establish dust accumulation level is within the acceptable level for the

cleanliness quality class listed in Table 2 (A.4) in BESA TR/19.

- Protection Delivery and Installation (PDI) level to BS EN 15780 and BESA TR/19
- Advanced (including post installation cleaning) - reference Y30.4090C
- Reference Y30.4090#
- Post installation cleaning for advance level of PDI
 - To be undertaken by a ductwork cleaning specialist.
 - Dry method - reference Y30.4090D
 - Wet method - reference Y30.4090E
 - Medium pressure ductwork - reference Y30.2030B
 - Low pressure ductwork - reference Y30.2030C
- Ductwork strength and air leakage testing, circular sheet metal ductwork - reference Y30.2035
- Ductwork strength and air leakage testing, rectangular sheet metal ductwork - reference Y30.2036.

230.040 SHEET METAL DUCTWORK TO DW/144:

- Material
 - Zinc coated. Hot-dip galvanised steel to BS EN 10346.
 - Pre-coated steel.
- Protective finishes
 - Galvanizing.
 - Metal spraying.
 - Paint.
- Construction
 - Rectangular.
 - Circular.
 - Man access and safety bars - reference Y30.2070

230.070 FIRE RESISTING / SMOKE EXTRACT DUCTWORK AND METHOD OF MAINTAINING FIRE INTEGRITY:

- Type and method of fire rating 2 Hour
- Fire protection material Specialist Coatings - Paint and Applied Materials
- Ventilation systems to be protected Refer to (57) Series Drawing for locations and Specific Ductwork that is to be fire rated
- Install and inspect fire resisting duct systems in accordance with Building Regulations and ASFP Code of Practice TGD 18.
- The installation shall be fully in accordance with the test certification.
- Supply fire resisting ductwork as schedule reference Fire Rated Ductwork
- Supply fire resisting ductwork as below
 - Duct type
 - Fire outside duct Type A
 - Application
 - Fire protection of supply and extract ventilation ductwork
 - Fire resistance when tested to the requirements of BS EN 1366-1, BS EN 1366-8 or BS EN 1366-9 and classified in accordance with BS EN 13501-3 for ventilation ducts or BS EN 13501-4 for smoke control ducts using BS EN "EI" nomenclature by UKAS accredited certification body.
 - Integrity 120 mins
 - Fire rating when tested to the requirements of BS 476-24 by a UKAS accredited certification body.
 - Thermal insulation requirements
 - As detailed in Y 50 / D1.9.10.
 - Minimum thickness to control heat loss and heat gain in accordance with Building Regulations.
- Pressure class of ductwork to BESA DW/144: Classs
 - Smoke and heat control duct systems to BS EN 12101-7

- BS 9999 for general fire safety
- BS EN 1363-1 Fire resistance tests. General requirements
- BS EN 1366-1 Fire resistance tests for service installations. Ventilation ducts
- BS EN 1366-9 Fire resistance tests for service installations. Single compartment smoke extraction ducts
- BS EN 13501-3 Classification using data from fire resistance tests on products and elements used in building service installations: fire resisting ducts and fire dampers
- BS EN 13501-4 Classification using data from fire resistance tests on components of smoke control systems
- Fire protection with fire dampers or automatically actuated fire and smoke dampers triggered by smoke detectors - reference Y30.2110A
- Fire protection with fire resisting enclosures
- Reference Y30.2110B
- Fire resisting ductwork tested to BS EN 1366 - reference Y30.2110E
 - Fire resisting and smoke / heat control ductwork tested to BS EN 1366 - reference Y30.2110F
- The manufacturer/installer shall be assessed and registered in accordance with BS EN ISO 9001
- Systems/materials shall be listed within the Loss Prevention Certification Board (LPCB) Red Book.
- Systems/materials used shall have third party accreditation by a UKAS accredited certification body.

230.080 INSULATED DUCTWORK:

- Type Supply and Extract systems
 - Application for heat recovery and acoustic issues
- External thermal/acoustic insulation
 - Reference Y30.2121

230.090 SUPPORTS:

- Hangers and supports
 - Reference Y30.2140A
- Support of air terminal units
 - Reference Y30.2150A

230.100 ACCESSORIES:

- Construction and finishes - reference Y30.3010
- Inspection/servicing access openings
 - Metal ductwork - reference Y30.3020A
 - BESA TR/19 - reference Y30.3020D
- Test holes
 - Metal ductwork - reference Y30.3030A
- Holes for controls/instruments - metal ductwork - reference Y30.3040
- Installation of instruments and controls - reference Y30.3042
- Cleaning access
 - Basic level of PDI - reference Y30.3050A
 - Intermediate level of PDI - reference Y30.3050B
 - Advanced level of PDI with post installation cleaning - reference Y30.3050C
- Flexible joint connections
 - Reference Y30.3110A

230.110 REGULATING DAMPERS - METAL DUCTWORK:

- Type Fire Stop Dampers and Isolation Dampers
- Manufacturer and reference Halton and Actionair

- Or approved equivalent.
- Acoustic testing requirements to BS EN ISO 5135
- Balancing dampers
 - Steel single-blade dampers - reference Y30.3060A
 - Steel multi-blade dampers - reference Y30.3060B
- Control dampers
 - Steel single-blade dampers - reference Y30.3060C
- Steel multi-blade dampers - reference Y30.3060D

230.150 COMBINATION SMOKE AND FIRE DAMPERS:

- Type Refer to (50) Series and (57) Series Drawings
- Application Fire Smoke Dampers
- Manufacturer and reference Actionair
- Control mode To Suit Existing - Refer to Entropic
- General - reference Y30.3089
- Steel single-blade - reference Y30.3090A
- Steel multi-blade - reference Y30.3090B
- Combination smoke control / fire dampers to be in accordance with BS EN 12101-8 tested to BS EN 1366-10 and BS EN 1366-2 and classified in accordance with BS EN 13501-4.

230.180 AIR DUCTLINES & ANCILLARIES WORKMANSHIP:

- General - reference Y30.4010
- Ductwork supports - reference Y30.4020
- Component support on pre-insulated aluminium ductwork
 - Reference Y30.4025
- Duct support for vapour seal continuity
 - Reference Y30.4030A
- External ductwork
 - Construction
 - Galvanised steel to BESA DW/144 Section 26, protected from the elements by a watertight membrane installed immediately after the ductwork has been installed.
 - Galvanised steel to BESA DW/144 Section 26 not protected by a watertight membrane.
 - Insulation
 - Refer to Thermal Insulation specification clauses / schedule.
 - Protective finish
 - Painting
 - Aluminium cladding.
 - Laminating foil / film jacketing system
 - External ductwork supports - reference Y30.4040
 - As shown on drawings
- Ductwork floor support - reference Y30.4050
- Drainage of ductwork - reference Y30.4060
- Connections to building openings
 - Metal ductwork, comply with DW/144, Appendix K.
- Weather proofing
 - Flashing plate and cowl - reference Y30.4100A
 - Ductwork sleeves
 - Flanged - reference Y30.4110B
- Fire rated ductwork sleeves
 - Provide as indicated on drawing.
- Installation of control equipment

- Reference Y30.4130
- Positions
 - Position components as indicated and in accordance with manufacturer's instructions as shown on the following drawings
 - Contract drawings.
 - Manufacturer's drawings.
 - Specialist supplier's drawings.
 - Specialist contractor's drawings.
- Instrument connections
 - Reference Y30.4140
- Damper access - reference Y30.4160

241.000 FANS

241.010 GENERAL:

- Comply with general clauses below
 - Standards
 - Reference Y41.1000
 - Design duties, fan selection, efficiency and EC ecodesign requirements for fans and ventilation units.
 - Reference Y41.1010
 - Protection
 - Reference Y41.1020
- Supply fans as schedule reference Fans Referecne AHU specification and Schedules
 - Location Level 4 new Plant Room
- Ensure all electrical equipment supplied and installed is suitable for power supply indicated.
- Provide details of electrical input, starting and performance characteristics of all motors above 750W to an agreed format.
- Where appropriate ensure motors and drives are supplied complete with keys and keyways.
- Supply fans as schedule reference (50) Series Drawing

241.020 FAN AND MOTOR:

- Application
 - Included in air handling unit reference AHU AHU/01 and AHU/02 Supply and AHU/01 and AHU/02 Extract
 - Manufacturer and reference
 - Select fans from Quality Assured firms.
 - Fully Eurovent Certified as an assembly and for individual components
 - Or approved equivalent.
- Electrical supply to BS EN 60038
 - Single-phase.
 - 3-phase.
 - 3-phase and neutral. BS EN 10143
 - Construct casing from mild steel coated with epoxy polyester finish.
- Motor
 - Type
 - Asynchronous induction with Variable Speed Drive (VSD).
 - Permanent-Magnet Synchronous, with Variable Speed Drive (VSD).
 - Magnet free synchronous reluctance with VSD.
 - EC Permanent-Magnet Synchronous with integral AC to DC converter and electronic controls with 0-10V control input.
 - EC Permanent-Magnet Synchronous with integral AC to DC converter and electronic controls with

- 0-10V control input and integral PID controller to enable sensors to be connected directly to the motor.
- Standards - reference Y92.1010
- General - reference Y92.2020
 - Provide protected enclosures against external mechanical impacts in accordance with BS EN 62262
 - IK 08.
- On belt driven fan fit motors on slide rails - reference Y92.2030
- Motor efficiency
 - Efficiency class - IE2 - reference Y92.2025A
 - Efficiency class - IE3 - reference Y92.2025B
 - Efficiency class - IE4 - reference Y92.2025C
- Degree of protection in accordance with BS EN 60034-5
 - IP55.
 - Method of motor cooling in accordance with BS EN 60034-6
- Surge suppressors
 - Manufacturer fitted - reference Y92.1040A
- Motor operating conditions
 - Standard operating conditions
 - Non standard operating conditions (above 1000m with air conditions exceeding 40°C and 50%
- Motors - over temperature protection
 - Thermistors - reference Y92.2060A
 - Reference Y92.2060#
- Drives
 - Indirect drives
 - Toothed belt - reference Y92.2070A
 - Flat belt - reference Y92.2070B
 - Direct coupled drives
 - Reference Y92.2080A
 - Variable speed drives (VSDs)
 - Frequency converters (VSD) tailor made for HVAC application
 - Located in control panel or exposed wall or frame mounted - reference Y72.2190A
 - Located in motor control centre - reference Y72.2190B
 - Reference Y72.2190#
 - Demarcation of responsibilities and location of VSD
 - Integrated with pump motor, supplied and selected by pump manufacturer to suit design duty
 - Supplied and selected by the controls specialist to suit plant duty and provided as part of local plant controls for integration with BMS
 - Located remote from motor
 - Guards
 - Reference Y92.2090A
 - Motor mounting classification - reference Y92.2100#

241.050 WORKMANSHIP

- Location - reference Y41.4010
- Attitude - reference Y41.4020
- Alignment - reference Y41.4030
- Testing - reference Y41.4040
- Drain connections - reference Y41.4050

250.000 THERMAL INSULATION

250.010 GENERAL:

- Comply with work section general clauses reference below
 - Temperature range - reference Y50.1010
 - Standards - reference Y50.1020
 - Materials - reference Y50.1030
 - Pre-insulated equipment - reference Y50.1032
 - Protection applied in situ - reference Y50.1034
 - European classification for reaction to fire performance - reference Y50.1035A
 - European classification for reaction to fire performance - reference Y50.1035#
 - Spread of flame - reference Y50.1050A
 - Spread of flame - reference Y50.1050#
 - Smoke emission characteristics - reference Y50.1055
 - Electrical bonding terminal - reference Y50.1080
- Inspection and testing - reference Y50.1090
- Make good any sections that are cut during inspection for thickness and compliance with specification.
- Insulation thicknesses
 - Reference Y50.2289

250.020 INSTALLER SELECTION:

- Use a contractor specialising in the supply and installation of thermal insulation.
- Use thermal insulation materials supplied by a manufacturer assessed and registered in accordance with BS EN ISO 9001.
- Use thermal insulation materials supplied by a manufacturer assessed and registered in accordance with BS EN ISO 14001.
- Use thermal insulation materials supplied by a manufacturer assessed and registered in accordance with BS OHSAS 18001

250.030 MINERAL WOOL THERMAL INSULATION - PIPEWORK:

- Reference Y50.1035A
- Spread of flame as BS 476-7
 - Reference Y50.1050A
- Smoke emission characteristics
 - Reference Y50.1055
- Electrical bonding terminal - reference Y50.1080
- Inspection and testing - reference Y50.1090
- Materials
 - Standard - BS EN 14303.
- Thermal conductivity - reference Y50.2010
- Thermal performance life expectancy
 - For plant design life - reference Y50.2015A
 - Details - reference Y50.2015B
- Restrictions on use of materials - reference Y50.2020
- Mineral wool pipe insulation
 - Foil faced - Rock mineral wool reference Y50.2030A
 - Canvas covered - Rock mineral wool reference Y50.2030B
 - Foil faced - Glass mineral wool reference Y50.2030C
 - Canvas covered - Glass mineral wool reference Y50.2030D
 - Vapour barrier permeance
- Vapour barrier coatings
 - Bitumen - reference Y50.2180A
 - Vinyl - reference Y50.2180B

- Solvent polymers- reference Y50.2180C
- Bitumen emulsion- reference Y50.2180D
- Adhesives - reference Y50.2190
- Protection
 - Application
 - Self-adhesive multi-layer laminate covering - reference Y50.2200A
 - Roofing felt - reference Y50.2200B
 - Flat aluminium-zinc coated steel - reference Y50.2200C
 - Ribbed aluminium-zinc coated steel - reference Y50.2200D
 - Aluminium sheeting - reference Y50.2200E
 - Canvas - reference Y50.2200G
 - Canvas with aluminium bands - reference Y50.2200H
 - Reinforcement
- Valve and flange insulation
 - Application
- Thickness table
 - Insulation thickness calculation methods, Building Regulations - reference Y50.2286
 - Insulation thickness calculation methods, ECA Enhanced - reference Y50.2287
 - Insulation thickness tables - reference Y50.2289
 - Non-domestic hot water supply services Building Regulations (rock mineral wool) - reference Y50.2290

 - Phenolic foam - reference Y50.2430

- Nitrile rubber - reference Y50.2440
- Insulation thickness on ductwork, Building Regulations - reference Y50.2456
- Condensation control on chilled air ductwork
 - Rock mineral wool - reference Y50.2460
 - Phenolic foam - reference Y50.2470
 - Closed cell nitrile foam - reference Y50.2475
- Thickness of insulation to BS 5422 for process pipework and equipment- reference Y50.2490#.
- Thickness of insulation to BS 5422 for refrigeration pipework and equipment -reference Y50.2495#
- Thickness of insulation

250.090 WORKMANSHIP PIPEWORK INSULATION:

- General - reference Y50.3010
- Installation of foil faced mineral wool insulation - reference Y50.3020
- Installation of foil faced phenolic foam insulation - reference Y50.3030
- Installation of closed cell nitrile rubber insulation - reference Y50.3050
- Installation of protection
 - Polyisobutylene (PIB) - reference Y50.3120
 - Self-adhesive multi-layer laminate covering - reference Y50.3125
 - Sheet metal finish
 - Reference Y50.3130A
 - Canvas - reference Y50.3150
 - Roofing felt - reference Y50.3160
 - Aluminium sheeting - reference Y50.3170
 - Aluminium-zinc coated steel - reference Y50.3180
 - Rigid PVC - reference Y50.3190
- Flanges and valves - reference Y50.3210
- Installation where insulation is carried through pipeline support
 - Reference Y50.3230A
 - Closed cell insulation - reference Y50.3230B
- Liquid vapour barriers - reference Y50.3260
- Integrity of vapour barriers - reference Y50.3270

250.100 WORKMANSHIP DUCTWORK INSULATION:

- General - reference Y50.3010
- Installation of foil faced rigid or slotted slab insulation - reference Y50.3060
- Installation of foil faced flexible insulation - reference Y50.3070
- Installation of foil faced lamella insulation - reference Y50.3080
- Installation of protection
 - Polyisobutylene (PIB) - reference Y50.3120
 - Self-adhesive multi-layer laminate covering - reference Y50.3125.
 - Sheet metal finish
 - Reference Y50.3140A
 - Canvas - reference Y50.3150
 - Roofing felt - reference Y50.3160
 - Aluminium sheeting - reference Y50.3170
 - Aluminium-zinc coated steel - reference Y50.3180
 - Rigid PVC - reference Y50.3190
- Installation where insulation is carried through ductwork support - reference Y50.3250
- Liquid vapour barriers - reference Y50.3260
- Integrity of vapour barriers - reference Y50.3270

250.110 WORKMANSHIP EQUIPMENT INSULATION:

- General - reference Y50.3010
- Installation of insulation on tanks - reference Y50.3090
- Installation of mineral wool insulation on vessels - reference Y50.3100
- Installation of phenolic foam insulation on vessels - reference Y50.3110
- Installation of protection
 - Polyisobutylene (PIB) - reference Y50.3120
 - Self-adhesive multi-layer laminate covering - reference Y50.3125
 - Sheet metal finish
 - Reference Y50.3140A
 - Canvas - reference Y50.3150
 - Roofing felt - reference Y50.3160
 - Aluminium sheeting - reference Y50.3170
 - Aluminium-zinc coated steel - reference Y50.3180
 - Rigid PVC - reference Y50.3190
- Liquid vapour barriers - reference Y50.3260
- Integrity of vapour barriers - reference Y50.3270

251.000 TESTING AND COMMISSIONING OF MECHANICAL SERVICES**251.010 GENERAL:**

- Carry out testing and commissioning as specified in section SHTM 03-01

251.020 SPECIALIST:

- Use a commissioning specialist who is a member of The Commissioning Specialists Association (CSA).
- Or approved equivalent

251.030 STATIC TESTING:

- Carry out air pressure and leakage testing on air ductwork in accordance with specification section covering air ductlines and ancillaries.
- Carry out pressure / leakage testing of builders work air shafts, voids and floor plenums where they are used for supply ventilation - reference Y51.2015
- Pressure testing
 - General - reference Y51.2010
 - Hot and cold water supply systems, water circulating systems (LTHW, MTHW, HTHW, chilled and condenser water) and steam and condense lines - reference Y51.2020
 - Underground pipework
 - Test pre-insulated bonded steel pipe systems for district heating in accordance with BS EN 13941.
 - Test pre-insulated non bonded pipe systems in accordance with the system manufacturer's recommendations.
 - Test pre-insulated bonded flexible pipe systems in accordance with the system manufacturer's recommendations.
 - Underground cold water supply mains - reference Y51.2040
 - Fire risers - reference Y51.2050
 - Refrigerant pipework
 - Strength pressure test - reference Y51.2055A
 - Leak test - reference Y51.2055B
 - Deep vacuum test - reference Y51.2055C

- Gas pipework
 - Pressure testing - reference Y51.2060
- Oil pipework - reference Y51.2065
- Piped medical gases - reference Y51.2070
- Condense and overflow systems - reference Y51.2075
- Soil, waste, ventilation, anti-syphon and rainwater pipework - reference Y51.2080
- Underslab drainage - reference Y51.2090
- Vacuum testing - reference Y51.2100
- Provide an air compressor and subject the pipework to sectional testing by air at low pressure (not exceeding 0.5 bars) before commencing any flushing or testing with water.
- On completion of all cleaning, flushing and air testing operations, recharge each system with clean water and subject them to sectional hydraulic tests of one and a half times the working pressure.
- There is to be no loss of pressure for a period of not less than 30 minutes for each test.

251.040 COMMISSIONING:

- Commissioning codes - reference Y51.3020
- Commissioning
 - Water distribution
 - Including BSRIA pre-commissioning check list
 - Reference Y51.3030
 - Air distribution
 - Including BSRIA pre-commissioning check list
 - Reference Y51.3040
 - Automatic control systems - reference Y51.3070
- Instruments and gauges
 - Reference Y51.3090A
- Commissioning records
 - Distribution
 - For air systems
 - To BSRIA Guide BG 49/2015 - reference Y51.3100A
 - For water systems
 - To BSRIA Guide BG 2/2010 - reference Y51.3100B
- BMS commissioning
 - Control system specification details required for commissioning - reference Y51.3110
 - Pre-commissioning - reference Y51.3120
 - Plant ready for control system commissioning
 - Reference Y51.3130A
 - Control system requirements for plant commissioning - reference Y51.3140
 - Commissioning of building services as required by Scottish Technical Handbook Section 6.7.
 - Commissioning - reference Y51.3150

251.050 PERFORMANCE TESTING:

- System performance testing - reference Y51.4010
- Testing of residential ventilation systems - reference Y51.4015
- Where applicable, on ventilation facilities correct the measured air flow rate when ambient measuring conditions are different from standard conditions in accordance with PD CEN/TS 17153.
- Specific Fan Power Validation tests
 - After fitting clean filters, air handling systems to be commissioned under validation load. Measure the specific fan power SFP of each system for calculation of the building "as constructed" CO₂ emission rate.
 - Details

- Environmental tests for HVAC systems
 - Artificial loads - reference Y51.4020A
 - Ambient Air Quality - reference Y51.4020B
- Recorders - reference Y51.4030
 - Seven day space temperature recorders
 - Number
 - For (weeks) Two
 - Relative humidity recorders
 - Number
 - For (weeks) Two coils
-

252.000 VIBRATION ISOLATION MOUNTINGS

252.010 GENERAL:

- Comply with work section general clauses below
 - Design intent - reference Y52.1010
 - Spring anti vibration mountings - reference Y52.1020
 - Locking facility - reference Y52.1040
- Supply plant and pipework vibration isolation as schedule reference

252.020 MAT AND PAD MOUNTINGS:

- Duty
- Configured mat mountings
 - Neoprene/composite fibre/synthetic rubber
 - Reference Y52.2010A
 - Natural rubber - reference Y52.2010B
 - High temperature synthetic rubber
 - Reference Y52.2010C
- Resilient mat mountings
 - Cast in base - reference Y52.2010D
- Pad mountings
- Composite synthetic rubber - reference Y52.2010E

252.030 MOUNTINGS:

- Turret compression mountings
 - Synthetic rubber - reference Y52.2020A
 - Lockable facility - reference Y52.1040
 - Neoprene - reference Y52.2020B
 - Lockable facility - reference Y52.1040
- Spring compression mountings - reference Y52.2030
 - Lockable facility - reference Y52.1040
- Captive spring mountings - reference Y52.2040

252.040 EQUIPMENT HANGINGS:

- Spring compression hangers - reference Y52.2060
 - Lockable facility - reference Y52.1040
- Combined turret/spring compression hangers
 - Synthetic rubber - reference Y52.2070A

- Lockable facility - reference Y52.1040
- Neoprene - reference Y52.2070B
- Lockable facility - reference Y52.1040

252.050 PIPEWORK HANGERS:

- Spring compression hangers - reference Y52.2060
 - Lockable facility - reference Y52.1040
- Combined turret/spring compression hangers
 - Synthetic rubber - reference Y52.2070A
 - Lockable facility - reference Y52.1040
 - Neoprene - reference Y52.2070B
 - Lockable facility - reference Y52.1040

252.060 HORIZONTALLY RESTRAINED SPRING MOUNTINGS:

- Horizontally restrained spring mountings
 - Reference Y52.2080
 - Lockable facility - reference Y52.1040

252.070 INERTIA BASES:

- Manufacturer and reference.
- Reinforced concrete - reference Y52.2090A
 - Lockable facility - reference Y52.1040
- Welded steel frame - reference Y52.2090B
- Lockable facility - reference Y52.1040

252.080 VIBRATION ISOLATION HOSES:

- Vibration isolation hoses - reference Y52.2100
-

252.090 PIPEWORK NOISE VIBRATION ISOLATION:

- Natural corkwood - reference Y52.2110A
- Reconstituted corkwood granules - reference Y52.2110B
- Rubber matting - reference Y52.2110C

252.100 WORKMANSHIP:

- Horizontally restrained spring mountings - reference Y52.3040

252.110 PIPE, WALL AND RISER SEALS:

- Sponge foam packing - reference Y52.2120A
- Mineral fibre packing - reference Y52.2120B

254.000 IDENTIFICATION - MECHANICAL

254.010 GENERAL:

- Comply with work section general clauses below

- Requirements - reference Y54.1010
- New systems - reference Y54.1020
- Existing systems - reference Y54.1030
- Colours - reference Y54.1040
- Performance and durability - reference Y54.1045

254.020 PIPEWORK IDENTIFICATION:

- Reference Y54.2010

254.030 DUCTWORK IDENTIFICATION:

- Reference Y54.2020

254.040 PLANT AND EQUIPMENT IDENTIFICATION:

- Type Generally in line with current NHS GGC convention and Asset Registers
- Application Client to confirm exact details
 - Lettering
 - Laminated plates, multi-coloured with outer layer removed for lettering - reference Y54.2030B

254.045 GRAPHICAL SYMBOLS FOR USE ON EQUIPMENT IN ACCORDANCE WITH BS EN 80416:

- Reference Y54.2035

254.050 VALVE AND COCK IDENTIFICATION:

- Reference Y54.2040

254.070 LABORATORY OUTLETS:

- Type
- Application

254.080 AIR VOLUME REGULATING AND CONTROL DAMPER IDENTIFICATION:

- Reference Y54.2070

254.090 INSTRUMENT IDENTIFICATION:

- Reference Y54.2080

254.100 DANGER AND WARNING NOTICES:

- Reference Y54.2090

290.000 FIXING TO BUILDING FABRIC

290.010 GENERAL:

- Comply with work section general clauses below
 - Preparation - reference Y90.1010
 - Manufacturer's drawings - reference Y90.1020
 - Fixings - reference Y90.1030

- Loading details - reference Y90.1040
- Building-in by others - reference Y90.1050
- Size of fixing - reference Y90.1060
- Greasing of fixings - reference Y90.1070

290.020 FIXINGS:

- Standards - reference Y90.2010
- Plugs - reference Y90.2020
- Screws - reference Y90.2030
- Non-penetrative support systems - reference Y90.2080
 - Manufacturer and reference
 - Or approved equivalent.

290.030 WORKMANSHIP:

- Drilling - reference Y90.3010
- Fixing to timber rails - reference Y90.3050
- Fixing to hollow stud/tile/block wall
 - Reference Y90.3060A
- Fixing to concrete, brickwork or blockwork
 - Reference Y90.3070A
- Fixing to metalwork
 - Reference Y90.3080A
- Fixing to structural steelwork and concrete structures
 - Reference Y90.3090A
- Non-penetrative support systems for roof mounted equipment - reference Y90.3100#

291.000 OFF-SITE PAINTING AND ANTI-CORROSION TREATMENT

291.010 GENERAL

- Comply with work section general clauses below
 - General requirements - reference Y91.1010
- Damaged finishes - reference Y91.1020

291.020 PAINT MATERIALS:

- Paint materials
 - Reference Y91.2010A
- Paint quality - reference Y91.2020

291.030 WORKMANSHIP

- Weather and other conditions - reference Y91.3020
- Cleaning and preparing for painting
 - Steel surfaces - reference Y91.3030A
 - Surfaces - reference Y91.3030B
 - Reference Y91.3030#
- Application off-site - reference Y91.3040
- Application - reference Y91.3050
- Cold galvanizing - reference Y91.3060
- Protection of bright machine parts - reference Y91.3070

BS APPENDIX

BS 476-3:2004

Fire tests on building materials and structures. Part 3 Classification and method of test for external fire exposure to roofs

BS 476-4:1970

Fire tests on building materials and structures. Part 4 Non-combustibility test for materials

BS 476-6:1989+A1:2009

Fire tests on building materials and structures. Part 6 Method of test for fire propagation for products

BS 476-7:1997

Fire tests on building materials and structures. Part 7 Method of test to determine the classification of the surface spread of flame of products

BS 476-10:2009

Fire tests on building materials and structures. Part 10 Guide to principles, selection, role and application of fire testing and their outputs

BS 476-11:1982

Fire tests on the building materials and structures. Part 11 Method for assessing the heat emission from building materials

BS 476-12:1991

Fire tests on building materials and structures. Part 12 Method of test for ignitability of products by direct flame impingement

BS 476-13:1987, ISO 5657:1986

Fire tests on building materials and structures. Part 13 Method of measuring the ignitability of products subjected to thermal irradiance

BS 476-20:1987

Fire tests on building materials and structures. Part 20 Method for determination of the fire resistance of elements of construction (general principles)

BS 476-20:1987

Fire tests on building materials and structures. Part 20 Method for determination of the fire resistance of elements of construction (general principles)

BS 476-21:1987

Fire tests on building materials and structures. Methods for determination of the fire resistance of loadbearing elements of construction

BS 476-22:1987

Fire tests on building materials and structures. Part 22 Method for determination of the fire resistance of non-loadbearing elements of construction

BS 476-24:1987, ISO 6944:1985

Fire tests on building materials and structures. Part 24 Method for determination of the fire resistance of ventilation ducts

BS 476-31.1:1983

Fire tests on building materials and structures. Part 31.1 Methods for measuring smoke penetration through doorsets and shutter assemblies. Method of measurement under ambient temperature conditions

BS 476-32:1989

Fire tests on building materials and structures. Part 32 Guide to full scale fire tests within buildings

BS 476-33:1993, ISO 9705:1993

Fire tests on building materials and structures. Part 33 Full-scale room test for surface products

BS 2767:1991

Specification for manually operated copper alloy valves for radiators

BS 2879:1980

Specification for draining taps (screw-down pattern)

BS 4825-1:1991+A2:2009

Stainless steel tubes and fittings for the food industry and other hygienic applications. Part 1 Specification for tubes

Partially replaced by BS EN 10357:2013

BS 4825-2:1991+A2:2009

Stainless steel tubes and fittings for the food industry and other hygienic applications. Part 2 Specification for bends and tees

BS 4825-3:1991+A2:2009

Stainless steel tubes and fittings for the food industry and other hygienic applications. Part 3 Specification for clamp type couplings

BS 4825-4:1991+A1:2009

Stainless steel tubes and fittings for the food industry and other hygienic applications. Part 4 Specification for threaded (IDF type) coupling

BS 4825-5:1991+A1:2009

Stainless steel tubes and fittings for the food industry and other hygienic applications. Part 5 Specification for recessed ring joint type couplings

BS 5154:1991

Specification for copper alloy globe, globe stop and check, check and gate valves.

Partially replaced by BS EN 12288

BS 5163-1:2004

Valves for waterworks purposes. Part 1 Predominantly key-operated cast iron gate valves. Code of practice

BS 5163-2:2004

Valves for waterworks purposes. Part 2 Stem caps for use on isolating valves and associated water control apparatus. Specification

BS 5422:2009

Method for specifying thermal insulating materials for pipes, tanks, vessels, ductwork and equipment operating within the temperature range -40°C to +700°C

BS 6675:1986

Specification for servicing valves (copper alloy) for water services

BS 7350:1990

Specification for double regulating globe valves and flow measurement devices for heating and chilled water systems

BS 9999:2017

Fire safety in the design, management and use of buildings. Code of practice

BS EN 215-1:1991

Thermostatic radiator valves. Part 1 Requirements and test methods

BS EN 215:2004

Thermostatic radiator valves. Requirements and test methods

BS EN 331:2015

Manually operated ball valves and closed bottom taper plug valves for gas installations for buildings

BS EN 558:2017

Industrial valves. Face-to-face and centre-to-face dimensions of metal valves for use in flanged pipe systems. PN and Class designated valves

BS EN 593:2017

Industrial valves. Metallic butterfly valves for general purposes.

BS EN 736-1:2018

Valves. Terminology. Definition of types of valves

BS EN 736-2:2016

Valves. Terminology. Definition of components of valves

BS EN 1074-1:2000

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. General requirements

BS EN 1074-1:2000

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. General requirements

BS EN 1074-2:2000

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. Isolating valves

BS EN 1074-2:2000

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. Isolating valves

BS EN 1074-3:2000

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. Check valves

BS EN 1074-4:2000

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. Air valves

BS EN 1074-5:2001

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. Control valves

BS EN 1074-6:2008

Valves for water supply. Fitness for purpose requirements and appropriate verification tests. Hydrants

BS EN 1092-1:2018

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 1 steel flanges

BS EN 1092-2:1997

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 2 cast iron flanges

BS EN 1092-3:2003

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 3 copper alloy flanges

BS EN 1092-4:2002

Flanges and their joints. Circular flanges for pipes, valves, fittings and accessories, PN designated. Part 4 aluminium alloy flanges

BS EN 1171:2015

Industrial valves. Cast iron gate valves

BS EN 1213:2000

Building valves. Copper alloy stopvalves for potable water supply in buildings. Tests and requirements

BS EN 1254-2:1998

Copper and copper alloys. Plumbing fittings. Part 2 fittings with compression ends for use with copper tubes

BS EN 1254-3:1998

Copper and copper alloys. Plumbing fittings. Part 3 Fittings with compression ends for use with plastics pipes

BS EN 1363-1:2012

Fire resistance tests. General requirements

BS EN 1366-1:2014

Fire resistance tests for service installations. Ventilation ducts

BS EN 1366-1:2014

Fire resistance tests for service installations. Ventilation ducts

BS EN 1366-2:2015

Fire resistance tests for service installations. Part 2 Fire dampers

BS EN 1366-3:2009

Fire resistance tests for service installations. Penetration seals

BS EN 1366-3:2009

Fire resistance tests for service installations. Penetration seals

BS EN 1366-4:2006+A1:2010

Fire resistance tests for service installations. Linear joint seals

BS EN 1366-4:2006+A1:2010

Fire resistance tests for service installations. Linear joint seals

BS EN 1366-5:2010

Fire resistance tests for service installations. Service ducts and shafts

BS EN 1366-6:2004

Fire resistance tests for service installations. Part 6 Raised access and hollow core floors

BS EN 1366-7:2004

Fire resistance tests for service installations. Part 7 Conveyor systems and their closures

BS EN 1366-8:2004

Fire resistance tests for service installations. Part 8 Smoke extraction ducts

BS EN 1366-8:2004

Fire resistance tests for service installations. Part 8 Smoke extraction ducts

BS EN 1366-9:2008

Fire resistance tests for service installations. Single compartment smoke extraction ducts

BS EN 1366-9:2008

Fire resistance tests for service installations. Single compartment smoke extraction ducts

BS EN 1366-10:2011+A1:2017

Fire resistance tests for service installations. Part 10 Smoke control dampers

BS EN 1366-12:2014

Fire resistance tests for service installations. Non-mechanical fire barrier for ventilation ductwork

BS EN 1434-1:2015+A1:2018

Thermal energy meters. General requirements

BS EN 1434-1:2015+A1:2018

Thermal energy meters. General requirements

BS EN 1434-2:2015+A1:2018

Thermal energy meters. Constructional requirements

BS EN 1434-2:2015+A1:2018

Thermal energy meters. Constructional requirements

BS EN 1434-3:2015

Heat Meters. Data exchange and interfaces

BS EN 1434-3:2015

Heat Meters. Data exchange and interfaces

BS EN 1434-4:2015+A1:2018

Thermal energy meters. Pattern approval tests

BS EN 1434-4:2015+A1:2018

Thermal energy meters. Pattern approval tests

BS EN 1434-5:2015+A1:2019

Thermal energy meters. Initial verification tests

BS EN 1434-5:2015+A1:2019

Thermal energy meters. Initial verification tests

BS EN 1434-6:2015+A1:2019

Thermal energy meters. Installation, commissioning, operational monitoring and maintenance

BS EN 1434-6:2015+A1:2019

Thermal energy meters. Installation, commissioning, operational monitoring and maintenance

BS EN 1984:2010

Industrial valves. Steel gate valves

BS EN 10143:2006

Continuously hot-dip coated steel sheet and strip. Tolerances on dimensions and shape

BS EN 10216-1:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 1 Non-alloy steel tubes with specified room temperature properties

BS EN 10216-1:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 1 Non-alloy steel tubes with specified room temperature properties

BS EN 10216-2:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 2 Non-alloy and alloy steel tubes with specified elevated temperature properties

BS EN 10216-2:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 2 Non-alloy and alloy

steel tubes with specified elevated temperature properties

BS EN 10216-3:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 3 Alloy fine grain steel tubes

BS EN 10216-3:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 3 Alloy fine grain steel tubes

BS EN 10216-4:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 4 Non-alloy and alloy steel tubes with specified low temperature properties

BS EN 10216-4:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 4 Non-alloy and alloy steel tubes with specified low temperature properties

BS EN 10216-5:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 5 Stainless steel tubes

BS EN 10216-5:2013

Seamless steel tubes for pressure purposes. Technical delivery conditions. Part 5 Stainless steel tubes

BS EN 10217-1:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 1 Non-alloy steel tubes with specified room temperature properties

BS EN 10217-1:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 1 Non-alloy steel tubes with specified room temperature properties

BS EN 10217-2:2002+A1:2005

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 2 Electric welded non-alloy and alloy steel tubes with specified elevated temperature properties

BS EN 10217-2:2002+A1:2005

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 2 Electric welded non-alloy and alloy steel tubes with specified elevated temperature properties

BS EN 10217-3:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 3 Alloy fine grain steel tubes

BS EN 10217-3:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 3 Alloy fine grain steel tubes

BS EN 10217-4:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 4 Electric welded non-alloy steel tubes with specified low temperature properties

BS EN 10217-4:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 4 Electric welded non-alloy steel tubes with specified low temperature properties

BS EN 10217-5:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 5 Submerged arc welded non-alloy and alloy steel tubes with specified elevated temperature properties

BS EN 10217-5:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 5 Submerged arc welded non-alloy and alloy steel tubes with specified elevated temperature properties

BS EN 10217-6:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 6 Submerged arc welded non-alloy steel tubes with specified low temperature properties

BS EN 10217-6:2002

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 6 Submerged arc welded non-alloy steel tubes with specified low temperature properties

BS EN 10217-7:2014

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 7 Stainless steel tubes

BS EN 10217-7:2014

Welded steel tubes for pressure purposes. Technical delivery conditions. Part 7 Stainless steel tubes

BS EN 10226-1:2004

Pipe threads where pressure tight joints are made on the threads. Taper external threads and parallel internal threads. Part 1 dimensions, tolerances and designation

BS EN 10226-2:2005

Pipe threads where pressure tight joints are made on the threads. Taper external threads and taper internal threads. Dimensions, tolerances and designation

BS EN 10226-3:2005

Pipes threads where pressure-tight joints are made on the threads. Verification by means of limit gauges

BS EN 10253-1:1999

Butt-welding pipe fittings. Part 1 Wrought carbon steel for general use and without specific inspection requirements

BS EN 10253-2:2007

Butt-welding pipe fittings. Part 2 Non alloy and ferritic alloy steels with specific inspection requirements

BS EN 10253-3:2008

Butt-welding pipe fittings. Wrought austenitic and austenitic-ferritic (duplex) stainless steels without specific inspection requirements

BS EN 10253-4:2008

Butt-welding pipe fittings. Wrought austenitic and austenitic-ferritic (duplex) stainless steels with specific inspection requirements

BS EN 10255:2004

Non-alloy steel tubes suitable for welding and threading. Technical delivery conditions

BS EN 10312:2002

Welded stainless steel tubes for the conveyance of aqueous liquids including water for human consumption. Technical delivery conditions

BS EN 10346:2015

Continuously hot-dip coated steel flat products for cold forming. Technical delivery conditions

BS EN 12101-3:2015

Smoke and heat control systems. Specification for powered smoke and heat control ventilators (Fans)

BS EN 12101-7:2011

Smoke and heat control systems. Part 7 Smoke duct sections

BS EN 12101-8:2011

Smoke and heat control systems. Part 8 Smoke control dampers

BS EN 12266-1:2012

Industrial valves. Testing of valves. Pressure tests, test procedures and acceptance criteria. Mandatory requirements

BS EN 12266-2:2012

Industrial valves. Testing of metallic valves. Tests, test procedures and acceptance criteria. Supplementary requirements

BS EN 13190:2001

Thermal insulation products for buildings. Factory made products of phenolic foam (PF). Specification

BS EN 13501-2:2016

Fire classification of construction products and building elements. Classification using data from fire resistance tests, excluding ventilation services

BS EN 13501-3:2005+A1:2009

Fire classification of construction products and building elements. Part 3 Classification using data from fire resistance tests on products and elements used in building service installations: fire resisting ducts and fire dampers

BS EN 13501-4:2016

Fire classification of construction products and building elements. Classification using data from fire resistance tests on components of smoke control systems

BS EN 13547:2013

Industrial valves. Copper alloy ball valves

BS EN 13618:2016

Flexible hose assemblies in drinking water installations. Functional requirements and test methods

BS EN 13709:2010

Industrial valves. Steel globe and globe stop and check valves

BS EN 13789:2010

Industrial valves. Cast iron globe valves

BS EN 13828:2003

Building valves. Manually operated copper alloy and stainless steel ball valves for potable water supply in buildings. Tests and requirements

BS EN 13941:2009+A1:2010

Design and installation of pre-insulated bonded pipe systems for district heating

BS EN 14303:2015

Thermal insulation products for building equipment and industrial installations. Factory made mineral wool products (MW). Specification.

BS EN 14451:2005

Devices to prevent pollution by backflow of potable water. In-line anti-vacuum valves DN 8 to DN 80. Family D, type A

BS EN 14585-1:2006

Corrugated metal hose assemblies for pressure applications. Requirements

BS EN 15780:2011

Ventilation for buildings. Ductwork. Cleanliness of ventilation systems

BS EN 16668:2016+A1:2018

Industrial valves. Requirements and testing for metallic valves as pressure accessories

BS EN 16767:2016

Industrial valves. Steel and cast iron check valves

BS EN 60034-5:2001

Rotating electrical machines. Part 5 Degrees of protection provided by the integral design of rotating electrical machines (IP code). Classification

BS EN 60034-6:1994, IEC 60034-6:1991

Rotating electrical machines. Part 6 Methods of cooling (IC Code)

BS EN 60038:2011

CENELEC standard voltages

BS EN 60534-1:2005

Industrial-process control valves. Control valve terminology and general considerations

BS EN 60534-2-1:2011

Industrial-process control valves. Flow capacity. Sizing equations for fluid flow under installed conditions

BS EN 60534-2-3:2016

Industrial-process control valves. Flow capacity. Test procedures

BS EN 60534-2-4:2009

Industrial-process control valves. Flow capacity. Inherent flow characteristics and rangeability

BS EN 60534-2-5:2003

Industrial-process control valves. Flow capacity. Sizing equations for fluid flow through multistage control valves with interstage recovery

BS EN 60534-3-1:2000, IEC 60534-3-1:2000

Industrial-process control valves. Dimensions. Face-to-face dimensions for flanged, two-way, globe-type, straight pattern and centre-to-face dimensions for flanged, two-way, globe-type, angle pattern control valves

BS EN 60534-3-2:2001, IEC 60534-3-2:2001

Industrial-process control valves. Dimensions. Face-to-face dimensions for rotary control valves except

butterfly valves

BS EN 60534-3-3:1998, IEC 60534-3-3:1998

Industrial-process control valves. Dimensions. End-to-end dimensions for butt-weld, two-way, globe-type, straight pattern control valves

BS EN 60534-4:2006

Industrial-process control valves. Inspection and routine testing

BS EN 60534-5:2004

Industrial-process control valves. Marking

BS EN 60534-6-1:1998, IEC 60534-6-1:1997

Industrial-process control valves. Mounting details for attachment of positioners to control valves. Positioner mounting on linear actuators

BS EN 60534-6-2:2001, IEC 60534-6-2:2000

Industrial-process control valves. Mounting details for attachment of positioners to control valves. Positioner mounting on rotary actuators

BS EN 60534-7:2010

Industrial-process control valves. Control valve data sheet

BS EN 60534-8-1:2005

Industrial-process control valves. Noise considerations. Laboratory measurement of noise generated by aerodynamic flow through control valves

BS EN 60534-8-2:2011

Industrial-process control valves. Noise considerations. Laboratory measurement of noise generated by hydrodynamic flow through control valves

BS EN 60534-8-3:2011

Industrial-process control valves. Noise considerations. Control valve aerodynamic noise prediction method

BS EN 60534-8-4:2015

Industrial-process control valve. Noise considerations. Prediction of noise generated by hydrodynamic flow

BS EN 60534-9:2007

Industrial-process control valves. Test procedure for response measurements from step inputs

BS EN 61770:2009+A11:2018

Electric appliances connected to the water mains. Avoidance of backsiphonage and failure of hose-sets

BS EN 62262:2002

Degrees of protection provided by enclosures for electrical equipment against external mechanical impacts (IK code)

BS EN 80416-1:2009

Basic principles for graphical symbols for use on equipment. Part 1 Creation of symbol originals

BS EN 80416-2:2001

Basic principles for graphical symbols for use on equipment. Part 2 Form and use of arrows

BS EN 80416-3:2002+A1:2011

Basic principles for graphical symbols for use on equipment. Part 3 Guidelines for the application of graphical symbols

BS EN ISO 228-1:2003

Pipe threads where pressure-tight joints are not made on the threads. Part 1 Dimensions, tolerances and designation

BS EN ISO 5135:1999

Acoustics. Determination of sound power levels of noise from air-terminal devices, air-terminal units, dampers and valves by measurement in a reverberation room

BS EN ISO 6134:2017

Rubber hoses and hose assemblies for saturated steam. Specification

BS EN ISO 9001:2015

Quality management systems. Requirements

BS ISO 5208:2015

Industrial valves. Pressure testing of metallic valves

BS ISO 7121:2016

Steel ball valves for general-purpose industrial applications

BS ISO 9393-1:2004

Thermoplastics valves for industrial applications. Pressure test methods and requirements. General

ISO 7-1:1994

Pipe threads where pressure-tight joints are made on the threads. Part 1 Dimensions, tolerances and designation

T - COOLING DISTRIBUTION

PRIMARY / SECONDARY COOLING DISTRIBUTION

PART 1 SYSTEM OBJECTIVES

100.010 PERFORMANCE OBJECTIVES

- New Chilled Water Distribution System – Reference (55) Series Drawings.38

100.011 PERFORMANCE OBJECTIVES

The purpose of this specification is that the primary/secondary cooling distribution systems, plant and equipment provided in compliance with it, will deliver the whole hospital engineering design philosophies and be compliant with all Department of Health (NHS Estates) documentation including, but not limited to SHTM's and SHBN's pertinent to the nature of the project.

100.030 SYSTEM DESCRIPTION

- Alteration and extension to existing systems as required to allow for new Chilled Water Distribution systems as required for the project

100.060 SYSTEM DRAWINGS

Refer to the (55) Series Drawings

PART 2 SELECTION SCHEDULES FOR REFERENCE SPECIFICATIONS

210.000 PIPELINES AND PIPEWORK

210.010 GENERAL:

- Comply with work section general clauses below
 - prefabricated pipework - reference Y10.1010
- Fire stopping
 - All components forming the seal system, to be from the same manufacturer
 - Comply with BS 9999, relevant approved technical guidance to Building Regulations and BESA Technical Bulletin TB/032
 - Provide proprietary penetration seal system. All products used, to have third party product certification by a scheme accredited by UKAS.
 - Type
 - Stone mineral wool, soft seal type lamella strip with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. For use in all applications including where movement of services needs to be accommodated. Tested and assessed to BS EN 1366-3 and BS EN 1366-4 and classified to BS EN 13501-2.
 - Stone mineral wool ablative coated batt seal with a proprietary flexible coating, used in conjunction with acoustic intumescent sealant and/or high expansion intumescent sealant to suit the application. Tested and assessed to BS EN 1366-3.
 - All services passing through apertures in masonry walls/concrete floors or drywall partitions/systems.
 - Fire resistance
 - 2 hrs.
- Only use UKAS accredited, third party installer certified specialist contractors. The specialists should

be ASFP members and their certification must cover the passive fire protection element they are installing.

- Install all fire stopping systems in accordance with the manufacturer's written instructions and the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
- Support centres for services passing through penetration seals serving fire barriers to be the same as those covered by the test / assessment / certification evidence provided by the installer / manufacturer of the penetration seal.
- Install and inspect fire stopping systems in accordance with Building Regulations Approved Document B, ASFP Code of Practice TGD 17 and the general best practice guidance given in the ASFP On-site guide to installing fire-stopping.

210.020 CARBON STEEL PIPES AND FITTINGS:

- Welded carbon steel tubes
 - To BS EN 10225, heavy, black - reference Y10.2010A
 - Size - nominal diameter (DN) up to and including 150mm.
 - Size - nominal diameter (DN)
 - To BS EN 10225, medium, black - reference Y10.2010B
 - Size - nominal diameter (DN) up to and including 150mm.
 - Size - nominal diameter (DN)
 - To BS EN 10217-1 - reference Y10.2050
 - Size - nominal diameter (DN) 200mm and above.
 - Size - nominal diameter (DN)
 - Wall thickness - to be suitable for the application duty / testing requirements.
 - Wall thickness
 - Joints - up to and including 50mm - screwed.
 - Joints - up to and including 50mm - welded and flanged.
 - Joints - 65mm and above - welded and flanged.
 - Heavy black, grooved ends to BS EN 10255 - reference Y10.2010E
 - Medium, black, grooved ends to BS EN 10255 - reference Y10.2010F
 - Medium, galvanized, grooved ends - reference Y10.2010H
- Seamless carbon steel tubes
 - To BS EN 10225, heavy, black - reference Y10.2010A
 - Size - nominal diameter (DN) up to and including 150mm.
 - Size - nominal diameter (DN)
 - To BS EN 10225, medium, black - reference Y10.2010B
 - Size - nominal diameter (DN) up to and including 150mm.
 - Size - nominal diameter (DN)
 - To BS EN 10216-1 - reference Y10.2030
 - Size - nominal diameter (DN) 200mm and above.
 - Size - nominal diameter (DN)
 - Wall thickness - to be suitable for the application duty / testing requirements.
 - Wall thickness
 - Joints - up to and including 50mm - screwed.
 - Joints - up to and including 50mm - welded and flanged.
 - Joints - 65mm and above - welded and flanged.
 - Joints - grooved ends for mechanical joints.
 - Carbon steel pipes for push-fit and press-fit systems
- Light gauge galvanised - reference Y10.2012A
- Butt welding carbon steel fittings.
 - To BS EN 10253-1 for general use without specific inspection requirements - reference Y10.2060A
 - To BS EN 10253-2 with specific inspection requirements for use on applications covered by the Pressure Equipment (Safety) Regulations 2016 - reference Y10.2060B
- Malleable cast iron fittings, screwed

- Black - reference Y10.2070A
- Galvanised - reference Y10.2070B
- Steel threaded pipe fittings
 - Type
 - Seamless fittings manufactured from seamless tube, forging or rolled bar.
 - Fabricated fittings manufactured from welded tube or where welding forms part of the fabrication of the fitting.
 - Reference Y10.2090
 - Fittings, grooved for mechanical joints
 - Galvanised cast iron - reference Y10.2080E
 - Painted steel - reference Y10.2080F
 - Special materials
- Jointing materials
 - Circular flanges
 - Flanges to BS EN 1092-1 and BS ISO 7005-1
 - PN
 - Class
 - Welding flanges - reference Y10.3010A
 - Screwed flanges - reference Y10.3010B
 - Jointing rings for circular flanges
 - Non-metallic flat for flanges to BS EN 1092-1 - reference Y10.3020A
 - Metallic for flanges to BS EN 1092-1 - reference Y10.3020B
 - Screwed joints to relevant parts of BS EN 10226
 - Paste and hemp and PTFE tape - reference Y10.3030A
 - PTFE tape - reference Y10.3030B
 - Where chemical cleaning is required - reference Y10.3030C
 - Union connections
 - Railroad pattern - spherical seating bronze to iron.
 - Navy pattern - spherical seating bronze to bronze.
 - Welding rods
 - Reference Y10.3050A

210.060 OTHER PIPES AND FITTINGS:

210.080 GENERAL WORKMANSHIP:

- Appearance - reference Y10.4010
- Spacing - reference Y10.4020
- Gradients - reference Y10.4030
- Air venting requirements
 - Air bottles - reference Y10.4040A
 - Automatic air vents - reference Y10.4040B
- Drain requirements - reference Y10.4050
- Expansion and contraction - reference Y10.4060
- Pipe fittings
 - Bends/swept tees - reference Y10.4070A
 - Elbows/square tees - reference Y10.4070B
- Pipes through walls and floors - reference Y10.4110
- Protect pipework penetrating fire separating elements in accordance with, Building Regulations, BS 9999 and BESA Technical Bulletin TB/032.
- Pipe sleeves
 - Reference Y10.4120A
 - Insulation carried through - reference Y10.4120B
- Pipe through fire barriers - reference Y10.4125

- Type
 - Proprietary sleeves
 - Ablative coated batt type
- Fire resistance
 - 2 hours
 - hrs
- Connect to equipment.
- Use distribution headers.
- Temporary plugs, caps and flanges
 - Reference Y10.4150A.
- Flanged joints general - reference Y10.4160
- Dissimilar metals - reference Y10.4170
- Pipe rings and clips - reference Y10.4180
 - Anchors - reference Y10.4190
- Pipe supports - reference Y10.4205
 - Comply with the manufacturers' installation recommendations for the following proprietary pipe systems:
 -
- Isolation and regulation
 - Reference Y10.4230A
- Maintenance and renewal - reference Y10.4240
- Clean by removing cement and clean off all pipework and brackets.
- Non-ferrous components - thoroughly clean and degrease.
- Pipe collars (closers) for plastic pipes where they pass through fire resistant walls and floors.
 - Type
 - Stainless steel collar with fixing brackets with intumescent liner.
 - Pre-assembled wrap for casing within concrete floor or masonry wall.
 - Fire resistance
 - 2 hrs
 - Installation to be in accordance with the manufacturer's instructions and grouted/sealed using the manufacturer's proprietary compound/sealant.
 - Standards
 - Test to BS EN 1366-3 and BS EN 1363-1.
 - Test to BS 476-20.

210.090 WORKMANSHIP, STEEL PIPEWORK:

- Welding, general
 - Class 1 - reference Y10.5010A
 - Class 2 - reference Y10.5010B
- Welded joints - reference Y10.5020
- Painting welded joints - reference Y10.5030
- Flanged joints - reference Y10.5040
- Screwed joints - reference Y10.5050
- Mechanical joints - reference Y10.5060
- Anchors
 - U-bolts - reference Y10.5070A
- Flanges - reference Y10.5070B
- Pipework painting - reference Y10.5090
- Installation of stainless steel pipework
 - Compression joints - reference Y10.5100
 - Mechanical joints - Y10.5060

211.000 PIPELINE ANCILLARIES**211.010 GENERAL:**

- Comply with work section general clauses below
 - Safety and relief valves, bursting discs, self-operated, application and standards - reference Y11.1010
- For applicable valves comply with BS EN 16668 for all essential safety requirements of the Pressure Equipment (Safety) Regulations 2016. Valves excluded from conformance to this standard in the Regulations shall meet "sound engineering practice" by conformity to the relevant product standard.
- Face to face and centre to face dimension of PN and Class designated flanged metal valves to be in accordance with BS EN 558
- In addition to the particular valve type standard, valves to be used in, or connected to, water supply pipe systems, above or below ground carrying water intended for human consumption to comply with the relevant parts of BS EN 1074 and BS 5163 as appropriate to the application.
 - BS EN 1074-1 - General requirements
 - BS EN 1074-2 - Isolating valves
 - BS EN 1074-3 - Check valves
 - BS EN 1074-4 - Air valves
 - BS EN 1074-5 - Control valves
 - BS EN 1074-6 - Hydrants
- Valves and components of valves specified are as defined in BS EN 736-1 and BS EN 736-2.
- Testing of valves
 - Pressure test metallic valves at manufacturer's works, in accordance with BS EN 12266-1 or BS ISO 5208 in conjunction with given specific requirements of the valve product or performance standard.
 - Undertake supplementary tests below in accordance with BS EN 12266-2 in conjunction with given specific requirements of the valve product or performance standard
 - Obturator strength
 - Back seat tightness
 - Operability
 - Anti-static design at 12V
 - Anti-static design at 100V
 - Fire tested design
- Flow resistance

211.030 STOP VALVES:

- Service fluid
- Water
- PN to suit system maximum working pressure.
- WRAS approved for water services applications.
- Comply with BS EN 1074-1 and BS EN 1074-2 in addition to the particular valve type standard, for valves for water supply applications carrying water for human consumption.
- Kitemark certified.
- Pipe material
 - To suit copper tube.
 - To suit plastic tube.
 - To suit steel tube.
- Copper alloy globe type stop valves (stop cocks) to BS EN 1213 for potable water supplies
 - Compression ends for copper - reference Y11.2015A
 - Compression ends for plastics - reference Y11.2015B
 - Capillary - reference Y11.2015C
 - Threaded - reference Y11.2015D
- Copper alloy gate valves for general use to BS 5154
 - Screwed to BS EN ISO 228-1, or ISO 7-1 - reference Y11.2020A
 - Compression to BS EN 1254-2 - reference Y11.2020B

- Flanged to BS EN 1092-3 - reference Y11.2020C
- Loose nut/union end - reference Y11.2020D
- Cast iron gate valves for general use to BS EN 1171
 - Grey cast iron flanged to BS EN 1092-2 - reference Y11.2030A
- Copper alloy globe valves for general use to BS 5154
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2040A
 - Flanged to BS EN 1092-3 - reference Y11.2040B
 - Compression to BS EN 1254-2 - reference Y11.2040C
 - Compression to BS EN 1254-3 - reference Y11.2040D
- Cast iron globe valves for general use to BS EN 13789
 - Grey cast iron flanged to BS EN 1092-2 - reference Y11.2050A
- Steel parallel slide for steam and other high temperature / pressure applications to BS EN 1984
 - Reference Y11.2060A
- Steel wedge type gate valve for general use to BS EN 1984
 - Flanged to BS EN 1092-1 - reference Y11.2070A
 - Threaded - reference Y11.2070D
 - Auxiliary connections
- Ball valves
 - Application, standard and material
 - Potable water - copper alloy to BS EN 13828, PN 10 and distribution temperature of 65 °C with occasional excursions up to 90 °C permitted for a period of 1 hour maximum.
 - General purpose heating, cooling and other applications - copper alloy to BS EN 13547.
 - Steam and high temperature / pressure applications - steel to BS ISO 7121 - reference Y11.2160#.
 - Gas - to BS EN 331.
 - Screw driver/key operated
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2080A
 - Compression to BS EN 1254-2 - reference Y11.2080B
 - Lever operated
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2080C
 - Compression to BS EN 1254-2 - reference Y11.2080D
 - Lockshield
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2080E
 - Compression to BS EN 1254-2 - reference Y11.2080F
- Servicing valves, for water services for maintenance of fittings / appliances, copper alloy to BS 6675
 - Handwheel operated
 - Screwed ends - reference Y11.2085A
 - Compression ends - reference Y11.2085B
 - Capillary ends - reference Y11.2085C
 - Lever operated
 - Screwed ends - reference Y11.2085D
 - Compression ends - reference Y11.2085E
 - Capillary ends - reference Y11.2085F
 - Screw driver operated
 - Screwed ends - reference Y11.2085G
 - Compression ends - reference Y11.2085H
 - Capillary ends - reference Y11.2085I
- Butterfly valves for general use to BS EN 593
 - Semi-lugged between flanges to BS EN 1092-2
 - Lever operated - reference Y11.2090A
 - Gear operated - reference Y11.2090B
 - Between mechanical joints
 - Lever operated - reference Y11.2090C
 - Gear operated - reference Y11.2090D

- Fully-lugged to BS EN 593 - reference Y11.2090E
 - Lever operated.
- Gear operated.
- Cast iron gate type for waterworks purposes to relevant parts of BS 5163
- Key operated type A - reference Y11.2110A
- Closed bottom taper plug valves for gas installations for buildings to BS EN 331.

211.040 REGULATING VALVES:

- Service fluid
- Water
- WRAS approved.
- Kitemark certified.
 - Pipe material
- To suit steel tube.

211.050 DOUBLE REGULATING VALVES:

- Service fluid
- Water
- WRAS approved.
- Kitemark certified.
 - Pipe material
 - To suit steel tube.
- Butterfly type to BS EN 593
 - Between flanges to BS EN 1092-2
 - Lever operated - reference Y11.2210A
 - Gear operated - reference Y11.2210B
 - Between mechanical joints
 - Lever operated - reference Y11.2210C
 - Gear operated - reference Y11.2210D
- Globe valves to BS 7350, section 3.1.
 - Copper alloy
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2220A
 - Flanged to BS EN 1092-2 - reference Y11.2220B
 - Cast iron
- Flanged to BS EN 1092-2 - reference Y11.2220C

211.060 FLOW MEASUREMENT VALVES:

- Service fluid
- Water
- WRAS approved.
- Kitemark certified.
 - Pipe material
 - To suit steel tube.
- Flow measurement devices to BS 7350
 - Section 3.2 Type 3
 - Copper alloy
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2230A
 - Flanged to BS EN 1092-3 - reference Y11.2230B
 - Cast iron
 - Flanged to BS EN 1092-2 - reference Y11.2230C
 - Section 3.2 Type 4

- Copper alloy
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2230E
 - Flanged to BS EN 1092-3 - reference Y11.2230F
- Cast iron - reference Y11.2230G
- Variable orifice valve
- Fixed orifice valve

211.080 TEST PLUGS:

- Self sealing test points - reference Y11.2670A
- Valve controlled test points - reference Y11.2670B

211.100 PIPELINE STRAINERS:

- Bronze (Y type)
 - Screwed to relevant parts of BS EN 10226 - reference Y11.2680A
 - Flanged to BS EN 1092-3 - reference Y11.2680B
 - Compression to BS EN 1254-2
Reference Y11.2680C
- Cast iron/ductile iron
 - Y type - flanged to BS EN 1092-2 - reference Y11.2680D
 - Flanged suction diffuser type reference Y11.2680G
 - Cast iron body with ductile iron cover and cast iron guide vanes (PN16)
 - Ductile iron body and cover, and ductile guide vanes (PN25)
- Ductile iron grooved ends
 - Y type - reference Y11.2680E
 - Suction diffuser strainer - reference Y11.2680F

211.120 TUNDISHES:

- Copper - reference Y11.2690A
- Mild steel, galvanized - reference Y11.2690B

211.140 GAUGES:

- Manufacturer and referencet
- General - reference Y11.2700A
 - 150mm black stoved enamel finish
 - Flush panel mounting - reference Y11.2700B
 - Direct mounting - reference Y11.2700C
- 100mm - finish
- Temperature gauges general - reference Y11.2710A
 - Mercury in steel - reference Y11.2710B
 - Vapour pressure to BS EN 13190
 - Direct mounting - reference Y11.2710C
- Pressure and altitude gauges - reference Y11.2720
- Vacuum gauges - reference Y11.2730
- Differential pressure gaugess
 - Hardwood - reference Y11.2750A

211.150 CONTROL VALVES:

- WRAS approved.
- Kitemark certified.

- Ball control valves
 - Open/close - reference Y11.2315A
 - Two way - reference Y11.2315B
 - Three way - reference Y11.2315C

211.170 CHECK VALVES:

- WRAS approved.
- Kitemark certified.
- Service fluid
 - Water. (°C)
- Copper alloy check type to BS 5154
 - Swing type screwed to relevant parts of BS EN 10226 - reference Y11.2320A
 - Swing type flanged to BS EN 1092-3 - reference Y11.2320B
- Steel and cast iron check valves to BS EN 16767
 - Swing check
 - Flanged - reference Y11.2330A
 - Grooved for mechanical joints.
 - Wafer body - reference Y11.2330B
 - Lift check
 - Flanged - reference Y11.2330C
 - Wafer body - reference Y11.2330D
 - Body material
 - Grey cast iron
 - Malleable cast iron
 - SG cast iron
 - Steel
- Wafer flange fitting type
- Reference Y11.2340A
- Steel globe stop and check type to BS EN 13709 - reference Y11.2370#
- Device to prevent contamination of water by backflow to BS EN 14451
 - Combined check and anti-vacuum - reference Y11.2385A
- Anti-back syphonage valve, combined check and anti-vacuum type
 - Reference Y11.2390A
- Anti-back syphonage valve, hose union anti-vacuum type
- Reference Y11.2391A

211.180 WORKMANSHIP:

- Installation - reference Y11.4010
- Location - reference Y11.4020
- Positioning of components
 - Flow/pressure measurement valves - reference Y11.4030
 - Double regulating variable orifice valves - reference Y11.4040
 - Install control ball valves in accordance with manufacturer's recommendations.
 - Control components
 - Reference Y11.4050A
- Provide outlets of vent cocks with discharge pipes.
- Valve stuffing boxes - reference Y11.4070
- Discharge connections
 - Safety and Relief valves - reference Y11.4080A
 - Vent cocks - reference Y11.4080B
 - Air bottles - reference Y11.4080C

- Automatic air vents - reference Y11.4080D
- Expansion devices - reference Y11.4090
- Expansion compensators - reference Y11.4100
- Flexible connections installation - reference Y11.4110
- Terminal unit connections - install hose connections strictly in accordance with manufacturer's instructions.

211.210 DRAIN COCKS:

- WRAS approved.
- Kitemark certified.
- Throughway gland cock type
 - Reference Y11.2440A
- Screwdown to BS 2879, type 1 - reference Y11.2450
- Ball type - reference Y11.2460

211.220 VENT COCKS:

- Ball type - reference Y11.2480
- Three way gland cock type - reference Y11.2490
- Plug valve type
 - Wrench operated - reference Y11.2500A
 - Gear operated - reference Y11.2500B

211.230 AUTOMATIC AIR VENTS:

- Float type
 - Reference Y11.2510A

250.000 THERMAL INSULATION

250.010 GENERAL:

- Comply with work section general clauses reference below
 - Temperature range - reference Y50.1010
 - Standards - reference Y50.1020
 - Materials - reference Y50.1030
 - Pre-insulated equipment - reference Y50.1032
 - Protection applied in situ - reference Y50.1034
 - European classification for reaction to fire performance - reference Y50.1035A
 - European classification for reaction to fire performance - reference Y50.1035#
 - Spread of flame - reference Y50.1050A
 - Spread of flame - reference Y50.1050#
 - Smoke emission characteristics - reference Y50.1055
 - Electrical bonding terminal - reference Y50.1080
- Inspection and testing - reference Y50.1090
- Make good any sections that are cut during inspection for thickness and compliance with specification.
- Insulation thicknesses
 - Reference Y50.2289

250.020 INSTALLER SELECTION:

- Use a contractor specialising in the supply and installation of thermal insulation.
- Use thermal insulation materials supplied by a manufacturer assessed and registered in accordance with BS EN ISO 9001.
- Use thermal insulation materials supplied by a manufacturer assessed and registered in accordance with BS EN ISO 14001.
- Use thermal insulation materials supplied by a manufacturer assessed and registered in accordance with BS OHSAS 18001

250.030 MINERAL WOOL THERMAL INSULATION - PIPEWORK:

- Temperature of fluid in pipes (°C)
- European Classification for Reaction to Fire Performance
 - Reference Y50.1035A
- Spread of flame as BS 476-7
 - Reference Y50.1050A
- Smoke emission characteristics
 - Reference Y50.1055
- Electrical bonding terminal - reference Y50.1080
- Inspection and testing - reference Y50.1090
- Materials
 - Standard - BS EN 14303.
- Thermal conductivity - reference Y50.2010
- Thermal performance life expectancy

251.000 TESTING AND COMMISSIONING OF MECHANICAL SERVICES

251.010 GENERAL:

- Carry out testing and commissioning as specified in section

251.020 SPECIALIST:

- Use a commissioning specialist who is a member of The Commissioning Specialists Association (CSA).
- Or approved equivalent

251.030 STATIC TESTING:

- Carry out air pressure and leakage testing on air ductwork in accordance with specification section covering air ductlines and ancillaries.
- Carry out pressure / leakage testing of builders work air shafts, voids and floor plenums where they are used for supply ventilation - reference Y51.2015
- Pressure testing
 - General - reference Y51.2010
 - Hot and cold water supply systems, water circulating systems (LTHW, MTHW, HTHW, chilled and condenser water) and steam and condense lines - reference Y51.2020
 - Underground pipework
 - Test pre-insulated bonded steel pipe systems for district heating in accordance with BS EN 13941.
 - Test pre-insulated non bonded pipe systems in accordance with the system manufacturer's recommendations.
 - Test pre-insulated bonded flexible pipe systems in accordance with the system manufacturer's recommendations.

- Underground cold water supply mains - reference Y51.2040
- Fire risers - reference Y51.2050
- Refrigerant pipework
 - Strength pressure test - reference Y51.2055A
 - Leak test - reference Y51.2055B
- Deep vacuum test - reference Y51.2055C pressure (not exceeding 0.5 bars) before commencing any flushing or testing with water.
- On completion of all cleaning, flushing and air testing operations, recharge each system with clean water and subject them to sectional hydraulic tests of one and a half times the working pressure.
- There is to be no loss of pressure for a period of not less than 30 minutes for each test.

251.040 COMMISSIONING:

- Commissioning codes - reference Y51.3020

ISO 7-1:1994

Pipe threads where pressure-tight joints are made on the threads. Part 1 Dimensions, tolerances and designation

Briefing & Overview**Bone Marrow Transplant Service, Ward 4b****Queen Elizabeth University Hospital**

The Bone Marrow Transplant (BMT) service transferred from the Beatson West of Scotland Cancer Centre on 06 June 2015.

As part of routine infection control measures for BMT, it was agreed to reintroduce the routine air sample testing in line with the frequency applied at the Beatson.

On 30 June, I was contacted by the Clinical Service Manager to notify me that Microbiology and Infection Control had received the results of the air samples. The air sample measurements were in excess of the recommended standards for a BMT Unit. At a meeting on 01 July, the ICD reported that only 1 of the 24 rooms met the specification; the other rooms has reading in excess of 5000 against an acceptable normal air particle count of 1000 for a BMT area.

It was also noted that the pentamidine treatment room should have negative air pressure however this did not appear to be in place. Dr Peters, ICD, reported that she has asked for copies of the commissioning and validation data but this had not yet been provided to her. The same data has been requested for Theatres, HDU, lobbied rooms and hepa-filter areas and will be provided to Anne and Kevin for the rest of the sites.

With regard to BMT, it was agreed that a potential solution would be to increase the air flow and ventilation to ward 4b. The aim of this being to increase the pascal measurement to between 5–10, and increase the air exchanges in the room to 12 per hour. Accordingly on the evening of 01 July the ventilation system was increased to maximum capacity. A number of other measures were also agreed:

- Move to ensure that the door and room seals are adequately air tight
- Increase the cleaning schedules to twice daily
- Introduce prophylaxis posaconazole to allograft patients (anti-fungal medication)
- Re sample the ward to assess if an improvement had been achieved.

It was agreed that it would be sensible to await the outcome of the re-sampling exercise prior to making any decision about alternative accommodation for the patients.

The group reconvened on 03 July to assess progress from the above.

It was reported that the air exchange rate being achieved was around 6 per hour, still lower than the desired 12. The pascal measurement from the rooms to the corridor was around 5; the lower end of the accepted range. The ICD reported that whilst there had been an improvement in the particle count across 9 rooms, the remainder remained non compliant and out with the accepted normal standard. The ICD also reported that there had been some fungal growth from environmental swabs taken in the unit.

Following clinical debate, it was agreed that on the balance of risk, it would be safer to transfer the patients back to the Beatson West of Scotland Cancer Centre until such times as a permanent solution could be implemented to ward 4b. However, as an evaluation of the Beatson would need to undertaken, the balance of risk suggested that it would be safer to leave the patients at QEUH over the weekend until an assessment of the Beatson could be undertaken on 06 July.

Dr Craig Williams (Lead Infection Control Doctor) returned from leave on 06 and attended the review meetings on 1100 & 1500. Dr Williams concurred with his ICD colleagues and BMT Consultants that it would be clinically appropriate to transfer the patients back to the Beatson until the environmental issues could be resolved.

Dr Williams requested the validation and commissioning results for the BMT Unit and a further engineering view on the hepa-filtration and ventilation issues. Dr Williams briefly reviewed the clinical specification for the unit and stated that it seemed fine from his interpretation. Peter Moir agreed to develop a programme of work and financial plan related to rectifying the function of the unit.

It is proposed for clinical safety, pending ambulance availability and other infrastructure support, that BMT patients and acute leukaemia patients will transfer from the Queen Elizabeth University Hospital on 8th July back to the Beatson West of Scotland Cancer Centre.

This will affect 18 patients

A communication plan will be put in place with patients and their families, press and other stakeholders. It is planned to tell the patients tomorrow once the infrastructure is in place.

Gary Jenkins

Table of Contents

1. Scope of Works
2. Executive Summary
3. Supply & extract flow rates & air change rates
4. Filter Integrity Test
5. Room Pressure Differentials
6. Schematic Layout of Adults Ward 4B
7. Calibration Certificates

Section 1 – Scope of Works

Adults Ward 4B is located on the 4th floor in Queen Elizabeth University Hospital. Adults Ward 4B is supplied by 3 Air Handling Units located on level 3 plant room, just below one level from the department.

Main traverse readings will be taken from both the supply and extract ducts and the inverter readings recorded.

To ensure compliance with SHTM03-01, the following tests will be carried out;

- 1 - Supply volume flow rates from each terminal grille and air change rates calculated.
- 2 – Record room pressures and compare with the Digital Pressure Panel
- 3 – DOP integrity test all supply HEPA filters
- 4 – Provide an electronic validation report

Section 2 – Executive Summary

Recorded the supply volumes and calculated the air change rates, all achieve or are acceptable to the required specification.

The room pressures are above the minimum required limits.

The change of HEPA filters in each individual Isolation Room was carried out and old filters boxed ready for disposal.

The DOP Filter integrity test all HEPA Filters was carried out. All filters achieved an integrity of 99.99% MPPS.

Section 3 – Air Volumes & Air Change Rates

Air Volume Methodology

Objective:

To provide documented evidence to verify the supply air volume rates through individual filter terminals are in accordance with their design volumes.

Prerequisites – Supply and Extract Air Handling Unit maintenance complete.

Test Method

- Micromanometer – calibrated and used in conjunction with Pitot tube to measure air velocity in appropriate ducting, to calculate air volume for Balometer factor.
- The HVAC System(s) is operational and stable.

Methodology:

- Hold the balometer hood over the diffuser/grille face and ensure balometer is set in the correct direction and read off the measured air volume flow rate.

Acceptance Criteria

- Calibration certificates for all test equipment are appended to the report.

Room Air Change Rate Calculation Methodology

Objective

To provide documented evidence to verify the room air change rate to each room within the Area based on measurement of the total supply air volume to the room in accordance with the design specification.

Pre-Requisites

- The tests described in the air volume methodology have been completed.

Methodology

- Insert all supply air volumes into the results table.
- Calculate the total supply air volume to each room by the addition of all supply HEPA filter flow rates within the room.
- Calculate the air change rate per hour for each room using the following equation:

Total volume of all supply terminal HEPA filter flowrates (m³/h)

Volume of the room (m³)

Acceptance Criteria

- All rooms must achieve the minimum number of air change rates specified in the design data.

Section 4 – Filter Integrity Test

Objective

To provide documented evidence to verify that each HEPA filter installation within the HVAC System(s), comprising the filter, seal and housing, does not permit the passage of particulate material in sufficient quantities to compromise the design intent of the filter. This will be achieved by smoke integrity testing.

Prerequisites

- **Aerosol generator** – calibrated to be capable of generating a poly-dispersed aerosol having the size distribution given in PD6609:2000 Annex B, Clause C.2.1.
- **Photometer** – calibrated and suitable for the measurement of mass concentration of airborne particles having the size distribution given in PD6609:2000 Annex B, Clause C.2.1 and having an accuracy of better than $\pm 5\%$ over the range of a five expandable, six decade resolution and a minimum threshold sensitivity $0.0001 \mu\text{g/l}$ and capable of measuring aerosol concentration in the range of 10 to 100mg/m^3 . The photometer shall have a sample flow rate $0.4 \pm 0.05 \text{ l/s}$
- **Sampling probe** - a suitable sampling probe is required which is designed for maximum coverage of isokinetic flow rates.
- **Calibration certificates** – are required for the above and must be appended to the test report.

Methodology

The test will be performed by introducing an aerosol challenge upstream of each HEPA filter and scanning immediately downstream of the filters and support frame.

A test report will be prepared which will include confirmation of the methodology used, results of testing for each filter, whether each test is a **pass** or **fail**, the location of any detected leaks and indication of the position and extent of any repairs and calibration certificates for all test equipment used.

Acceptance Criteria

- Aerosol concentration readings must be $\leq 0.01 \%$ of the upstream concentration within all grade of rooms.
- A test report is prepared which includes confirmation of the methodology used, results of testing for each filter, whether each test is a **pass** or **fail**. If a fail is recorded replace the filter and retest.
- Attach copy of calibration certificates for all test equipment.
-

Section 5 - Room Pressure Differentials

Room Pressure Differential Methodology

Objective

To provide documented evidence to verify the room pressure regime throughout the Cleanroom suite is in accordance with their design values.

Pre-Requisites

All supply and extract volumes are set to client specification

- All LAF unit(s) are operational, where applicable.
- The HVAC System(s) must have been operating normally and continuously for at least 24 hours prior to commencement of the test.
- The tests are to be carried out "unmanned at rest". Ensure that area supervision have been informed to keep personnel out of the area.
- The test operator has been trained to use the test equipment and is wearing appropriate clean area clothing.
- Room pressure alarms/information;
 - High room pressure set at 15Pa
 - Low room pressure alarm set at 5Pa
 - Door open or out of specification alarm is set for a 2 minute period before alarming.
 - Room pressure alarms can be silenced from the button on the digital display set at each room door entry (on the stainless steel plate).

Methodology

- With the Micromanometer properly zeroed, attach the tubing to the positive connection on the instrument, then place the other end of the tubing underneath the room door, with the tubing going into the higher pressured room.
- Record the reading into the appropriate position on the table below.

Calibrated By : K Low

Date of Calibration : 19 September 2017

This is to certify that the above instrument was fully calibrated. Work carried out was in accordance with procedures laid down in BS EN ISO/IEC 17025:2005. The accuracies of the standards used are traceable to National Standards, via UKAS approved laboratories. The copyright of this certificate is owned by IRC Ltd and may not be reproduced except with the prior written approval of the issuing laboratory. The reported expanded uncertainty is based on a standard uncertainty multiplied by a coverage factor k=2 providing a level of confidence of approximately 95%.

Calibration Statement	
The instrument listed on this certificate has been calibrated against standards traceable to NIST or other recognized national metrology institutes, derived from ratio type measurements, or compared to nationally recognized consensus standards. A test uncertainty ratio of 4:1 [k=2, approx. 95% confidence level] was maintained unless otherwise stated. All results contained within this certificate relate only to the item(s) calibrated. Any number of factors may cause the calibrated item to drift out of calibration before the instruments calibration interval has expired. This certificate shall not be reproduced except in full and with written consent of ATI. This unit has been calibrated to the most recent revision of PCL-030-WI.

QEUH – Ward 4b Upgrade Works

Introduction

This documents sets out the works to be carried out to upgrade the 24 bedrooms in the Haemato-oncology Ward (4b) on Level 4 of the Queen Elizabeth University Hospital to achieve between 5 and 10 pascals differential pressure between the bedrooms and the corridors.

Works to be carried out

In order to provide a sealed room, which will assist in achieving the required 5-10 Pascals differential pressure, an MF ceiling will be installed within the 24 bedrooms. The ceiling will be taped filled and painted and sealed at all interfaces with adjoining walls and services. The ensuite rooms currently have a grid and tile type ceiling which will be retained but with the services and tiles silicon sealed .

The current recessed down lighters within the room will be fitted with a diffuser to provide an IP44 rating. On request from the NHS Estates team the diffuser will be sealed using transparent silicon.

The current ventilation system (Air handling unit 31 AHU63 located within Plantroom 31 on Level 3) serving Ward 4b is currently at its maximum performance and achieving approximately 6 air changes per hour. To ensure that there is some additional capacity within the supply unit, the motors, inverter drives (run and standby) and associated electrical supply will be upgraded. This will assist in achieving the desired room differential pressure (5-10pa) and allow for additional resistance as filters degrade. All filters within the AHU will be changed prior to re-commissioning and the AHU and supply duct work re-cleaned.

The current HEPA filters within the supply diffuser housing within the 24 bedrooms will be replaced with new filters.

The users have requested a visual indication of room pressures, to achieve this a magnahelic type analogue differential pressure gauge (as installed in isolation rooms) will be installed at each room.

During the installation process we will carry out a daily “builders” clean to maintain a level of cleanliness and follow this with a sparkle clean prior to commissioning works commencing.

Maintenance Access

At present there are mechanical and electrical services running above the ceiling of the rooms, this is generally, ventilation ductwork, Smoke dampers, heating pipework, duct mounted heating coil, heating controls, domestic water pipework, medical gas pipework, electrical containment, WIFI data point, fire alarm void detector, Nurse call input / output unit. In order to gain access to the maintainable items and items that may need access for fault finding (fire alarm void detector, smoke dampers, heating controls, electrical trunking, duct mounted heating coil, data point) access hatches will be provided in the ceiling. These hatches will be sealed after the works are complete using silicon sealant.

The HEPA filters are installed within the supply air diffuser mounting and can be accessed by removing the diffuser from the room side.

QEUH – Ward 4b Upgrade Works

Commissioning & Validation

On completion of the installation works the commissioning period will commence. The following activities will be carried out:

1. The Air handling Unit and Supply ductwork will be cleaned and swab samples taken for analysis.
2. The AHU filters will be changed
3. The ventilation systems (supply and extract) will be re-commissioned (initially with the existing HEPA filters remaining to avoid any possible degradation during commissioning) and room differential pressures measured to ensure 5-10 pascals are achieved
4. The existing HEPA filters will be changed and challenge tests (DOP) will be carried out on each filter.
5. Room pressures will again be measured and adjusted if required and the magnahelic gauges calibrated.
6. The ward corridor to the non-ward areas (Core C, Core G and Core A corridor) differential pressure will be measured to ensure a positive pressure is achieved.
7. Commissioning results will be collated and uploaded to Zutec

At various agreed stages throughout the process we will invite the NHS Project Team (and other interested parties) to witness the commissioning/ tests etc.

Once the above items have been completed the area will be handed back to the NHS to allow a deep clean and microbiological testing to be carried out.

Pentamidine Treatment Room

The pentamidine treatment room (HOW 004) is currently achieving an air change rate of 10 air changes per hour and is under a negative pressure (-1.5Pa). No further works are proposed for this room.

Notes:
• This drawing is copyright.
• Do not scale dimensions from this drawing.
• All discrepancies on this drawing are to be reported to the architect.
• Do not modify any element of this drawing.
• Use drawing only for purpose(s) issued.

Magnehelic® Gage Models & Ranges

Bezel provides flange for flush mounting in panel.

Clear plastic face is highly resistant to breakage. Provides undistorted viewing of pointer and scale.

Precision litho-printed scale is accurate and easy to read.

Calibrated range spring is flat spring steel. Small amplitude of motion assures consistency and long life. It reacts to pressure on diaphragm. Live length adjustable for calibration.

Red tipped pointer of heat treated aluminum tubing is easy to see. It is rigidly mounted on the helix shaft.

Pointer stops of molded rubber prevent pointer over-travel without damage.

"Wishbone" assembly provides mounting for helix, helix bearings and pointer shaft.

Jeweled bearings are shock-resistant mounted; provide virtually friction-free motion for helix. Motion damped with high viscosity silicone fluid.

Helix is precision made from an alloy of high magnetic permeability. Mounted in jeweled bearings, it turns freely, following the magnetic field to move the pointer across the scale.

Zero adjustment screw is conveniently located in the plastic cover, and is accessible without removing cover. O-ring seal provides pressure tightness.

O-ring seal for cover assures pressure integrity of case.

OVERPRESSURE PROTECTION

Blowout plug is comprised of a rubber plug on the rear which functions as a relief valve by unsealing and venting the gage interior when over pressure reaches approximately 25 psig (1.7 bar). To provide a free path for pressure relief, there are four spacer pads which maintain 0.023" clearance when gage is surface mounted. Do not obstruct the gap created by these pads.

The blowout plug is not used on models above 180" of water pressure, medium or high pressure models, or on gages which require an elastomer other than silicone for the diaphragm.

The blowout plug should not be used as a system overpressure control. High supply pressures may still cause the gage to fail due to over pressurization, resulting in property damage or serious injury. Good engineering practices should be utilized to prevent your system from exceeding the ratings or any component.

Die cast aluminum case is precision made and Iridite-dipped to withstand 168 hour salt spray corrosion test. Exterior finished in baked dark gray hammerfold. One case size is used for all standard pressure options, and for both surface and flush mounting.

Silicone rubber diaphragm with integrally molded O-ring is supported by front and rear plates. It is locked and sealed in position with a sealing plate and retaining ring. Diaphragm motion is restricted to prevent damage due to overpressures.

Samarium Cobalt magnet mounted at one end of range spring rotates helix without mechanical linkages.

VELOCITY AND VOLUMETRIC FLOW UNITS

Scales are available on the Magnehelic® that read in velocity units (FPM, m/s) or volumetric flow units (SCFM, m³/s, m³/h). Stocked velocity units with dual range scales in inches w.c. and feet per minute are shown above. For other ranges contact the factory. When ordering volumetric flow scales please specify the maximum flow rate and its corresponding pressure. Example: 0.5 in w.c. = 16,000 CFM.

ACCESSORIES

A-321, Safety Relief Valve
A-448, 3-piece magnet kit for mounting Magnehelic® gage directly to magnetic surface
A-135, Rubber gasket for panel mounting
A-401, Plastic Carry Case

A-310A 3-Way Vent Valves

In applications where pressure is continuous and the Magnehelic® gage is connected by metal or plastic tubing which cannot be easily removed, we suggest using Dwyer A-310A vent valves to connect gage. Pressure can then be removed to check or re-zero the gage.

5.0

DATA SHEET

Profilex Standard Wall & Ceiling Panel

Specification

Application: Wall and ceilings

Performance: Non-fire rated

Lock: Budget lock

Frame: Picture frame

Door: Flush metal door

Size (mm): 550x550

Product code: 5200115021

Weight (kg): 6

General information

A general purpose, non-fire rated, beaded frame access panel for application in both walls and ceilings, making access to hidden services quick and easy. This panel is widely specified in Gypframe and MF metal systems as well as being suitable for blockwork construction. It is covered by British Gypsum SpecSure® Lifetime Warranty system, which ensures quality and technical support throughout the building life span. Could serve as a base for any bespoke access panel that is required.

Description

The panel is designed to seamlessly fit within plasterboard as well as masonry constructions. Fitted with a budget lock, flush metal face, manufactured in zinc coated mild steel, 1.2mm gauge. It is fitted with a picture frame where the supporting construction has already been built. The panels are factory painted in polyester powder coated RAL 9910 gloss white and the frame remains visible after installation. Powder coat etch primer white available upon request as a bespoke access panel option. Foam dust seal fitted to the front of the frame

Hinge: pin hinge

Door: removable

Dimensions

Panel is manufactured in 3 standard dimensions, further sizes available on request as bespoke access panels.

Standard dimensions are as follows – hinge side stated first (mm):

300 x 300

450 x 450

550 x 550

600 x 600

The 550 x 550 panel is specially designed to fit seamlessly into British Gypsum framed systems, i.e. panel size 550mm x 550mm to fit between 600mm stud centres.

Installation

1. Insert frame into prepared aperture. Ensure the pre-cut hole is 10mm larger all around than the panel size.
2. For large size, heavy panels, take the door off.
3. Using screws, fix the frame into the framework / masonry ensuring:
 - The fixings are made using the pre-prepared holes on all 4 sides of the frame - it helps to prevent cracking.
 - When screwing through the beaded frame flange, ensure that the heads of the screws are below the edge of the frame, spaced at 150mm centres.
4. Replace the door if removed. When the door is shut, ensure the gap between the panel and the door is equal all around.
5. Apply tape directly over where the beaded frame meets the plasterboard (to assist in preventing cracking).
6. Finish with plaster or joint compound
7. Decorate as required.

DATA SHEET

Fire Ratings

All Profilex Access Panels are tested in accordance with BS476: Part22: 1987 or BS EN1634-1: 2000. All tests were carried out at The Building Test Centre at British Gypsum, East Leake.

Below summaries our range and certificates

Panel range	Type of protection	EN / BS	Test number
Non-Fire rated access panels	n/a	n/a	No test required – non fire rated
FR1 Wall panels	Integrity (both directions)	EN	BTC 17168F

FR1 Loft Hatch Panel (Metal Faced)	Integrity	BS	BTC 17469F - Panel 1
FR2 panel	Integrity	BS	BTC 2047F

Maintenance

Profilex Access Panels are designed to be maintenance free. An occasional wipe over to remove any marks on the paintwork finish is sufficient. The piano hinge and lock mechanism may be oiled periodically if required, with a standard metal lubricant, to ensure trouble-free door operation.

Spares

A range of spare and replacement parts are available. Please contact Artex Ltd. at the address shown on this leaflet for details of your nearest stockist.

QEUH – Ward 4b Upgrade Works

Introduction

This documents sets out the works carried out to upgrade the 24 bedrooms in the Haemato-oncology Ward (4b) on Level 4 of the Queen Elizabeth University Hospital to achieve between 5 and 10 pascals differential pressure between the bedrooms and the corridors.

Works carried out

In order to provide a sealed room, an MF plasterboard ceiling has been installed within the 24 bedrooms. The ceiling has been taped and painted and sealed at all interfaces with adjoining walls and services. The en-suite grid and tile ceiling has been retailed but with the services and tiles silicon sealed .

To ensure that the rooms were sufficiently sealed we have carried out room air permeability testing to the parameters set out in SHPN 04-01 Supplement 1.

The recessed down lighters within the room have all been fitted with a diffuser to provide an IP44 rating.

The ventilation (Supply and extract) to the ward bedrooms is provided by Air handling unit 31 AHU63 and the corridor is provided with extract ventilation from extract fan 31-63 EF01 (both the fan and AHU are located within Plantroom 31 on Level 3). In order to provide a more robust ventilation system and to assist in achieving the desired room pressures the AHU supply fans, motors and frequency inverters (duty and standby) were uprated. The ventilation systems have been re-balanced to achieve the room differential pressures (between 5-10Pa) and the pressure from the corridor to the rest of the hospital (positive pressure). The AHU filters were replaced.

The 24 bedrooms are fitted with HEPA filtration in the supply diffusers. A new HEPA filter has been fitted and validated in each room as part of the works. DoP test ports are provided within the ductwork above the ceiling in each room to allow each room HEPA to be tested.

A digital differential pressure monitoring system has been installed within the ward. Sensors have been located above the corridor ceilings linked to air tubes in the rooms and corridor which measure the differential pressure from the room to the corridor with a read out of the pressure displayed on an panel next to the room door. The pressures of all the rooms are displayed on a central panel located at the nurses station. If the pressure in the room drops below 5Pa or above 15pa for more than 2 minutes then an alarm will sound at the room display and at the central display at the nurses station, the audible alarm can be silenced at both the room display and the central display. When the rooms return to within the parameters then the alarms will automatically reset.

Maintenance Access

There are mechanical and electrical services running above the ceiling of the rooms, this is generally, ventilation ductwork, Smoke dampers, heating pipework, duct mounted heating coil, heating controls, domestic water pipework, medical gas pipework, electrical containment, WIFI data point, fire alarm void detector, Nurse call input / output unit. In order to gain access to the maintainable items and items that may need access for fault finding (fire alarm void detector, smoke dampers, heating controls, electrical trunking, duct mounted heating coil, data point) hatches have been provided in the ceiling. These hatches have been sealed using silicon sealant and would need to be re-sealed after they have been opened for access.

QEUH – Ward 4b Upgrade Works

Commissioning & Validation

On completion of the installation works the following commissioning and validation has been carried out:

1. The Air handling Unit and Supply ductwork were cleaned and swab samples taken for analysis.
2. The AHU filters were changed
3. The ventilation systems (supply and extract) were re-commissioned
4. Air Permeability tests were carried out in the 24 rooms.
5. The room to corridor pressures were set and measured
6. The corridor to hospital pressures were measured
7. The room supply HEPA filters have been changed and challenge tests completed (DOP)
8. The new Room differential pressure monitoring system has been commissioned and validated

27th October 2015

Dear Mr Armstrong

**New South Glasgow Hospital –Isolation Room Testing
Adult's Hospital Ward Bed 4B**

I write to confirm the results of the air permeability testing which we have undertaken on the isolation rooms within Ward 4B.

Testing was undertaken to prove compliance with the requirement of HBN 04 Supplement 1 – Isolation Facilities in Acute Settings. This requires that the enclosure have 'an average leakage rate of no more than 1 l/s of air per m³ of envelope volume' at a positive and negative pressure differential of 20Pa. Further, the measured positive and negative leakage rates should be within 5% of each other.

Each test included the entrance lobby and main room. The ceiling mounted air supply and extract grilles were temporarily sealed with tape during the tests. No further temporary sealing was present at the time of the tests. A 'Minneapolis' door fan system was utilised to undertake each test. The fan was installed within the lobby access door to the corridor to each enclosure. A multipoint test in accordance with CIBSE TM23; 2000 was undertaken to ensure maximum accuracy.

Room Pressures to be set between 5Pa and 10Pa target pressure 7Pa $\pm$ 1Pa

Comments:

Above readings were finalised and witnessed by BM's Julie Miller 6th October 2015.

NB: Door seals have been trimmed to achieve room to corridor differential pressures and the required minimum air change rate (standard size rooms air volume design minimum 80l/s and the 3 larger rooms at a minimum air volume 100l/s).

31AHU63 Supply set at 44Hz

31AHU63 Extract set at 30Hz

31-63EF01 Corridor extract set at 70Hz (Set to control room corridor pressure)

Ward 4B corridor pressure is set to external corridors at approximately +10Pa.

Room pressure alarms/information;

- 1) High room pressure set at 15Pa
- 2) Low room pressure alarm set at 5Pa
- 3) Door open or out of specification alarm is set for a 2 minute period before alarming.
- 4) Room pressure alarms can be silenced from the button on the digital display set at each room door entry (on the stainless steel plate).

Report compiled and finalised by Ian McKenzie (H&V)
8th October 2015

CALIBRATION CERTIFICATES

CERTIFICATE OF COMPLIANCE AEROSOL GENERATOR

No G/26262

The Standards used have been calibrated by internal and external procedures traceable to National Standards.
This Aerosol Generator has been tested with Shell Ondina EL Oil.

Date of Calibration: 16-Mar-15	Model	Serial No
Customer H & V Commissioning Services	Vicount 1300	1025732
Address Kilknowe Office		
16 Barrmill Road		
Galston, Ayrshire		
KA4 8HH		
Service Report No 26262		

STANDARDS USED

INSTRUMENT DESCRIPTION	MANUFACTURER	SERIAL No	LAST RECAL	CERT NO
Photometer	Air Techniques	12076	23-Jan-15	26127
Airflow Meter	Kanomax Climomaster	440952	4-Jul-14	640820
Airflow HLF Bench	Gelman Sciences	9436-89	18-Sep-14	25629
Electrical Safety Tester	MicroPAT+	78491386	20-Mar-14	337772
Aerosol Diluter	Air Techniques	11645	3-Dec-14	25929

AEROSOL OUTPUT CONCENTRATION RESULTS

ELECTRICAL SAFETY TEST RESULTS

Inlet Bottle Pressure (PSI)	Oil Flow Valve	Heater Block Temperature (°C)	HLF Bench Airflow (L/min)	Upstream Concentration (µg/L)	Test No: 213
10	-	316	14,375.9	45	Test Mode: Class one
20	-	316	14,375.9	130	Visual: Pass
30	-	316	14,375.9	200	Earth Test: 0.06 Ω
40	-	316	14,375.9	280	Insulation Test: ^19.9 MΩ
50	-	316	14,375.9	350	Load Test: 0.00 KVA
					Leakage Test: 00.1 mA
					FLOW RATE
					ATI TDA-5B
					N/A LPM

CALCULATED RESULTS

Generator Output (g/min) = Upstream Concentration (µg/L) x HLF Bench Airflow (L/min) / 1,000,000

Pressure	Output (g/min)	Pressure	Output (g/min)
10 psi	0.65	50 psi	5.03
20 psi	1.87		
30 psi	2.88		
40 psi	4.03		

Out Of Limit Errors As Found. Comments: None

Calibrated By : C. Moore

Date of Calibration : 27 August 2015

This is to certify that the above instrument was fully calibrated. Work carried out was in accordance with procedures laid down in BS EN ISO/IEC 17025:2005. The accuracies of the standards used are traceable to National Standards, via UKAS approved laboratories. The copyright of this certificate is owned by IRC Ltd and may not be reproduced except with the prior written approval of the issuing laboratory. The reported expanded uncertainty is based on a standard uncertainty multiplied by a coverage factor k=2 providing a level of confidence of approximately 95%.

**CERTIFICATE OF CALIBRATION****CALIBRATION SUMMARY**

UK01-26273

The instrument under test was calibrated against standards which are either traceable to National Standards or are derived by approved ratio techniques. Any number of factors may cause the instrument to drift out of calibration before the calibration interval has expired.

Prepared For: H & V Commissioning Services Limited
Kilknowe Office
16 Barrmill Road
Galston
Ayrshire, KA4 8HH

Service Report No.: UK01- 26273

Make: ATI

Model: TDA-2G

Serial No.: 14086

Date of Calibration: 17-Mar-15

Calibration Due Date: 17-Mar-16

Calibration Procedure: OSL-10015

The instrument complies with the specification at the measured points.

INTRODUCTION

The ventilation ductwork systems have been thoroughly internally cleaned as detailed in this report.

All cleaning has been carried out to B&ES Guide to Good Practice TR19 (2nd Edition) cleanliness verification standards whereby no more than 0.3g dust / m² duct surface may be found using the 15 litre/min Preferred Vacuum Test Method.

We have taken photographs from various locations before and after our works have taken place to demonstrate the hygiene condition of ventilation ductwork systems.

STD78

EXCERPTS FROM WORKPLACE (HEALTH, SAFETY AND WELFARE) REGULATIONS 1992

MAINTENANCE OF WORKPLACE, AND OF EQUIPMENT, DEVICES AND SYSTEMS
Regulation 5

(1) The workplace and the equipment, devices and systems to which this regulation applies shall be maintained (including cleaned as appropriate) in an efficient state, in efficient working order and in good repair.

(2) Where appropriate, the equipment, devices and systems to which this regulation applies shall be subject to a suitable system of maintenance.

(3) The equipment, devices and systems to which this regulation applies are:-

(a) Equipment and devices a fault in which is liable to result in a failure to comply with any of these Regulations; and

(b) Mechanical ventilation systems provided pursuant to regulation 6 (whether or not they include equipment or devices within sub-paragraph (a) of this paragraph).

Approved Code of Practice (Regulation 5)

20. The workplace, and the equipment and devices mentioned in these Regulations, should be maintained in an efficient state, in efficient working order and in good repair. 'Efficient' in this context means efficient from the view of health, safety and welfare (not productivity or economy). If a potentially dangerous defect is discovered, the defect should be rectified immediately or steps should be taken to protect anyone who might be put at risk, for example by preventing access until the work can be carried out or the equipment replaced. Where the defect does not pose a danger but makes the equipment unsuitable for use, for example a sanitary convenience with a defective flushing mechanism, it may be taken out of service until it is repaired or replaced, but if this would result in the number of facilities being less than that required by the Regulations, the defect should be rectified without delay.

21. Steps should be taken to ensure that repair and maintenance work is carried out properly.

22. Regulation 5(2) requires a system of maintenance where appropriate, for certain equipment and devices and for ventilation systems. A suitable system of maintenance involves ensuring that:

(a) regular maintenance (including, as necessary, inspections, testing, adjustment, lubrication and cleaning) is carried out at suitable intervals;

(b) any potentially dangerous defects are remedied, and that access to defective equipment is prevented in the meantime;

(c) regular maintenance and remedial work is carried out properly; and

(d) a suitable record is kept to ensure that the system is properly implemented and to assist in validating maintenance programmes.

VENTILATION

Regulation 6

(1) Effective and suitable provision shall be made to ensure that every enclosed workplace is ventilated by a sufficient quantity of fresh or purified air.

(2) Any plant used for the purpose of complying with paragraph (1) shall include an effective device to give visible or audible warning of any failure of the plant where necessary for reasons of health or safety.

(3) This Regulation shall not apply to any enclosed workplace or part of a workplace which is subject to the provision of:-

(a) section 30 of the Factories Act 1961;

(b) regulations 49 to 52 of the Shipbuilding and Ship-Repairing Regulations 1960;

System Hygienics Ltd recommends that the systems mentioned in our Certificate of Cleanliness be cleaned on at least an annual basis in accordance with the above Loss Prevention Council recommendations.

A specific Risk Assessment, taking account of the likely rate of grease accumulation and other factors, should be carried out to establish the required inspection and cleaning frequency.

SYSTEM HYGIENICS

System Hygienics Ltd, Chancery Red Estate, Polegate, E Sussex, BN26 6JF

(c) regulation 21 of the Construction (General Provisions) Regulations 1961;

(d) regulation 18 of the Docks Regulations 1958.

Approved Code of Practice (Regulation 6)

32. In the case of mechanical ventilation systems which recirculate air, including air-conditioning systems, recirculated air should be adequately filtered to remove impurities. To avoid air becoming unhealthy, purified air should have some fresh air added to it before being recirculated. Systems should therefore be designed with fresh air inlets which should be kept open.

33. Mechanical ventilation systems (including air-conditioning systems) should be regularly and properly cleaned, tested and maintained to ensure that they are kept clean and free from anything which may contaminate the air.

34. The requirement of regulation 6(2) for a device to give warning of breakdown applies only 'where necessary for reasons of health or safety'. It will not apply in most workplaces. It will, however, apply to 'dilution ventilation' systems used to reduce concentration of dust or fumes in the atmosphere, and to any other situation where a breakdown in the ventilation system would be likely to result in harm to workers.

35. Regulation 6 covers general workplace ventilation, not local exhaust ventilation for controlling employees' exposure to asbestos, lead, ionising radiations or other substances hazardous to health. There are other health and safety regulations and approved codes of practice on the control of such substances.

EXCERPTS FROM HVCA GUIDE TO GOOD PRACTICE TR19
'Cleanliness of Ventilation Systems'

Section 9 - Verification of Cleanliness

9.1 The primary method of assessment is visual. For cleaned system verification the surface should be visibly clean and capable of meeting the level of cleanliness specified.

9.2 Verification where specified on general ventilation systems, should be by means of a vacuum test (VT), as described in Appendix D, based on the recommendations of the US National Air Duct Cleaners Association (NADCA) ACR 2005. A system will be considered acceptably cleaned if, following a VT, a result of not more than 0.75g/m² is achieved. This is equivalent to 0.75mg/100cm² as per ACR 2005.

9.3 It should be noted that verification should take place immediately after cleaning to avoid any possibility of post-clean interference. The client should be given the opportunity to witness testing of ductwork surfaces.

Section 5.2

A testing procedure is defined in this guide which may be used to establish whether or not it would be appropriate to clean a mechanical ventilation system. This provides one reasonable practicable way of satisfying the Regulation and ACRs relevant to the cleanliness of ventilation systems.

Section 5.5

The owner or operator should select the type(s) of test(s) and frequency to be included within their testing regime to suit the particular requirements of the building served by the ventilation system. The regime should be reviewed regularly (eg. annually), to take into account any changes in the building use, legislation and/or health and safety guidance.

Section A8

The specification should include a definition of the method of verifying the effectiveness of the treatment including the number and type of microbiological samples to be taken and their analysis eg. in-house or third-party laboratory.

WORK CARRIED OUT

The 24 rooms, numbered 76 to 99, each have a CMR V-Sensors installed in the ceiling outside the room with a wall mounted pressure display in the corridor. There is also a HMI (Touchscreen) display at the Nurse Station.

Each of the 24 no. sensors and displays had their wiring checked. They were then powered up and then the pressure readings checked to the corridor displays and the HMI at the Nurse Station. All units were confirmed as operating and reading correctly.

The operation of the Pressure Alarms, on each room, were checked and the Alarms confirmed at the corridor displays and the HMI at the Nurse Station. Each Alarm was acknowledged/silenced from the corridor display or the HMI.

The pressure readings displayed were confirmed by the H&V Engineers on site during the commissioning.

Since 1978

System Description

The area consists of 24No. Rooms which require pressure monitoring.

A V-Sensor Air Pressure Monitor will be mounted in the ceiling local to each room. A Blue PVC Tube will be connected to an Air Probe Plate on the ceiling/wall of the reference area, and a Red PVC Tube will be connected to an Air Probe Plate on the ceiling/wall of the room. A local DIS-125 Alarm Display Plate will be mounted on the wall to provide a pressure readout and audible / visual alarm, and be connected to the V-Sensor using Lapp DeviceNET Thin Cable. The V-Sensor will be wired to a Modbus Tap (Power / Communication Junction Box) using the same Lapp DeviceNET Thin Cable. The 24No. Modbus Taps will be connected together using DeviceNET Thick Cable, which will be taken back to the Nurse Station Panel.

The Nurse Station Panel will be a Stainless Steel surface mount box housing a 230Vac - 24Vdc power supply, which will feed the V-Sensors and a 7" Colour HMI. The Modbus RTU from the V-Sensors shall be read in and provide a display of the measured Room Pressures. Each differential pressure value will be displayed in Pa (Pascals) and sit within a Box which shall be Green when Healthy, changing to Flashing Red if in Alarm. When in Alarm the HMI will have a common Audible Alarm Sounder which may be silenced by pressing the Mute Button on the touch screen. When muted the Red Box will cease flashing and become static, before returning to static Green when the fault is rectified. This functionality essentially replicates that of the V-Sensor / DIS-125 Alarm Display Plate, so that any alarm can be acknowledged locally or at the Nurse Station.

The V-Sensor has integral adjustments to allow the setting of both high and low pressure alarms, along with delay timers to prevent nuisance alarms when the areas are being accessed during normal activities.

The proposed system is an instantaneous display only, and does not offer any data retention.

QEUEH Ward 4b Room Pressure Monitoring Panel Operating Instructions

NORMAL OPERATION

The main screen on the HMI shows 24 boxes which display the pressures for each room. If the condition of the room is healthy, the border of the box will be green.

If a room goes into alarm, the border for the pressure display for that room will flash red and the HMI alarm will sound. The alarm can be muted by pressing the box which is flashing. The border will then stop flashing and will show steady red until the room comes out of alarm. Pressing the button in the lower left corner of the screen will mute all alarms. The alarm sounder in the display plate outside the room will be muted when the alarm is muted from the panel.

The main screen is the only screen used for normal operation. It is possible to swipe the display left or right to show other screens but these will be locked unless a higher level user is logged in. If a user swipes to a different screen then they will need to swipe back to the normal screen.

ADVANCED OPERATION

Normally there is no user logged in and muting of alarms is the only function available. To access higher level functions, an Engineer or Administrator will need to be logged in. In practice it is unlikely that access to higher level functions will ever be needed.

Users

Engineers can mute alarms, change alarm settings and exit or restart the application. An Engineer "cmreng" with a password 287099 was configured at the factory.

Administrators can, in addition, create other users. An Administrator "cmradmin" with a password 287222 was configured at the factory.

To login, press the Login button and then enter the password. The username is not entered and is determined from the password. If the login was successful, the name of the user will be displayed briefly. Automatic logout will occur after a few minutes.

Alarm Settings

The alarm thresholds and timer may be changed by an Engineer or Administrator. These settings are stored in the sensors but can be modified using the HMI. On the main screen, touching a pressure box to the left or right of its central point will open a window showing the alarm thresholds in Pa and the alarm time in seconds. The settings can be changed on this screen. It is recommended to close the alarm settings screen then open it again to make sure the sensor has been updated with the changes.

Restarting the HMI

The HMI can be restarted by pressing the CMR logo. Open and close Control Panel and then press the Launch Application button.

User Administration

Administrators can create, modify and delete users by pressing the Admin button. This opens the Administration screen. Operation is self explanatory. **It is important not to delete the only administrator.** If there are no administrators left then it will be impossible to do any further user administration.

V-SENSOR AIR PRESSURE AIR VOLUME

- Ultra low pressure and volume measurement
- Traceable Calibration Certificate is Included
- High accuracy and repeatability
- Linear pressure or air volume output
- Both measurement and PID control output
- Two modbus for monitoring and remote display
- One alarm relay, buzzer and LED indicators
- Auto Zero and overload protection is standard
- Operator keyboard display for all functions
- Two Modbus rtu, 0..10V and 4..20mA outputs
- IP65 enclosure with easy mount wall bracket
- 24 month warranty
- 30 Years field application experience

V-SENSOR Wall Mount with Keyboard and LED display

GENERAL

The V-Sensor is a wall mount ultra low pressure transmitter which provides 0..10V and 4..20mA as well as Modbus communication over the selected range. The display can be adjusted via the keyboard to show the measured value in Pa, hPa, kPa, m/s, l/s, m³/s, m³/h and ACR (air change rate).

A PID control output can be selected, but still having one output for monitoring the pressure or volume.

The pressure ranges can be adjusted via the keyboard, but the base range is factory calibrated and certified i.e. 10, 25, 50, 100, 250 and going up to 7500 Pa. All ranges can be adjusted to +/- i.e. +/-25Pa.

Power supply 24Vdc/ac non-isolated or 24, 110 and 230Vac Isolated are available as standard.

CMR TRANSDUCER

The transducer is manufactured by CMR with high precision engineered components. The principle is the measurement of the displacement of the diaphragm by means of a push and pull variable reluctance circuit which is not effected by humidity and hence it can be used in any industrial or commercial environment. There are no mechanical connections to any of the sensing coils and the diaphragm.

CMR Transducer

Extremely low pressures can be measured with excellent repeatability and minimal hysteresis. The diaphragm displacement is so small that no air volume is required to measure the air pressure which means measurement tubing can be connected in excess of 200m throughout the building without losing accuracy or measurement speed.

The zero drift is minimized by the measuring copper coils which are matched to provide excellent self compensation. One coil measures positive and the other negative drift and therefore balances any excessive drift between two tolerance limits in its life cycle. The CMR Transducer has a proven field track record of over 30 years. All CMR Sensors are temperature compensated in a computerised climate chamber.

CMR Climate Chamber

KEYBOARD DISPLAY

A combined keyboard and LED Display is fitted into the lid and is connected to the V-Sensor board with a plug-in ribbon cable. All parameters can be accessed via the key pad. The display can also be programmed to switch off after a time and by touching a key to light up again. Normally it is always on.

PARAMETER CONFIGURATION

The duct width and height can be entered as well as the density and (mf) magnification (K) factors to scale Fan Inlet Rings, Flowgrids, Veloprobes, Oval Flowprobes, Venturis or any other velocity pressure producing probes. The volume can be linearized over 8 points to provide extremely high accuracy in measurement.

The range can be changed from -10 Pa to 30 Pa or -20 to 120 Pa. The output signals can be changed to i.e. 2..10V, 1..5V or 5..19mA. The V-Sensor has a configurable Volt Free alarm output relay.

The auto zero function is built in, which is of great advantage at very low velocity pressure measurement i.e. 0.3 Pa to have an accurate base point at all times. The auto zero can be turned off where it is not required.

The overload protection can be switched on and is ideal to protect the low pressure diaphragm. It is active whenever the sensor is powered up.

One of the outputs can be configured to be a PID control to drive fan inverters or modulating dampers and the other can be used for the actual pressure or air volume measurement for the BMS or PLC system. The set point can be sent from the BMS via modbus.

The signals can be individually smoothed. The control output can be fast but the measurement output can be dampened.

A calibration mode can be selected so that all of the parameters remain the same as commissioned and only the base sensor shall be calibrated and displayed in Pa.

MODBUS RTU COMMUNICATION

The modbus communication can be used to read and write all parameters by the remote Host which can be the BMS, PLC or PC.

REMOTE ALARM DISPLAY

A remote display DIS110 without alarm or DIS125 with alarm and mute button can be connected via Modbus if the modbus is not used for the BMS. The alarm button has green and red Led light rings to show healthy or alarm status. A buzzer is also fitted. A separate power supply can be wired to the display.

V-SENSOR PRESSURE APPLICATIONS

ROOM PRESSURE MEASUREMENT WITH CMR V-SENSORS

Tubes + Fittings

Ceiling Air Probe

Air Probe Plate

DIS 110 Display

DIS 125 Display

LED 225 Display

The above schematic shows a typical clean room. The room pressures are measured in cascades starting in Room 3 from a reference such as a plant room or any other stable location, then measuring across to room 2 and finally across to Room 1.

Each room has an air probe plate fitted to the ceiling. The air probes are connected to the V-Sensors with red and blue CMR PVC Tubing.

The CMR PVC tubing can be run up to 200m from the room to the P-Sensor without losing accuracy of the measurement.

Remote LED display plates are fitted for the operators to see the actual room pressure in Room 1 and 2. Room 2 has also a local illuminated alarm green and red led built as ring into the mute button and a buzzer. Room 3 has only a modbus alarm led indicator plate.

The V-Sensor is a true Low Differential Air Pressure Transmitter and can be used for static pressure, vacuum pressure and differential pressure measurements in positive or negative areas.

The operator keyboard with LED display is fitted into the lid as standard and shall display the actual pressure. All parameters can be adjusted without opening the lid.

The Pressure measurement can be transmitted via modbus rtu or analogue signals 0..10V or 4..20mA to the SCADA, BMS or Industrial PLC systems for long term monitoring.

All future calibration can be done using the calibration mode. Calibration Certificates traceable to National and International Standards (UKAS) are supplied as standard with all V-Sensors.

Issue V-GB-04-2

V-SENSOR AIR VOLUME APPLICATIONS

VELOCITY PRESSURE AND AIR VOLUME MEASUREMENT WITH CMR V-SENSORS

FGG Flowgrid

VVM Venturi

PVC Tube Fittings

CMR Veloprobes

Duct Probes

Oval Flowprobe

The CMR V-Sensor is an ultra low high precision Velocity Pressure Transmitter which has been designed to accurately measure air volumes in Ventilation Ducts. The built in Square Root Extraction and Magnification Factor Scaling makes the V-Sensor an extremely versatile measurement instrument.

It can display the actual volume in m³/s. Other Units such as m³/h, litres/s or ACR (Air change rate) can be selected via the keyboard. Any Imperial measurement units i.e. CFM are available on request.

The CMR PVC tubing can be run up to 200m from the sensing station to the V-Sensor without losing the accuracy of the measurement.

The V-Sensor is used for monitoring and also controlling Volume Flow in Commercial or Process Applications and is designed to be connected to any CMR Veloprobes, Duct Probes, Flowgrids, Venturis and Fan Inlet Rings. It can also be used with any existing or custom made duct Flow Measurement Device.

The measured values can be transmitted to remote display plates, SCADA, BMS control systems or Industrial PLCs through the output signals of 0...10V, 4...20mA, modbus 1 and 2.

Calibration Certificates traceable to National and International Standards (UKAS) are supplied with all V-Sensors.

Issue V-GB-04-2

V-SENSOR VELOPROBE MEASUREMENT

GENERAL

The drawing shows a typical application for CMR Veloprobes and V-Sensors.

The supply air duct can either be fitted with one central Veloprobe or individual Veloprobes on each of its branches.

In many cases, the positions of the Veloprobes are very much dictated by the design of the building. The CMR Veloprobe can be fitted in almost any position in order to provide accurate measurements.

In a single supply and extract duct application, the V-Sensor measures the building's actual total supply and return volumes. As both V-Sensors are calibrated to provide a linear air volume signal, tracking of supply and extract air is now made easy.

The duct height, width or diameter, density and magnification ('K' factors) can be entered in the V-Sensor via the keyboard very easily and only the measurement range for 0..10V or 4..20mA must be given to the BMS at final commissioning.

For multiple duct applications, the total supply and extract air volume is derived by adding all air volumes from the individual ducts.

Example of Volume adding: $S = E \pm \text{an offset for positive or negative building pressure}$
 $S1 + S2 + S3 = E1 + E2 \pm \text{offset}$ or $S = E1 + E2 \pm \text{offset} - \text{etc}$

V-Sensor - scaling in m/s only.

Adjust the Impact Veloprobe (red) to face the Airflow and and adjust the Static Veloprobe (blue) to approx. 180° away from the airflow.

Scaling of the duct height and width is done in the BMS

Use the keyboard and adjust the display to m/s. Adjust the height and width to 1 and adjust the (mf) to 2.000. Press the very left hand key briefly and the sensor range is displayed for a short time, which is the range at 10V in m/s. If the range of the sensor is 100Pa then it should display 9.128 m/s.

Take a Pitot Tube reading in the duct and if the velocity is not equal to the display then adjust the magnification factor until it is equal then press the range key again to get the new range in m/s.

V-Sensor - scaling in m3/s - m3/h - l/s - ACR air change rate

Adjust the Impact Veloprobe (red) to face the Airflow and and adjust the Static Veloprobe (blue) to approx. 180° away from the airflow.

Scaling the range for the BMS

Use the keyboard and enter the duct height and width or simply enter the width of a round duct and keep the height at 0. Adjust the magnification factor (mf) to 2.000. Use the display key and select m3/s, m3/h, l/s or ACR (Air Change Rate) and adjust the decimal places. When pressing the left hand key the sensor range shall be displayed in the selected units at 10V. Take a Pitot Tube reading in the duct and if the volume is not equal to the display then adjust the magnification factor until it is equal then press the range key again to get the new range.

V-Sensor air volume measurement with Veloprobes in Duct

V-SENSOR

KEYBOARD FUNCTIONS

FUNCTIONS (Use Operator Manual for full Instructions)

The V-Sensor LED-Keyboard has been designed to simplify installation and commissioning. The only time the lid must be opened is for wiring during installation. Thereafter every control function can be accessed via the keyboard, even the calibration can be carried out utilising this functionality.

ZERO KEY

When pressing the zero key for 1 seconds, the V-Sensor shall perform a zero which means the pressure is taken off the sensor internally and the diaphragm is relaxed to zero.

PASSWORD

The keyboard can be password protected so that only the display can be operated, but no adjustments can be made.

RANGE KEY

Pressing the range key very quickly once will display the sensor range i.e. If it shows 100, this means the range of the sensor has been configured to 0-100Pa for 10V/20mA output. By pressing the range key for 1 seconds it enters the configuration menu:

S	Software Version	1.5
Ad	Network Address	1-254 (0 Denotes Modbus Display)
AZ	Auto Zero	on-off
P	Positive Range	i.e. + 25
n	Negative Range	i.e. - 25
Opp	Over Pressure	1(on) 0(off)
F	Zero Offset	
t	Set Point	
Sn	Modbus smoothing	doro
Adj	Internal/External	I or E
Azt	Auto Zero time Interval	1-99h
FF	Modbus float format	0-3

OUTPUT KEY

Pressing the output key very quickly once will display the sensor output configuration i.e. lin or root, which means the sensor measures pressure or airflow. By pressing the output key for 1 seconds the configuration menu can be reached:

So	Output Smoothing	0-99
Lin	Output mode	linear pressure
root	Output mode	square root
e	Output scaling	F, L or Fac
F	Mag Factor	0-99.99
	Duct width	0-9999mm
I	Duct height	0-9999mm
d	Air Density Factor	0-9.99kg/m3
r	Room Size	0-9999m3
s	Small Value Shut off	0-99.99%
o	Output Re-Scaling	
bFl	Bi-Directional Flow	0 or 1

DISPLAY KEY

Pressing the display key very quickly once will display the measurement units. i.e. Pa, hPa, kPa etc, and is the units the sensor has been configured to i.e. Pa. By pressing the display key for 1 seconds it enters the configuration menu:

Sd	Display Smoothing	0-99
Pa	Pascals	
hpa	hecto Pascals	
kpa	kPa	
nnps	metres per second	
lps	litres per second	
nn3s	cubic metres per second	
nn3h	cubic metres per hour	
acr	Air Change Rate per hour	
dp	Decimal Place	0-4
pos	Display polarity (+)	
neg	Display polarity (-)	
Led	Display Activation	1 or 0
L2b	Leading Zero Blanking	1-4

V-SENSOR STANDARD LED KEYBOARD

ALARM KEY

Pressing the alarm key quickly shall mute the alarm as the V-Sensor has an alarm buzzer built in.

By pressing the alarm key for 1 seconds it enters the configuration menu:

L	Low Alarm	
H	High Alarm	
t	Alarm timer 1	0-999
t	Alarm timer 2	0-999
u	Units	dU (Display Units) or Per (%)
af	Alarm Function	0-2
Sr	Self Reset	0-1
rb	Remote Buzzer	-, 0, 1 or P
rA	Remote Alarm Indication	-, 0, F or LH
rt	Re-alarm timer	0-999 minutes
tU	Alarm timer units	s or h

UP-DOWN KEY

The up and down keys are used to select the various parameters

OUTPUT SIGNAL

0-10V and 4-20mA are also available on J7.

V-SENSOR

ORDER DESCRIPTION

GENERAL

CMR manufactures the V-Sensors to suit many low pressure and volume measurement applications. Because of the variety of pressure ranges, output signals and power supplies it has been necessary to design an easy to use selection table for anybody to make up a V-Sensor specification to satisfy a requirement. On the V-Sensor Selection Table you will find all specifications available with the associated ordering code.

V-SENSOR BASE PART NUMBER

The V-Sensor Part Number starts with a base part number of the type of sensor. Code '24' which is a V-Sensor in a standard ABS enclosure.

The Part Number therefore starts with '24'.

V-SENSOR ISSUE No

The V-Sensor will have a version number to identify the model. The Code is '1' for version '1'.

The Part Number extends to '241'.

TUBE CONNECTORS

6 mm barbed nipples to fit CMR PVC Tube are fitted as standard into the ABS box. They have the Code 'A'.

4 mm barbed nipples to suit the CMR Silicone Tube are also available as Code 'B'.

The example has 6 mm barbed nipples which is standard.

The Part Number therefore extends to '241A'.

NEGATIVE PRESSURE RANGE

The Negative Range is specified as (-). If the application requires to measure a negative pressure against a reference, i.e. a room has to be at negative pressure compared with the corridor then the room has to be connected to the Red or (+) nipple. The blue (-) nipple shall be connected to the reference in this case the corridor.

The negative room pressure shall suck on the red (+) nipple and the V-Sensor produces an output signal equivalent of the negative pressure measured.

In the Example we have chosen -25 which has the Code '0025'.

The Part Number extends to '241A0025'.

If the V-Sensor must only measure in the positive Range i.e. 0-25 then the Negative Range will always be selected as 0 and the Code is always '0000'.

PRESSURE UNITS

The negative pressure and the positive pressure range must be expressed in units i.e. Pa or kPa. The CMR transducers are in Pascals (Pa) as standard.

In the example Pa was selected with Code 'P'.

The Part Number extends to '241A0025P'.

POSITIVE PRESSURE RANGE

To measure Positive Pressure against a reference it is necessary to select a positive range i.e. +25. The Code is '0025'. This means the V-Sensor selected above can measure from -25 Pa to 0 and from 0 to +25 Pa. The output Voltage would therefore be 5V or 12mA at 0 Pa.

The Part Number extends to '241A0025P0025'.

LABEL UNITS

As the V-Sensor has a fixed label next to the LED display, i.e. Pa, kPa, hPa, mB etc. It is necessary to specify the label when selecting the part number as this is all part of the validation of the instrument.

In the example Code 'P' for Pa was selected.

The Part Number extends to '241A0025P0025P'.

OUTPUT SIGNAL

The Industry Standards for Output Signals are 0-10V or 4-20mA, but other signals can be adjusted via the keyboard by the operator.

If 0-10V is the Output Signal for -25 Pa to +25 Pa then 5 V is 0 Pa. From 5V to 0V the V-Sensor measures from 0 Pa to -25 Pa i.e. (-)12.5 Pa would be 2.5V.

From 5V to 10V the V-Sensor would measure positive Pressure from 0 Pa to +25 Pa i.e. +12.5 Pa would be 7.5V.

It is standard to use equal ranges -25 Pa to +25 Pa rather than -25 Pa to +50 Pa but the V-Sensor can be adjusted via the keyboard to provide this off-set.

In the Example, we have selected Dual (0-10V & 4-20mA) which has the Code '1'.

The Part Number extends to '241A0025P0025P1'.

POWER SUPPLY

CMR can supply 24Vdc/24Vac Non-Isolated which does not have an isolation transformer, and is also suitable for 3-Wire connection. Most common is the 24Vac Isolated, 110Vac and 230Vac are less used, but also selectable. In the example we have selected 24Vac Isolated which has the Code '3'.

The Part Number extends to '241A0025P0025P13'.

FINAL PART NUMBER

The Part Number to order is '241A0025P0025P13'.

Now try and select your own V-Sensor using the V-Sensor Order Selection Table.

V-SENSOR TECHNICAL SPECIFICATION

Measurement Range	Any Range from 0-25Pa or -/+25Pa up to 0-7500Pa or -/+7500Pa
Overload Capacity	Ranges 25Pa - 150Pa up to max 1200Pa if over pressure protection is off.
	Ranges from 200Pa - 7500Pa up to max 10 times of range if over pressure protection is off.
Media	Non corrosive gases such as Air, N ₂ , O ₂ , CO ₂ , N ₂ O and inert gases
Diaphragm Unit	Beryllium Copper suitable for high concentration of Formaldehyde - Stainless Steel on request.
AC Power Supplies	24 Vac 50/60Hz 198mA. Internal Fuse 300mA Auto-Reset.
Transformer Isolated	110Vac 50/60Hz 40mA. Fuse 315mA Wickmann.
	230Vac 50/60Hz 20mA. Fuse 315mA Wickmann.
DC Power Supplies	24 Vdc (19 to 31Vdc) smoothed 118mA Internal Fuse 300mA Auto-Reset.
Voltage Output Signal	0-10V (0 to 100% of Range) RL = 5kOhm min.
	Other output signals (e.g. 2-10V) or PID loop control is programmable via the keyboard.
Current Output Signal	4-20mA (0 to 100% of Range) RL = 500 Ohm max. (0-20mA) or PID control is programmable via keyboard
Relay Output 1A 24Vdc	One Alarm changer over volt free contact is user programmable
2 x Modbus rtu Connection	2 x Output Signal, Alarm Status, Alarm Thresholds and Alarm Timers are all readable as Modbus rtu Commands. Modbus register assignments to read and write are available in user manual.
Hysteresis/Repeatability	0.1% Typical of Full Scale.
Linearity (Accuracy)	+/- 0.25% of Full scale = > 100 Pa and 0.25Pa < 100Pa.
Zero Drift	0.05%K (+10°C to +50°C) - Automatically corrected to 0.0 if Auto-Zero function is enabled.
Operating Temperature	-10°C to +70°C.
Mounting Position	Vertical.
Weight	0.6 kg In ABS Housing.
Electrical Connections	ABS Housing: 1 x M20 Gland and 1 x M12 Gland and internal removable Screw Terminals.
Air Tube Connections	ABS Housing: Positive and Negative Pressure Barbed Nipple 6mm OD x 15mm long for CMR PVC Tube
	Alternatively Barbed Nipple 4mm OD x 15mm long for silicone tube on special request.
Enclosure	Plastic (ABS) Light Grey (RAL7035) - Protection IP65.
	EN61326-1 EMC - EN61010-1 SAFETY.
Calibration Certificate	Supplied with Certificate traceable to national and International Standards (UKAS).

NOTES

NEW SOUTH GLASGOW HOSPITAL AND LABORATORY PROJECT

HAEMATO-ONCOLOGY WARD BRIEFING PAPER

January 2012

The purpose of this paper is to give a brief overview of the facilities, design principles and further work required for the Haemato-oncology Ward.

1.0 LOCATION AND CO-LOCATIONS

The Haemato-oncology Ward is located at the bottom of the ward stack, which is the fourth floor of the hospital. The Haemato-oncology Ward shares the floor with Renal Wards. (Please see Appendix 1)

There is rapid access to Theatres (second floor) Critical Care (first floor), Imaging (first floor) and Emergency Department (ground floor) through the central patient beds lifts.

2.0 SERVICES

The Haemato-oncology Ward will provide an inpatient service to patients with a range of malignant and non-malignant haematology conditions. A high proportion of patients are immunocompromised making them vulnerable to infection.

3.0 AGREED PHYSICAL LAYOUT

The bedrooms are sealed with hepafiltration positive to the rest of the hospital and all highly filtered air to H13, i.e. 99.95% as requested by infection control.

The ward has:

Clinical rooms

- 10 single beds, all ensuite with shower and toilet.
- Two treatment rooms located near the main ward entrance as follows:
 - Pentamidine Treatment Room (negatively pressured for the administration of pentamidine inhalations)
 - Intrathecal Treatment Room

Support rooms

- Reception/staff base
- Relatives Room
- Socialisation Space

- Clean Utility
- Dirty Utility
- Pantry
- Equipment Store
- Hot Desks/Charge Nurse Office

Please see Appendix 2 for the 1:200 departmental drawing.

(N.B. the Haemato-oncology Ward was originally planned as a 14 bedded ward with 4 day beds, but was then revised in February 2010 to 10 inpatient beds. The area of the ward is highlighted in orange and finishes at the Large Equipment Store, room HOW32. (The ward area is shown in orange in Appendix 2.)

Design Principles

- As with the generic wards the bedrooms all face outwards with individual views and large picture windows to maximise the light into the rooms.
- Large vision panels from the ward corridors into the bedrooms to maximise patient observation and enable patients to see the staff.
- Minimal travel distances for staff, the immediately required Support Services being located down the middle of the Ward.
- The Ward has a central Staff Base and two Nurse Touch Downs to allow a 'devolved' nursing model whereby, rather than working from one central staff base, nursing teams will be assigned to clusters of bedrooms supported by the touchdown spaces.
- Support Services, which will be shared by the 4 wards on each floor, are located in a central core between the wards, these include 6 Hot Desks, a Medicines Management Workspace, Staff Change and a Facilities Management Kitchen. On the fourth floor there is also a large Seminar Room which will be available to all GG&C staff, bookings will be undertaken centrally through Facilities Management.
- Hoists – there will be overhead hoists in two rooms these being: HOW 017 & HOW 024.
- In order to avoid visitors to renal walking through the haemato-oncology bedroom area an additional access route has been created.

Security

There will be audio visual security access to the ward - Staff will access the ward with a security access swipe card.

The Clean Utility will have a keypad entry so the door will remain closed to ensure only staff enter this area.

IT

The hospital is wireless enabled.

There are 2 x double data points and 6 x double electrical sockets at each bed. Where appropriate, IT points have been incorporated to allow barcode tracking of stock.

Pharmacy

Patient specific medication will be stored in the Patients Own Drugs (POD) storage unit within the bedroom area.

Pharmacists will work in teams from the Medicines Management Rooms attached to ward areas to support the 'My Medicines' model of care.

4.0 AREAS OF FURTHER WORK

An operational policy is required for the ward.

QUEEN ELIZABETH UNIVERSITY HOSPITAL

ADULTS – RENAL WARD 4C

Section 1 – Scope of Works

Adults - Ward 4C is located on the 4th floor in Queen Elizabeth University Hospital.

Adults Ward 4C is supplied by 3 Air Handling Units located on level 12 plant room, just one level below from the department.

To ensure compliance with the SHTM03-01, the following tests will be carried out;

- 1) Record room differential pressures. Room to Corridor and room to en-suite.
- 2) Record supply air volumes and calculate room air change rates.
- 3) Record Extract air volumes and calculate en-suite air change rates.

QUEEN ELIZABETH UNIVERSITY HOSPITAL

ADULTS – RENAL WARD 4C

Section 2 – Definition of terms

Assessment of compliance with SHPN 04 Supplement 1

Poor

Air volumes and hence air-change rate is less than 75% of the design. Room pressure differentials do not ensure a flow from clean to less clean areas; supply or extract air diffusers are not clean; pressure stabilisers not clean and/or not operating correctly; visible faults in the fabric of the suite; doors unable to close completely; general air of neglect.

Action: Urgent management action required.

Average

Air volumes and room pressure differentials approximate to the original design values; supply air diffusers clean but extracts visibly fouled; most pressure stabilisers clean and operating correctly; minor faults in the fabric and décor of the suite.

Action: Maintenance action required.

Good

Better than average.

Action: None.

Maintenance quality

Poor

More than three answers are negative.

Action: Management action required by estates/facilities department.

Average

No more than three answers are negative

Action: Maintenance action required.

Good

No answers are negative.

Action: None.

QUEEN ELIZABETH UNIVERSITY HOSPITAL

ADULTS – RENAL WARD 4C

Section 3 – Executive Summary

All rooms within Adults - Ward 4C comply with the client's specification.

Derogated client's specification:

- 1) Room ACRs = 3AC/HR
- 2) En-suite ACRs = 6AC/HR
- 3) Room Differential pressures to corridor to be nominally positive (+ve)
- 4) En-suite toilet to be -ve to the room.

CVG (Ceiling Ventilation Grilles x10) removed and replaced with a standard ceiling tile.

Total area of Ward 4C is 955.8m³.

Pressure across door exiting 4C at Core K is was +2.4Pa and across the door at Core A being +1Pa.

Notes:

Equipment:

The instrument detailed above has been calibrated against equipment serial number 0047368 which in turn has been calibrated against instruments and equipment that are traceable to National Standards. (UKAS Calibration Laboratory N° 0157). The above results are obtained on the date of calibration. The percentage error quoted refers to the measured values only, with no account being taken of the instruments ability to maintain its calibration.

Velocity Range

Is calibrated for the ellipsoidal nose (NPL Type) Pitot Static Tubes used at air density 1.20kg/m³. Air stream temperature set at 16°C and barometric pressure set at 1000 mbar on the instrument.

Calibrated by Hussein Khimji:

Section 1.0 – Scope of Works

Annual Inspection of Critical Ventilation Systems

To carry out a compliance and performance inspection of all critical path ventilation systems in accordance with - Heating and Ventilation Systems - SHTM – Scottish Health Technical Memorandum 03-01: Specialised Ventilation for Healthcare Premises.

(Interim Version – Additional guidance related to COVID 19 to be added in an update in 2022)

Part B: The management, operating, maintenance and routine testing of existing healthcare ventilation systems.

The verification of the rooms was carried out to record an annual verification record for these rooms. This work followed post fitting of recirculation fans (Camfil Camcleaner 400 concealed fan units) located within the ceiling of the toilet of bedrooms in Adults – Ward 4C. The Camcleaner consists of a pre-filter (bag) and a secondary HEPA filter. See report details of fan settings, air volumes, room pressures and noise levels achieved while maintaining SHTM03-01 compliance.

Section 2.0 – Definition of Terms

Definition of terms used on survey form Assessment of compliance with Health Building Note 10-01 and Scottish Health Technical Memorandum 03-01 (all questions relevant to the type of theatre)

Poor

Air volumes and hence air-change rate is less than 80% of the design; room pressure differentials do not ensure a flow from clean to less clean areas; supply or extract air diffusers are not clean; pressure stabilisers not clean and/or not operating correctly; significant faults or failures of indicators on surgeon's panel; visible faults in the fabric of the suite; doors unable to close completely; general air of neglect.

Action: Urgent management action required.

Average

Air volumes and room pressure differentials approximate to the original design values; supply air diffusers clean but extracts visibly fouled; most pressure stabilisers clean and operating correctly; some of the indicators on the surgeon's panel not working; minor faults in the fabric and décor of the suite.

Action: Maintenance action required.

Good

Better than average.

Action: None.

Maintenance quality (all questions relevant to the type of theatre)

Poor

More than three answers are negative.

Action: Management action required by estates/facilities department.

Average

No more than three answers are negative

Action: Maintenance action required.

Good

No answers are negative.

Action: None.

Section 3.0 – Executive Summary & Observations

The evaluation of Adults – Ward 4C on level 4.

- To make sure the noise levels in the bedroom and en suite were compliant with SHTM03-01 which are bedroom 35dB(A) & en-suite 45dB(A)
- Noise levels and air volumes were measured to the various fan power levels on the recirculation unit in the en-suite (speed control setting level 1-6) Speed controller at setting 3 when all compliant and final values recorded within this report.

Observations

- All fabric issues have been reported to John Hetherton & Connor Stepney via email.
- Scrubber fan filter both F7 & H13 were changed prior to room verification for each room.
- Each room has their own separate condition which would refer to the chart below.

Values noted in colour relate to the table below		
Poor	Average	Good
Ventilation system should achieve not less than 80% of the design air change rate in accordance to the SHTM.	Air volumes and room pressure differentials approximate to the original design values.	Better than average.
Comments: Reference section 2.0 for more information.

CERTIFICATE OF CALIBRATION

Certificate number :	44956-1-3	Page No:	1 of 1
Customer :	CORRECT AIR SOLUTIONS	Date of calibration:	06 July 2022

Instrument :	Description: DIGITAL MANOMETER Manufacturer: DP MEASUREMENT BUCKINGHAM Type: RS232/TT570 Serial Number: DCL5342/8651	Job number: 44956 1/3 Previous calibration: N/A Accuracy of U.U.T: +/- 0.2 % of Indication +/- LSD Condition recieved: Satisfactory
--------------	---	---

Lab Conditions at time of calibration:	Temperature: 20.0 +/- 1.0 °C Supply Voltage: 230 +/- 12 Volts	Humidity: 50 % +/- 20 % Supply Frequency: 50 Hz +/- 1 Hz
--	--	---

Comments: The unit was allowed to stabilize for a period of 24 hours prior to calibration
 The unit was mounted in a horizontal position,
 The pressure medium was Dry Air,
 The unit was zeroed prior to calibration

The above instrument was calibrated using:

Plant No. G19 S/No. 221/96-5	UKAS Lab No. 0822	Certificate No. 94071
Plant No. G23 S/No. 85772	UKAS Lab No. 0690	Certificate No. 18204

Uncertainty of measurement & capabilities: +/- 0.02%

Calibration Information: This instrument was calibrated against laboratory standards whose values are traceable to National Standards.
 The uncertainty limits quoted refer to the measured values only, with no account being taken of the instruments ability to maintain its calibration
 The Calibration was carried out in accordance with BS EN ISO 17025 : 2017

Calibration readings:

Range (kPa)	Ind. on U.U.T. (kPa)	App. Std. (kPa)	% Deviation
7	0.00	0.000	0.0000
	0.50	0.490	2.0000
	1.00	0.990	1.0000
	2.00	2.005	-0.2500
	3.00	3.003	-0.1000
	4.00	3.998	0.0500

Risk Assessment Form – Airborne Pathogens

Activity being assessed:		Hazards identified: ✓					
The risk associated with exposure to airborne pathogens from the ventilation system, for immune compromised patients		Violence and aggression		Blood and body fluids		Radiation	
		Lone working		Machinery/equipment		Fire / Sources of ignition	
		Sharps		Hazardous substances		Ergonomic	
		Slips, trips, falls		Electricity		Work methodology	
		Manual Handling		Weather		Environment	X
Department:	Haemato- Oncology	Additional information: Ward 4C at the Queen Elizabeth University Hospital is a 10 single room unit caring for Haematooncology patients. A number of disease types are managed here but those most at risk of airborne fungal infections are patients with acute myeloid and lymphoblastic leukaemias. These patients typically endure long periods of neutropenia following intensive chemotherapy. Many of these patients are given anti-fungal prophylaxis medication which is highly effective. The other groups of patients treated for lymphoma, chronic leukaemias myeloma and autologous stem cell transplant are at low risk for fungal infection. Patients managed with allogeneic stem cell transplantation are not treated on ward 4C but are treated in the adjacent transplant unit, ward 4B. Patients undergoing treatment for acute leukaemia are normally confined to their room and only leave for essential imaging or diagnostic procedures. These patients are also high risk for bacterial infection, the source of which is normally the patient's own skin, lung and gut commensal flora during periods of severe neutropenia. We regularly monitor these patients for features suggestive of fungal infection; namely fevers refractory to broad spectrum antibiotics, new pulmonary infiltrates, skin lesions, serological testing and relevant cultures from blood, indwelling lines, sputum, tissue or body fluids. We have not noted any change in the background low incidence of these infections compared to those identified historically					
Location:	Ward 4C QEUH						
Person(s) exposed:		Patients with weakened immune systems					
Control measures currently in place:						Specific risk assessments or guidance to be referred to:	
1. NICE guidelines (2016) recommending the use of single rooms for accommodating high-risk patients. All accommodation in Ward 4C is in single rooms. https://www.nice.org.uk/guidance/ng47/resources/haematological-cancers-improving-outcomes-pdf-1837457868229						 haematological-cancers-improving-outcom	

Risk Assessment Form – Airborne Pathogens

2. **antimicrobial prophylaxis** medicines : The use of **antimicrobial prophylaxis** medicines are strongly recommended in patients being treated for acute leukaemia. Several classes of drugs are used for prophylaxis but the azoles, particularly posaconazole, are the most commonly used. Posaconazole has been shown in multi-centre, randomised controlled trials to be highly effective, in one trial published in the NEJM showing a reduction in overall mortality in addition to fungal related mortality. Furthermore, there is prospective, observational, single centre, real-life data showing significant clinical benefit. In addition there is a good understanding of how posaconazole works at the cellular level that explains its efficacy as a prophylactic agent. All international guidelines including IDSA and ESCMID recommend anti-fungal prophylaxis in high-risk patients.

3. Regular routine surveillance for possible fungal infection as noted above.

4. Management of patients in single rooms with movement outside this environment only for essential imaging or diagnostic/therapeutic procedures. Limited access by visitors.

5. Adults Ward 4C is located on the 4th floor of the Queen Elizabeth University Hospital and is supplied by 3 Air Handling Units located on level 12 plant room 124, these AH-units also serve adjacent ward levels 5, 6 & 7 for the C core and have thermal wheel recovery incorporated within them at source. The original filtration and pressure set up from building hand over for ward 4C was as follows :

General ward - G4 rated primary filtration and F7 Secondary filtration at source with an ambient (0pa) pressure cascade from room to corridor.

As an additional risk reducing measure within ward 4C, installation of recirculation air scrubber fans (Camfil Camcleaner 400 concealed fan units) located within the ceiling of each toilet bedroom on ward 4C was carried out and then each space validated to quantify the improvements achieved. The Cam cleaner consists of a pre-filter (bag) and a secondary HEPA filter. See report details of fan settings, air volumes, room pressures and noise levels achieved while maintaining SHTM03-01 compliance.

Subsequent improvement modifications include :

1. Oct/Nov 2018 plant re calibration and ventilation system re balance to change ward 4C Room Differential pressures to corridor to be nominally positive (+ve)
2. Jan 2019 Installation of F9 secondary filtration to improve the source air quality delivered to these departments.
3. Jan 2019 Deployment of mobile city M HEPPA air scrubbers to assist in reducing the existing particulate within the Air.
4. January 2020 CVG (Ceiling Ventilation Grilles x10) removed and replaced with a standard ceiling tile to reduce the risk of particulate moving from the corridor ceiling void into the corridor transfer area and rooms.

Risk Assessment Form – Airborne Pathogens

5. 4C, installation of recirculation air scrubber fans and particulate counts carried out in October 2020.

December 2020, Post Survey meaning verification completed on conclusion of works it is confirmed that the current example performance within ward 4C is reflective :

From :

- 1) Room ACRs = 3AC/HR
- 2) EN-suite ACRs = 6AC/HR
- 3) Room Differential pressures to corridor to be nominally positive (+ve)
- 4) EN-suite toilet to be -ve to the room.

Department:	Haemato- Oncology	Additional information: Ward 4C at the Queen Elizabeth University Hospital is a 10 single room unit caring for Haematooncology patients. A number of disease types are managed here but those most at risk of airborne fungal infections are patients with acute myeloid and lymphoblastic leukaemias. These patients typically endure long periods of neutropenia following intensive chemotherapy. Many of these patients are given anti-fungal prophylaxis medication which is highly effective. The other groups of patients treated for lymphoma, chronic leukaemias myeloma and autologous stem cell transplant are at low risk for fungal infection. Patients managed with allogeneic stem cell transplantation are not treated on ward 4C but are treated in the adjacent transplant unit, ward 4B. Patients undergoing treatment for acute leukaemia are normally confined to their room and only leave for essential imaging or diagnostic procedures. These patients are also high risk for bacterial infection, the source of which is normally the patient's own skin, lung and gut commensal flora during periods of severe neutropenia. We regularly monitor these patients for features suggestive of fungal infection; namely fevers refractory to broad spectrum antibiotics, new pulmonary infiltrates, skin lesions, serological testing and relevant cultures from blood, indwelling lines, sputum, tissue or body fluids. We have not noted any change in the background low incidence of these infections compared to those identified historically					
Location:	Ward 4C QEUH						
Person(s) exposed:		Patients with weakened immune systems					
Control measures currently in place:						Specific risk assessments or guidance to be referred to:	
1. NICE guidelines (2016) recommending the use of single rooms for accommodating high-risk patients. All accommodation in Ward 4C is in single rooms. 2. Anti-fungal prophylactic medicines : The use of anti-fungal prophylaxis is strongly recommended in patients being treated for acute leukaemia. Several classes of drugs are used for prophylaxis but the azoles, particularly posaconazole,						NICE Guidelines 2016 IDSA ESCMID Infection Rates reports	

Risk Assessment Form – Airborne Pathogens

are the most commonly used. Posaconazole has been shown in multi-centre, randomised controlled trials to be highly effective, in one trial published in the NEJM showing a reduction in overall mortality in addition to fungal related mortality. Furthermore, there is prospective, observational, single centre, real-life data showing significant clinical benefit. In addition there is a good understanding of how posaconazole works at the cellular level that explains its efficacy as a prophylactic agent. All international guidelines including IDSA and ESCMID recommend anti-fungal prophylaxis in high-risk patients.

3. Regular routine surveillance for possible fungal infection as noted above.

4. Management of patients in single rooms with movement outside this environment only for essential imaging or diagnostic/therapeutic procedures. Limited access by visitors.

5. We propose regular air sampling monitoring for fungal species and other airborne pathogens for all single rooms in ward 4C.

6. Adults Ward 4C is located on the 4th floor of the Queen Elizabeth University Hospital and is supplied by 3 Air Handling Units located on level 12 plant room 124, these AH-units also serve adjacent ward levels 5,6 &7 for the C core and have thermal wheel recovery incorporated within them at source. The original filtration and pressure set up from building hand over for ward 4C was as follows :

General ward - G4 rated primary filtration and F7 Secondary filtration at source with an ambient (0pa) pressure cascade from room to corridor and a non-official derogated ACH Rate from SHTM03-01.

Subsequent improvement modifications include :

1. Oct/Nov 2018 plant re calibration and ventilation system re balance to change ward 4C Room Differential pressures to corridor to be nominally positive (+ve)
2. Jan 2019 Installation of F9 secondary filtration to improve the source air quality delivered to these departments.
3. Deployment of mobile city M HEPPA air scrubbers to assist in reducing the existing particulate within the Air.
4. CVG (Ceiling Ventilation Grilles x10) removed and replaced with a standard ceiling tile to reduce the risk of particulate moving from the corridor ceiling void into the corridor transfer area and rooms.

Now post survey it is confirmed that the current performance within ward 4C is reflective of :

Risk Assessment Form – Airborne Pathogens

- 1) Room ACRs = 3AC/HR
- 2) EN-suite ACRs = 6AC/HR
- 3) Room Differential pressures to corridor to be nominally positive (+ve)
- 4) EN-suite toilet to be -ve to the room.

Risk Assessment Form – Airborne Pathogens

Evaluation of Risk:						Additional Control Measures Required:																																										
<table border="1"> <thead> <tr> <th>Likelihood</th> <th colspan="5">Severity</th> </tr> <tr> <th></th> <th>Negligible 1</th> <th>Minor 2</th> <th>Moderate 3</th> <th>Major 4</th> <th>Extreme 5</th> </tr> </thead> <tbody> <tr> <td>Almost Certain 5</td> <td>Medium</td> <td>High</td> <td>High</td> <td>V High</td> <td>V High</td> </tr> <tr> <td>Likely 4</td> <td>Medium</td> <td>Medium</td> <td>High</td> <td>High</td> <td>V High</td> </tr> <tr> <td>Possible 3</td> <td>Low</td> <td>Medium</td> <td>Medium</td> <td>High</td> <td>High</td> </tr> <tr> <td>Unlikely 2</td> <td>Low</td> <td>Medium</td> <td>Medium</td> <td>Medium</td> <td>High</td> </tr> <tr> <td>Rare 1</td> <td>Low</td> <td>Low</td> <td>Low</td> <td>Medium</td> <td>Medium</td> </tr> </tbody> </table>						Likelihood	Severity						Negligible 1	Minor 2	Moderate 3	Major 4	Extreme 5	Almost Certain 5	Medium	High	High	V High	V High	Likely 4	Medium	Medium	High	High	V High	Possible 3	Low	Medium	Medium	High	High	Unlikely 2	Low	Medium	Medium	Medium	High	Rare 1	Low	Low	Low	Medium	Medium	Beyond those listed above no further control measures are required. As the risk score is medium, Clinical and Estates management will progress with developing a scheme of works to further enhance the environment to reduce the risk level further.
Likelihood	Severity																																															
	Negligible 1	Minor 2	Moderate 3	Major 4	Extreme 5																																											
Almost Certain 5	Medium	High	High	V High	V High																																											
Likely 4	Medium	Medium	High	High	V High																																											
Possible 3	Low	Medium	Medium	High	High																																											
Unlikely 2	Low	Medium	Medium	Medium	High																																											
Rare 1	Low	Low	Low	Medium	Medium																																											
Likelihood Rare - Can't believe this event would happen – will only happen in exceptional circumstances. Unlikely - Not expected to happen, but definite potential exists Possible - May occur occasionally, has happened before on occasions Likely - Strong possibility that this could occur Almost Certain - This is expected to occur frequently / in most circumstances		Severity Negligible – minor injury first aid not required Minor – minor injury or illness first aid required Moderate – agency reportable, significant injury/illness medical treatment or counselling required Major – major injury or long term incapacity/disability Extreme – death or permanent incapacity																																														
Likelihood x Severity = Risk level 3 x 2 = 6 (medium)

Executive Summary

Cundall were appointed by Graham Construction Ltd to assess whether the existing Air Handling Units (AHUs) AHU 04 & AHU 05 located within plant room 124 has any additional capacity to allow the volume of air delivered to the single patient rooms within wards 4C, 5C, 6C and 7C at Queen Elizabeth University Hospital (QEUH) located at 1345 Govan Rd, Glasgow G51 4TF to be increased to allow an air change rate to 6 air changes per hour (ACH) or higher.

This feasibility report will review the existing plant and highlight the associated works required to existing services as well as listing any additional equipment needed to achieve increased ventilation rates.

At the time of writing, we approached Barkell, the manufacturer of the AHUs installed at the QEUH to seek assistance with the three scenarios posed by the end client, NHSGG&C. Barkell originally engaged with us to review modifications and alterations, However, they broke off communications due to ongoing Legal Proceedings between them (Barkell) and their Client, Mercury Engineering.

1.0

Introduction

1.0 Introduction

1.1 Purpose of analysis

The purpose of this report is to determine the viability for increasing the ventilation rates within the single bedrooms on wards 4C, 5C, 6C and 7C to 6 ach. These wards are located on levels 4 to 7.

This report will only address the impact of increasing the ventilation rates to the single bedroom within these wards. The ventilation rates for all other rooms served by the same system will not be considered and will remain the same.

Ward 4C has 25 No. single bedrooms and floors wards 5C, 6C and 7C have 28 No. single bedrooms on each.

The analysis will also assess the impact this will have on the existing installation and recommended modifications required to facilitate the increase in ventilation rates.

This report will investigate each of the following scenarios as posed by NHSGG&C:

- Utilising existing ductwork, fans and AHU carcasses, can we increase air volume supply to all floors to achieve the required 6 ach.
- Utilising existing ductwork, AHU carcasses and altering the pulleys on the existing fans, can we increase air volume supply to all floors to achieve the required 6 ach.
- Utilising existing ductwork, AHU carcasses and changing the existing fan arrangement to EC fans (perhaps a fan wall), can we increase air volume supply to all floors to achieve the required 6 ach.
- In all of the scenarios above, can we increase the air volume supply to just one floor to 6 ach.

2.0

System description

2.0 System description

2.1 System description

Wards 4C, 5C, 6C and 7C ventilation is currently served by AHU 04 & AHU 05 located on level 12 plantroom 124. The ventilation ducts from the AHUs drop down the mechanical riser to serve floors 4 to 7. Ducts then distribute from the riser through the ceiling voids to serve the wards.

Conditioned air is then supplied to the single bedrooms via a Swegon Parasol ceiling mounted heating / cooling terminal unit. This unit tempers the supply air via heating and cooling coils to achieve the rooms winter and summer design conditions.

Air is extracted from the en-suite, through a door mounted grill and then via a valve type terminal, before being ducted back through the ceiling voids to the mechanical services riser before returning to AHUs 04 & 05 located on level 12.

AHUs 04 & 05 only serve wards 4C, 5C, 6C & 7C with AHU 04 serving the lower portion of the wards and AHU 05 serving the upper portion.

It was noticed that the extract system serving the single bedrooms on the wards also serves the toilets within the general areas.

Extract air volumes are higher than supply volumes meaning that the single bed wards are under negative pressure in relation to corridors.

3.0

Assessment

3.0 Assessment

3.1 Existing room air change rates

The following supply and extract air volumes were calculated based on H&V commissioning data sheets.

3.1.1 Level 4 - Ward 4C

Sub total								561	640	

Note: the maximum fresh air supply to the existing Swegon Parasol ceiling terminals is limited to 40 l/s.

The tables above illustrate the existing ventilation air change rate for the single bedrooms to be between 2.7 to 3.2 ach.

3.2 Proposed air volumes

The following supply and extract air volumes were calculated to achieve the required 6 ach. Note, we have assumed balanced air volumes for the purposes of the report. If the single bed wards are to be under negative pressure this will increase the extract volumes.

3.2.1 Level 4 - Ward 4C

4.0

Impact on the existing installation

4.0 Impact on the existing installation

4.1 Air Handling Units

From the information provided, the manufacturers technical detail for the existing AHUs are as follow:

AHU ref:	AHU 04	AHU ref:	AHU 05
Manufacturer:	BARKELL Ltd	Manufacturer:	BARKELL Ltd
Fan model:	TZAF400FFR	Fan model:	TZAF400FFR
Design supply air flow (100%):	2.56 m ³ /s	Design supply air flow (100%):	2.36 m ³ /s
Design supply air flow (125%):	3.2 m ³ /s	Design supply air flow (125%):	2.95 m ³ /s
Total static pressure:	928 Pa	Total static pressure:	852 Pa
Fan model:	TZAF450FFR	Fan model:	TZAF500FFR
Design extract air flow (100%):	2.61 m ³ /s	Design extract air flow (100%):	3.06 m ³ /s
Design extract air flow (125%):	3.26 m ³ /s	Design extract air flow (125%):	3.83 m ³ /s
Total static pressure:	657 Pa	Total static pressure:	676 Pa

Table 4.1 – Existing AHUs information

Note:

- The technical information provided states that the existing AHUs are designed to operate at 125% duty.
- AHUs are manufactured to DW143 Class B leakage standard.

The H&V commissioning sheets identifies the following:

AHU ref:	Supply		Extract	
	Design (m ³ /s)	Actual (m ³ /s)	Design (m ³ /s)	Actual (m ³ /s)
AHU 04	2.56	2.788	2.608	2.75
AHU 05	2.36	2.502	3.064	3.193

Table 4.2 – AHU 04 Existing, required and shortfall supply and extract rates serving single bedrooms per floor

The table below shows the required AHU duties in order to achieve the required 6 ach to all the single bedrooms within all 4 floors:

AHU 04

Floor	Existing		Required		Shortfall	
	Supply	Extract	Supply	Extract	Supply	Extract
	l/s	l/s	l/s	l/s	l/s	l/s
4th	483	545	914	914	431	370
5th	565	632	1066	1066	501	435
6th	569	649	1063	1063	494	414
7th	562	648	1065	1065	503	417
Total	2180	2473	4109	4109	1929	1636

Table 4.3 – AHU 04 Existing, required and shortfall supply and extract rates serving single bedrooms per floor

AHU 05

Floor	Existing		Required		Shortfall	
	Supply	Extract	Supply	Extract	Supply	Extract
	l/s	l/s	l/s	l/s	l/s	l/s
4th	529	591	975	975	447	384
5th	561	640	1062	1062	501	422
6th	569	649	1066	1066	497	417
7th	565	652	1061	1061	496	409
Total	2223	2531	4165	4165	1941	1634

Table 4.4 – AHU 05 Existing, required and shortfall supply and extract rates serving single bedrooms per floor

Note: The total volumes shown above are the sum of the ventilation rates required for the single rooms only and do not include other rooms served by the same system e.g. Day Trolleys rooms, non ensuite WCs etc.

The AHU manufacturer confirmed that the existing AHUs cannot provide the required air volumes to achieve single bedroom 6 ach. The limiting factors are the existing fans, motors and cooling and heating coils. The manufacturer confirmed that by replacing the existing belt driven fans with a more efficient solution such as an EC plenum direct drive fan array (fan motors will be located in the airstream) and replacing the existing cooling and heating coil section on the supply AHU with a taller section and larger coils section, the existing AHU duties can be increased.

We were awaiting confirmation from the AHU manufacturer on what additional air volume these changes will achieve. This would have determined the number of floors this option could serve.

4.1.1 Supply and extract duct

4.1.1.1 Riser:

The following table illustrates the impact of increasing the ventilation rates on the riser ductwork:

AHU	System	Floor	Duct size	Existing		Proposed	
				Flowrate	Velocity	Flowrate	Velocity
			(mm x mm)	(m ³ /s)	(m/s)	(m ³ /s)	(m/s)
AHU 04	Extract	4	550 x 300	0.660	4.0	1.065	6.5
AHU 04	Extract	5	600 x 500	1.317	4.4	2.197	7.3
AHU 04	Extract	6	750 x 600	1.989	4.4	3.324	7.4
AHU 04	Extract	7	1000 x 600	2.660	4.4	4.453	7.4

Table 4.1.1.1 – Air velocities within the existing riser

CIBSE guide B table 3.4 recommends the maximum air velocity within risers for rectangular duct in critical areas should be limited to 5 m/s and 7.5m/s in normal areas.

Table 1.5.2.1 shows by increasing the air volumes within the existing riser ducts to the required volumes to achieve the 6 ach would increase the air velocity within the ducts to above the CIBSE guidance.

Due to spatial constraints within the riser, there is minimal scope to increase the size of the ducts within the riser particularly from levels 12 through to 7. If the trust deems the increase in air velocities within the riser ducts acceptable, the existing riser ducts may be retained. The riser ducts may be acoustically treated if required.

Table 4.1.1.8 – Air velocities within the existing distribution ducts

CIBSE guide B table 3.4 recommends the maximum duct air velocity within ceilings for rectangular duct in critical areas should be limited to 3 m/s and 5 m/s in normal areas. Furthermore, for circular ducts 5 m/s in critical areas and 7 m/s in normal areas.

Table 1.5.2.1 shows by increasing the air volumes within the existing riser ducts to the required volumes to achieve the 6 ach would increase the air velocity within the ducts to above the CIBSE guidance.

4.1.1.3 Supply terminals

Fresh air is currently delivered to the single bedrooms via a flush ceiling mounted Swegon – Parasol unit, these units provide fresh air as well as heating and cooling. The H&V commissioning sheets shows the air supplied to each unit is around 40 l/s. The literature available online suggests the maximum fresh air permitted through these units is 49 l/s.

This small increase will not achieve the required 6 ach. Furthermore, increasing the air volume through these units will have a significant impact on the noise generated by the unit as well as a significant increase in the system pressure.

4.1.1.4 Extract Terminals

Air is extracted from the adjacent ensuite through door mounted transfer grilles and then via a ceiling mounted circular extract valve terminals. We do not anticipate that changing the air volumes will have a significant impact on the noise levels generated by these terminals.

However, it may be necessary to increase the size of the door mounted transfer grilles, although this will need to be assessed when the exact transfer grille type and size are known.

5.0

Scenarios

5.0 Scenarios

5.1 Review of scenarios

From the desktop study, the AHUs were designed to achieve the duties set out by the original designers. Even though it may be possible to replace specific elements from within the AHU to increase its performance, this will have further implication on the overall AHU. The impact of any changes will affect the following aspects:

1. AHU Specific Fan Power (SFP); This measures the AHU's fan energy efficiency and is a building regulation requirement that should be met.
2. Air leakage due to over pressurisation of the unit and distribution system; The AHU carcasses, intake, discharge and distribution ducts are sizes in line with the parameters set out by the designers. By retaining the existing system and increasing the air volume, the system pressure will increase, which may impact the system performance and potentially result in not achieving the required air volumes.
3. Performance of the heating and cooling coils; The coils are sized to achieve a specific thermal transfer at a specific air velocity, by increasing the air volume withing the existing AHU, the air velocity through the coils will increase resulting in insufficient thermal transfer. This will have a big impact on the entire systems especially on the Swegon ceiling mounted units resulting in condensation. This will also increase the risk of moisture carry over within the air stream from the cooling coils due to the higher velocity.
4. Noise levels; increasing air velocity through the ducts will result in higher noise levels through out the system. This will impact the room current noise levels.
5. Intake and exhaust louver sizing; The existing louvers are sized to cope with the current air volumes, increasing the air volume will result in higher static pressure and noise levels
6. System static pressure, increasing air volume through the distribution system will result in higher system static pressure. This will impact the fan performance and system air leakage.
7. Shorter economic life expectancy for the unit, by essentially over running the AHU, the expected economic life expectancy will be reduced due to additional ware and tear, this will also result in greater maintenance requirement and higher energy/running costs.

Impact on the existing supply and extract ducts, The existing distribution system is sized on the current ventilation rates, the existing system is inadequately sized to facilitate the increased air volume, it should be noted that as the rooms are currently designed to be negatively pressurised, the existing extract ducts are generally larger that the supply duct resulting in lower air velocities.

Increasing the air volume through the distribution system will increase the air velocity within the ducts above the industry guidance stated within CIBSE Guide B. This will result in higher noise levels, the supply and extract terminals and increased air leakage. It should also be noted that the existing Swegon ceiling mounted induction units within the bedroom as limited to 49 l/s, the required air volume needed to achieve the 6 ach is more that the unit allowance making it inadequate for this purpose.

Duct location	Duct type	Maximum air velocity / m·s ⁻¹ for stated room type		
		Critical	Normal	Non-critical
Riser or above plasterboard ceiling	Rectangular	5	7.5	10
	Circular	7	10	15
Above suspended ceiling	Rectangular	3	5	6
	Circular	5	7	10

Scenario 1:

Utilising existing ductwork, fans and AHU carcasses, can we increase air volume supply to all floors to achieve the required 6 ach.

Figure 5.1 shows that the fans have been selected to operate in the lower range of the fan curve, this does give some scope to increase the air volume within the system. However, even though the fan may provide the required volumes, the noise level increase resulting from the increase in duty will require additional treatment consisting of acoustically lining the existing ducts and replacing the existing duct mounted attenuators located within the plantroom.

Figure 5.1 – AHU 04 supply existing and increased air volume plotted on Comefri TZAF 400 FF fan curve.

Increasing the AHU's duty will impact the energy consumption, Fan SFP and carbon rating of the unit.

The fact that the fans may achieve the volumes is not the only limiting factor. From the study, it was established that coils within the AHU are not capable of facilitating the required air volume needed to achieve the 6 ach for all floors. Furthermore, the existing distribution ductwork within the risers and ceiling voids are not sized for the required air volume. This will result in excessive air velocities within the ductwork. The impact of the increased velocities within the riser may be acceptable subject to confirmation from the trust. However, The increased velocities within the distribution ducts will need to be addressed. This will require new dew ductwork from the riser to the rooms running parallel to the existing distribution system or replacing the existing distribution system with a new distribution system sized to facilitate the required air volumes.

We were advised by AHU manufacturer that the limiting factors on these AHUs are the sizes of the coils as well as the physical sizes on the AHU. Increasing the air flowrate through the unit by changing the fans, pullies or any other method would have a detrimental effect on the efficiencies of the coils resulting in incomplete thermal transfer between the coils and the air, increased risk of moisture droplets carried over within the air stream due to increased velocities, this is particularly critical within this system due to the fact this will increase the risk of condensation within the rooms.

New supplementary supply diffusers will need to be installed in all single bedroom to provide the additional fresh air as the current fresh air rates supplied to the rooms via the Swegon Parasol ceiling terminals can't be increased.

New door transfer grills will need to be installed on the doors between the room and en-suites.

Also, Confirmation is required from the AHU manufacturer if the existing components within the AHU such as bearings will need to be upgraded to facilitate the increase in air volume.

Taking all of the above into consideration, we consider this scenario to be not feasible.

Scenario 2:

Utilising existing ductwork, AHU carcasses and altering the pulleys on the existing fans, can we increase air volume supply to all floors to achieve the required 6 ach.

This scenario is also not feasible for the same reason stated in Scenario 1.

Scenario 3:

Utilising existing ductwork, AHU carcasses and changing the existing fan arrangement to EC fans (perhaps a fan wall), can we increase air volume supply to all floors to achieve the required 6 ach.

Even though replacing the fans will result in a higher air volume, the limiting factor within the AHU are the size of the existing units and coils.

By replacing the existing belt driven fans with a more efficient solution such as an EC plenum direct drive fan array (fan motors will be located in the airstream) and replacing the existing cooling and heating coil section on the supply AHU with a taller section and larger coils section. This will allow the existing fresh air supply volume to be increased. However, It is very unlikely that the full required air volume needed to achieve the 6 ach can be achieved. We are awaiting confirmation from the AHU manufacturer on what additional air volume these changes will have on the AHU supply. This will determine the number of floors this option can serve.

It should be noted that even though the required air volumes may be achieved, the existing distribution ductwork within the risers and ceiling void are not adequately sized for the new air volumes. Below are possible options to overcome this issue:

Option 3.1: Retain the existing AHU and upgrade the existing fan, motor, cooling and heating coils, retain the existing ductwork within the plant room and riser (velocity between 6.5 & 8.5) as there is minimal scope to increase the duct size in the riser due to space constraints. Retain the existing distribution ductwork within the floors serving the Swegon Parasol ceiling terminals and install a new duct branch from the riser and run parallel to the existing duct to serve new supplementary diffusers within each single bedroom. The existing extract duct system will need to be recommissioned resulting in higher extract velocities. New door transfer grilles will need to be installed between the rooms and en-suite to ensure adequate return air path.

Option 3.2: Take a new branch from the existing supply air plenum leaving the supply AHU. Air within the new branch will need to be conditioned via cooling and heating coils within the plant room to ensure thermal comfort prior to dropping to below (riser location yet to be identified). Retain the existing distribution ductwork within the plantroom, riser and floors serving the Swegon Parasol ceiling terminals and install a new duct work from the new supply duct within the riser and run parallel to the existing duct to serve new supplementary diffusers within each single bedroom. New door transfer grilles will need to be installed between the rooms and en-suite to ensure adequate return air path.

Option 3.3: Strip out existing ventilation system including AHU 04 & 05, retain the existing ductwork within the riser (velocity between 6.5 & 8.5) as there is minimal scope to increase the duct size in the riser due to space constraints, strip out the distribution ductwork and Swegon Parasol ceiling terminals within all floors. Install a new AHU sized to deliver the required air volume in same locations of the existing AHUs. Install new ductwork within the plantroom, distribution ductwork within the floors and new diffusers and grills within the rooms/en-suits. The room heating and cooling will be provided via the ventilation system with a supply air temperature of 14°C for summer conditions and either radiant panels in the rooms or heater batteries on branches serving multiple rooms to condition the air for winter conditions.

New door transfer grilles will need to be installed between the rooms and en-suite to ensure adequate return air path.

All the above option assumes that there is sufficient space within the corridor ceiling void to allow the installation of a new supply duct to serve the new supplementary supply diffusers.

Scenario 4:

From the Variable Speed Drivers (VSD)s information below provided by the trust, there is some scope to increase the duty of AHU 05 by adjusting the VSD. However, the increase would be limited to about 20-25% at best which will cover a single floor. This is on the basis that the existing AHU is designed to run at 125% of the original design duty.

This is not the case for AHU 04 as the VSD is currently operating close to its upper limit.

From the information provided by the trust, the existing VSD serving these AHU as currently set to the following parameters:

AHU 04:

Supply fan VSD: 50 Hz

Extract fan VSD: 60 Hz

AHU 05:

Supply fan VSD: 47 Hz

Extract fan VSD: 37 Hz

It should be noted that further consideration would need to be given to the impact this will have on the existing units SFP and the face velocity at the cooling coils. Also, this will reduce the allowance made for operating the AHU with a dirty filter. This will require the filters to be replaced at a higher frequency to ensure that the required air volumes are achieved.

Adjusting the VSD will result in the following increase:

AHU ref:	Existing		Proposed	
	Supply	Extract	Supply	Extract
	(m ³ /s)	(m ³ /s)	(m ³ /s)	(m ³ /s)
AHU 05	2.502	3.193	3.128	3.99

Table 5.2 – Proposed AHU air volume increase

This can facilitate either of these two options:

Option 4.1: increase all single bedroom ventilation rate on a single floor served by AHU 05 to 6 ach and maintain 3 floors at their existing ventilation rates.

The existing ductwork within the plantroom, riser and distribution within all floors will be retained, however, a new supply distribution duct will need to be installed on the selected floor running parallel to the existing duct to serve new supplementary diffusers within the single bedrooms.

New door transfer grills will need to be installed on the doors between the room and en-suites.

The existing extract system will need to be recommissioned to facilitate the higher ventilation rates. This will result in higher duct velocities as shown in tables 4.1.1.6 to 4.1.1.8

Option 4.2: Increase all single bedroom ventilation rate within all 4 wards (4C, 5C, 6C and 7C) from between 2.7 and 3.2 ach to between 3.5 and 4.2 ach.

This option will increase the fresh air supply to the single bedrooms from about 40 l/s to 52 l/s. This increase will push the supply flowrate over the maximum amount of fresh air permitted through the existing Swegon Parasol ceiling terminals. Therefore, new supplementary diffusers will need to be installed in each single bedroom to supply the additional 12 l/s. These diffusers will be served by the existing duct serving the Swegon Parasol ceiling terminals.

New door transfer grills will need to be installed on the doors between the room and en-suites.

The existing extract system will need to be recommissioned to facilitate the higher ventilation rates. This will result in higher duct velocities.

We understand that the trust has been advised that the Chilled Water (CHW) pipework serving the existing Swegon Parasol ceiling terminals need to be replaced due to corrosion. Therefore, there will be a level of disruption from the plate heat exchanges and throughout the floors. This period could be utilised to carry out the changes to the existing ventilation system as required.

AHU 04 fan, motor and VSD will need to be upgraded to enable any increase in its existing duty. This upgrade would enable the implementation of option 4.1 and 4.2.

6.0

Summary of findings

6.0 Summary of findings

6.1 Summary of findings

The ventilation air change rates for the single bedrooms within wards 4C, 5C, 6C and 7C were found to be between 2.7 and 3.2 ach, this is lower than the SHTM 03-01 Table A1 – Design conditions for miscellaneous room recommendation of 6 ach.

The single bedrooms and associated en-suite are commissioned to operate under a negative pressure in relation to the adjacent circulation space.

The supply and extract distribution ducts within the risers and ceiling voids are inadequately sized to facilitate the required air volumes needed to achieve the single bedrooms 6 ach.

The maximum fresh air permitted through the Swegon Parasol ceiling terminals is significantly lower than what is required to achieve the required 6 ach within the single bedrooms.

We do not anticipate that changing the air volumes will have a significant impact on the noise levels generated by the extract valve terminals.

The existing AHU fans, motors, cooling and heating coils are deemed inadequate to facilitate the required ventilation rate increase. The sizes of LTHW and chilled water pipework serving the exist AHUs will need to be reviewed.

The optimum solution would be the complete replacement of the existing AHU as this will ensure the required duty is achieved as well as a significant annual energy savings from the increased heat recovery efficiency and EC fan technology in a state-of-the-art AHU.

A further advantage of replacing the existing AHU is that if adequately sized, the single bedrooms heating and cooling requirement can be provided via the ventilation system. The existing Swegon Parasol ceiling terminals will no longer be required.

QUEEN ELIZABETH UNIVERSITY HOSPITAL – HAEMATO-ONCOLOGY WARD, LEVEL 4

BRIEFING NOTE ON DESIGN OF UNIT

1.0 BOARD'S REQUIREMENTS

The requirements are set out in the following documents;

- Clinical output specification for Haemato-oncology
- SHPN 054 Facilities for Cancer Centres
- SHTM 03-01 Ventilation for Healthcare Premises

In summary, the above documents collectively set the following design parameters; a sealed room, HEPA filtration, single rooms to have positive pressure from rest of hospital and an enhanced air change rate.

Compensation event No.051 was issued on 2nd October 2013 and instructed that an additional number of rooms, that were then in the Renal Ward, should be built to the same specification as those in the Haemato-oncology Ward. There was no detail within the change control form, from the service, to suggest that these rooms should be anything more than HEPA filtered and built to same standard as the 10 planned Haemato-oncology rooms.

2.0 DESIGN DEVELOPMENT

Designs for the department were developed based on a single room with en-suite, the model used elsewhere in the hospital, in other words individual lobbied rooms were not a user requirement. Designs were developed during the Phase 2 design development process in 2010 by the NHS user team, NHS Project Team, Brookfield Multiplex(BM) and their design team. It is not clear as yet where design assumptions were made that did not include all elements of the Board's specification noted above; and this is the subject of a review being undertaken by the BM design team.

What is clear, a design was concluded for the ward that did not meet all the requirements/recommendations and this progressed through to construction on site.

3.0 WHAT HAS BEEN BUILT

The rooms as constructed meet a range of the Board's design requirements, sealed external window, no chilled beam, HEPA filtration, positive pressured room, air system supplying 6 air changes per hour. The key design issue that appears to be affecting the operation of the air system and the high particle count is that the ceiling is not sealed. This is probably not allowing the air handling plant to reach its desired room pressure due to leakage into the ceiling void, and particles may transfer from this void into the room via loose fitting tiles or through the doorway when open due to drop in room pressure.

4.0 COMMISSIONING

The ventilation system serving the ward has been commissioned in accordance with CIBSE Commissioning Code A and the design air flow rate (based on 6ac/h). Thereafter sample room pressures were checked to confirm a positive differential pressure between the bedrooms and the corridor (generally 3-4Pa). The differential pressure was also checked between the ward exits and the cores / corridors again to ensure positive pressure (generally 1.5-2.5Pa). HEPA Filters were installed within all the bedrooms and visually checked to ensure seals were sound.

The Supervisor's (Capita) scope of work does not include design, build, commissioning and validation. The overall role of the Supervisor is to witness or carry out tests and inspections. The Supervisor also notifies Defects but may not accept a defect. The Supervisor is required to ensure that the works are provided to the standard and performance required in the works information. The works information for this ward was the Construction Issue drawings and specification which, as we now know, had shortcomings.

5.0 OPTIONS FOR SOLUTION

5.1 Testing Existing Installation

The Brookfield Multiplex team will undertake testing over the next 7 days, and will carry out a validation test (Air flow and static differential pressure test) on the rooms as they currently sit.

They intend to test 3 of the rooms with regards what can be achieved by sealing the rooms.

- Room 1 - seal the perimeter,
- Room 2 - seal the perimeter and the tiles
- Room 3 - we have ordered an alternative ceiling grid system which will confirm delivery of shortly. This is a manufactured self-sealing system (commonly found in theaters and CAT III rooms)
- All Rooms - adjust AHU performance to ensure optimal output
- All Rooms - install IP44 diffusers to light fittings

A further test will be taken at this point to understand the benefits of carrying this out (air flow and static differential pressure test).

We would require the Board to carry out a deep/clinical clean of the three rooms to allow a particle count to be taken at this time and we would like this to be undertaken by the Board's Infection Control team.

The purpose of the feasibility study is to establish the optimal position we can achieve with the currently installed services. Should test results meet the Board's requirements this would lead to minimal disruption and necessity of works (reducing the time the ward is rendered unavailable). At this time, should we achieve acceptable outputs we would present a formal submission to the NHS for agreement/approval, and this will need to include all design criteria on which the finished works would be measured by. Should all parties agree this will close the issue.

5.2 Alter Existing Installation

In carrying out the testing regime proposed above we will have a joint understanding of the capacity currently available with the installed system. The tests we are proposing are carried out (both by BMCE and the NHS) will provide information that will allow consideration to be given to the actual clinical performance of the rooms tested. Should an acceptable performance level be achieved we would carry out the following:

- Empty the rooms of all Board equipment to an agreed storage area.
- Remove the existing ceilings and services.
- Clean ductwork

- Install the new style sealed ceiling and replace the services as required dependent on test results.
- Decoration and making good to be carried out, builders clean and inspections.
- Replace HEPA filters and carry out challenge (DOP) testing
- Final deep/clinical clean and air particle count (By the Board)

This less invasive solution could be carried out in the region of 6 weeks construction time and has an overall duration of between 8 to 10 weeks depending on sign off and procurement.

5.3 What else will Brookfield Multiplex be doing - Full Change Option

We will over the next 2 weeks carry out a feasibility study on increasing the performance of the ward beyond what the currently installed services/building fabric can provide.

During this period we will consider alterations that would be required, including design review of :-

- Duct size
- Plant capability, Air Handling Units, heater batteries and Fans
- Room pressure monitoring
- Spatial constraints for duct work alterations and maintenance requirements in sealed rooms
- Access Maintenance
- Fabric/Lighting/seals

Subsequent to approval/agreement, to minimise the programme, we will progress to a full design while also progressing the procurement of materials on longer lead in times. We understand items to be on a 4 to 6 week lead in period and will express these for best delivery dates. This will take a further 3 weeks including the time for the Board to sign off design.

We would anticipate that to this point 5 weeks will be required.

To achieve a 10 air changes per hour, we anticipate a full strip out of the existing mechanical ventilation system and upgrade of the air handling units which we would be unlikely to install and complete in less than 5 or 6 months from design to completion and tested.

5.4 Why has this happened?

Brookfield Multiplex is reviewing the information set out in the employers requirements associated with the Ward and what specification the design was developed to.

9th July 2015.

SBAR – Ward 6A environment
26/8/19, Microbiology dept QEUH

Situation	Ward 2A in Paediatric haemato-oncology was moved to Ward 6A QEUH in September 2018. This was initially planned to be a short term decant assessed via an options appraisal to enable water control measures to be implemented on 2A. During that time HPS commissioned a review of the ventilation strategy for ward 2A. An external report concluded that the ventilation strategy for 2A was abnormal, placing patients at risk of infection, therefore the decant had to be extended to enable extensive ventilation remedial actions. Given that there were no further cases that met the water incident case definition between September and April, a repeat options appraisal was not undertaken when it became apparent that the decant was to last much longer than at first anticipated. A PAG was held on 3rd June 2019 to discuss 4 cases of Gram negative bacteraemias. An IMT followed on 19th June due to a further environmental bacteraemia, this time a <i>Mycobacterium</i> species which was subsequently found to be related to the water supply utilising whole genome sequencing. The hypothesis for <i>M. chelonae</i> acquisition was exposure to unfiltered water outside 6A, possibly operating theatres. The IMT process is still ongoing and to date there have been 11 confirmed and one possible case of Gram negative bacteraemias since 13th April.
Background	Surveillance of all bacteraemias was put in place when the ward was decanted to 6A. From September to April bacteraemia rates were very low and any Gram negatives were coliforms, i.e. expected species of bacteria and usually endogenous gut flora. From April 2019, bacteraemias secondary to environmental organisms have occurred, some of these meet the case definition from the previous incidents from 2A e.g. <i>Stenotrophomonas maltophilia</i>, <i>Enterobacter cloacae</i>. Others are from rare organisms not part of that incident but of a soil/water type of bacterial species. Examples include <i>Chryseomonas</i> sp, <i>Elizabethkingia miricola</i>, <i>Pantoea septica</i>.
Assessment	Current environmental risks on ward 6A 1. Air changes – essential for dilution and removal of pathogens generated within the room environment e.g.

	from toilet plume, respiratory generated infectious aerosols, and water generated aerosols from taps and drains containing pathogens as well as flora shed from skin such as <i>Staphylococcus aureus</i>. Current Air Changes per Hour is less than 3. SHTM guidance is 10 for neutropenic rooms i.e. less than a third of fresh air turnover required to meet standards 2. Chilled beam technology is in place in each bedroom at the point of supply Chilled beam technology should NOT be used in the neutropenic setting. Infection risks associated with chilled beams : 1. Build up of dust which typically harbours skin organisms, fungi and <i>Acinetobacter sp.</i> This is due to recirculation of air, with no clean to dirty pathway and with essentially the beam functioning as a filter that is not changeable which collects up dust and fibres from the room air. These are requiring 6 weekly cleaning schedule, however they are not designed to be thoroughly cleaned in situ and will require removal under HAISCRIBE conditions to achieve. 2. Water source from a) Condensation b) Leaks from the hot and cold circulating water (known contaminated cold water) c) Dripping water from both can become contaminated with the dust organisms The SHTM guidance states that condensation should not be allowed to occur when these systems are in place. However condensation events have been recorded on numerous occasions throughout the hospital including on 2A and 6A. This allows multiplication and growth of bacteria and fungi, particularly when dripping through collected dirt on the unit. Leaking connections have also occurred which allows water borne organisms from a complex water system to ingress into the room. This poses a risk of <i>Legionella</i> as well as <i>Pseudomonas</i> and other water borne organisms. Water has been seen to pool in the frame of the unit thus causing a significant potential for fungal overgrowth. This chilled beam water system has not been subject to the water quality management system through the water governance structures of the organisation. <i>Pseudomonas aeruginosa</i> and <i>P. oleovorans</i> and unidentified environmental organisms have been grown
--	--

	from the water supply, and from the surface swabs <i>Stenotrophomonas sp</i>, <i>Pantoea sp</i>, <i>Acinetobacter sp</i>, <i>Exophiala</i>, <i>Pseudomonas olerovans</i>, and fungal species. 3. Pressure cascade: recommended pressure of 10 pascals positive pressure to corridor in SHTM, currently there is a nominal 2 pascal positive pressure which is insufficient to ensure robust air movement out of the room, allowing external contaminants to ingress into the rooms from the building void and corridor. Furthermore air sampling studies have shown ingress from risers of heavily unfiltered contaminated air. 4. HEPA filtration: SHTM recommends HEPA filtration of all air supplied to the neutropenic rooms. Currently on 6A there is no HEPA filtration on the supply air. Portable HEPAs are in place in an effort to reduce airborne contamination, but this is not ensuring that HEPA filtered air only is breathed by patients. Contaminated air continues to enter the room and we are reliant on portable HEPA to clean the air 5. Air sampling in the bathrooms has detected pathogenic fungi such as <i>Aspergillus</i> and <i>Mucoraceous</i> mould. Previous issues with mould in the bathrooms was identified and rectified due to weak joins between the shower floor and the wall, however the risk remains as the weak join remains as per original spec – it is only a matter of time before the join is coming apart again. A long term solution to remove the join altogether has not been supplied to date. There is potential for HEPA filters to be placed in the bathroom ceilings, however again, this is a cleaning method for air rather than a HEPA supply. 6. Toilets – toilet plume is a risk as no toilet seat in place. These are currently being rolled out 7. Exposure to unfiltered water ; while all bathroom and bedroom outlets have had point of use filters applied , it has not been possible to place these in the DSR where water is sourced for domestic cleaning . 8. Ceiling: solid ceilings are required to both assist with positive pressure achievement and protection from ingress of water from services in ceiling; however ceilings are tiled and therefore inappropriate for this setting. 9. Play areas; there is no play area and communal toys are
--	--

	situated in the corridor, thus presenting a risk of cross transmission 10. Door entry – no double door or pressure cascade therefore external hospital air ingresses to the unit readily 11. Kitchen hand wash sink is a non compliant size and no POU filters. 12. Prep room – stainless steel sink, not useable due to tap misalignment and therefore clinical hand hygiene sink is being used for prep room functions
Recommendations	1. The decant from 2A was for a short term only and given ongoing environmental risks and recent environmental bacteraemias, a reassessment of the options appraisal is urgently acquired. 2. 6A should be considered to have significant unacceptable levels of infection risk for the immune compromised patients due to the built environment. 3. External peer review from colleagues in Great Ormond Street

QUEEN ELIZABETH UNIVERSITY HOSPITAL

WARD 6A PRESSURE PROFILE

Section 2 – Executive Summary – Ward 6A

Room differential pressures have dropped since previous visit from setup since November 2018. To help improve the room pressures we could assist by several adjustments;

1. Check replace AHU pre and or secondary filters and fan/motor drive belts.
2. *Reduce toilet extract to maintain higher pressures within the rooms by maintaining SHTM03-01 (single room occupancy) compliance by ensuring a minimum of 3 air change rates are maintained.
3. Fit door dropdown seals on the bedroom doors to help maintain room pressure.
4. Replace/fit door seals to help reduce construction door leakage.

*NB: An isolation room WC should be 10 air changes per hour, although these rooms are designed to be single occupancy standard rooms. A clinical decision would be required on this adjustment.

Corridor to external corridor pressures

Pressure cascade from ward 6A to corridor facing ward 6D is +4.6Pa.

Pressure cascade from ward 6A to corridor facing ward 6B is +6.0Pa.

Comments: None

The adjustments made to these bedrooms was to achieve a +ve pressure from rooms to corridor. This was previously achieved. Please see executive summary for corrective actions and recommendations.

The Following document is a Request for Information (RFI) response received by the Scottish Hospital Inquiry from NHS GGC

RFI (Request for Information) 10

Ward 6A of the QEUH: In respect of all perceived problems, defects and issues with the ventilation system within Ward 6A of the QEUH, following building handover in January 2015 to present date.

This response is presented as a chronology, identifying documents to answer to the various sections of 4.1 to 4.7 against each of the work programmes that may in a wide interpretation be considered as “remedial and/or refurbishment works”. We have included works that were undertaken to create improvement in the ventilation however this does not necessarily mean that they were undertaken in respect of a perceived problem, defect or issue.

The response below must be read in conjunction with the documents previously provided which, together with the chronology below, form the full response to RFI 10, Section 4. The responses to RFI 1 6 submitted 10.11.2021, RFI 3.4 submitted on 01.04.2022, RFI 4 submitted 04.04.2022, and much of the response to RFI 7 provide background and detail to the decisions taken to proceed with works; information previously provided has in general not been duplicated in the response below.

Filename	Descriptive comment
	On 26 September 2018 some patients from RHC Ward 2A/B were moved into QEUH Ward 6A and 4B. At the Ward 2A, RHC Incident Management Team on 28 September 2018 a request for portable hepa filtration units is noted. The subsequent meeting on 5 October 2018 of the same group recorded “<i>4 portable hepafilter units have been delivered to Ward 6A for patients stepping down from ward 4B BMT</i>”. This was anticipating that Ward 4B BMT paediatric patients might be stepped down from 4B to 6A. (refer to the Ward 2A, RHC IMT minutes provided in response to RFI 1 6)
	The response previously provided to RFI 1 6, included a “Water and Cryptococcus timeline” indicating that in November 2018 the Cryptococcus Incident commenced. Within Ward 6A, activities undertaken to improve the built environment in response to a hypothesis or considered opinion of that group are tracked in the notes of the Cryptococcus IMT. (refer to responses previously provided to RFI 1 6) Works related to the ventilation system / air quality included: • Deployment of mobile/portable city M HEPA Air Scrubbers • F7 filters on AHUs changed to F9

	• CVG (Ceiling Ventilation Grilles) removed and replaced with a standard ceiling tile • Chilled Beam Units - control adjustments, fitting replacements and cleaning • Installation of recirculation air scrubber fans

Cryptococcus minutes IMT 25.1.19.doc	25th January 2019: Cryptococcus Incident Management Team Already submitted - Part of RFI 1, Qu 6. <i>"Dr. Inkster confirmed that when Ward 6A re-opens there should be a HEPA filter in every patient room with an additional 7 HEPA filters within the corridor."</i>
Cryptococcus minutes IMT 28.1.19.doc	28 January 2019: Cryptococcus Incident Management Team Already submitted - Part of RFI 1, Qu 6.
Cryptococcus minutes IMT 30.1.19.doc	30 January 2019: Cryptococcus Incident Management Team Already submitted - Part of RFI 1, Qu 6. <i>There are currently 26 HEPA filters throughout Ward 6A. Currently awaiting delivery 13 new units and have requested 30 more units which are currently being built. Myra Campbell said Ward 6A could have some of the HEPA filters currently in her ward. Myra will identify the HEPA filters that can be used, but will check with Dr Inkster before any are removed.</i>
ATO101_02558443 RE Crypto IMT.msg	1 February 2019: Email communication update on IMT actions. Advising that Estates Manager is working on calculation / review process to determine what current F7 filter can be replaced with a F8 or possibly a F9 filter. Checks taking place against commissioning figures for the capacity of the AHU fan and motor to ensure sufficient air flow can be achieved.
	F9 filters have a higher 'average efficiency' than F7 filters. When filters were changed filter frames were sealed at the same time preventing air bypass.

Cryptococcus minutes IMT 4.2.19.doc	4 February 2019: Cryptococcus Incident Management Team notes of meeting Already submitted - Part of RFI 1, Qu 6. <i>“Delivery of 13 HEPA filters happened on Friday 1st February. They were taken to Ward 6A to cover every patient room and corridors.”</i> <i>“As soon as facilities get confirmation data that filters can be fitted into air ducts then they will target the air ducts which pose the highest risk first.”</i>
Cryptococcus minutes IMT 8.2.19.doc	8 February 2019: Cryptococcus Incident Management Team notes of meeting Already submitted - Part of RFI 1, Qu 6. <i>“HEPA filters are to stay within each patient room and ward corridors until solution for ward 2A/2B is obtained.”</i>
ATO102_03303562.xlsx	1 March 2019: Estates (internal) Action Plan indicating that F7 filters on AHUs (serving Ward 6A) have been changed to F9 filters.
	From April 2019: CVG (Ceiling Ventilation Grilles) were removed and replaced with a standard ceiling tile. Wards are fitted with Ceiling Vent Grilles (CVG's) which are open vents between the ceiling and the ward corridors. Among the purposes of these grilles are allowing for venting and detection of gas services leaks above the ceiling where there are mechanical joints. Removing the CVGs reduces the risk of particulates moving from the corridor ceiling void into the corridor transfer area and rooms in Ward 6A. The notes of the Cryptococcus IMT Expert Advisory Sub-Group previously provided in response to RFI 7-2, 2.17 provide the narrative on the background and the progress towards a decision to remove the CVG's and replace with a standard ceiling tile. The date when this was achieved is not recorded, however confirmation that was done is captured in the “Report from the Cryptococcus IMT Expert Advisory Sub-Group Unredacted FINAL 2022-04-05.pdf” also submitted in response to RFI 7-2, 2.17.

2019-04-10 7. Notes of Cryptococcus IMT Expert 100419 final.doc	10 April 2019: Cryptococcus IMT Expert Advisory Sub-Group. Already submitted - Part of RFI 7, Qu 2.17.

Leakage from chilled beams Ward 6A.pdf	3 June 2019: SBAR "Leakage from chilled beams Ward 6A.pdf" Already submitted - Part of RFI 7, Qu 2.24
	The chilled beam units used throughout the QEUH and RHC use Chilled Water or Low Temperature Hot Water to control the air temperature provided to the rooms. The air to the chilled beams is provided by the ductwork from the Air Handling Units in the plantrooms. Intermittent "leaks" from the chilled beams have been attributed to thermal movement in the push type fixings of the pipework. In June/July 2019 the replacement of push fit connections with compression fittings in Ward 6A was commenced. On 29 June 2019, across the hospital, there were reports of multiple "leaks". The cause of these was determined as condensation related to the high relative humidity in the ambient air. The chiller control strategy was adjusted to resolve. Quality checks on works to "clean" the chilled beam grilles identified they were not sufficiently cleaned and an alternate methodology was then implemented. This new methodology was implemented in the cleaning of the Ward 6A chilled beam grilles in August 2019. Refer the SHI to the Gram Negative Bacteraemia IMT minutes which provide the record of decision making and progress reporting. "HSE Ventilation IN Progress Tracker v12.pdf" date April 2022 records that "Chilled beam push fit connections changed to compression".

Extract from M and E Clarification Log docx; Signed off vent drawing - ZBP-ZH-XX-PL-524-058.pdf; 20160518 Ward Ventilation Strategy - Issue 3.pdf; Ward Ventilation Design strategy_Dec 09-SP2
 (4).docx

Hi Teresa,

I can confirm that a typical single room with en-suite is supplied with air at a rate of 40 l/s (equating to 3.19 ACH) and an extract derived via the en-suite at 45 l/s. The move away from the requirement in SHTM 03-01 for 6 ACH was agreed by the Board prior to formal contract award, the justification for the proposed variation to that specified and its acceptance is provided in the following attached documents:

1. Ward ventilation design strategy Dec 2009-SP2
2. Extract from M&E clarification log
3. Signed off vent drawing ZBP-ZH-XX-PL-524-058

As can be seen from the clarification log, the board accepted this proposal with the caveat "Negative pressure to be created in the design solution." achievement of the -ve pressure design has been validated by Brookfield's design team in the attached report ref: 20160518 ward-ventilation strategy - issue 3.

If you require any further information or support on this matter please let me know.

Regards

Ian

Subject: Respiratory ward ventilation

Dear both,

Despite numerous requests for information I have not received anything in writing confirming the ventilation spec of the rooms in level 7 Respiratory at QEUH .

I have been told verbally that these rooms have 3 ACH and are at neutral pressure - is this accurate and can I be sent confirmation of this?

I appreciate there is nothing that can be done to remedy this. However, I need to do an infection control risk assessment and put risk mitigating measures in place on the unit .

It would be useful if I could have the same information for the other high risk areas in the hospital : These are; respiratory outpatient clinics , ward 5C , level 4 renal transplant.

Do we know whether the same decision to reduce air changes was made for RHC?

Kind Regards

Teresa

A48946859

Extract from M&E clarification Log (Final Agreed for Contract)

Ventilation:

Board Comment: Ward Air change to be 6AC/HR, currently shown as 2.5AC/HR which is not in compliance with SHTM 03-01.

Status: Agreed

Brookfield Comments: Brookfield proposal as outlined within the bid submission is to incorporate chilled beams as a low energy solution to control the environment which do not rely on large volumes of treated air or variable natural ventilation. All accommodation is single bedrooms and therefore the need for dilution of airborne microbiological contamination should be reduced (rooms could also be at slightly negative pressure to corridor). Providing 6 air changes is energy intensive and not necessary.

Agreed Position: The proposal is accepted on the basis of 40 litres per second per single room (8 litres per second per second) for one patient and four others. Joint review to be carried out between the Board and Brookfield of the energy model to determine any impact on the energy target/BREEAM rating. Brookfield, however, remain responsible for achievement of the energy target/BREEAM, with £250,000 added to the contract sum in this regard. Negative pressure to be created in the design solution.

NSGH WARD VENTILATION DESIGN STRATEGY

Board Requirement

The design requirements for the NSGH states that the summertime temperature limit is 'not to exceed 26°C'.

This exceeds the guidance provided within the draft SHTM 03-01 on the design of ventilation in healthcare premises, limiting the summertime temperature to 'not exceed 28°C for more than 50 hours per year'.

Natural Ventilation

The SHTM allows for the natural ventilation of areas including general wards. In clause 2.3 it states that 'as the motivating influences of natural ventilation are variable, it is almost impossible to maintain consistent flow rates and ensure that minimum ventilation rates will be achieved at all times. This variability is normally acceptable for general wards'.

Through the use of thermal modeling during the bid stage the use of natural ventilation using openable windows was investigated and results showed that the Board's requirement for temperature control could not be achieved. Furthermore, adding additional background cooled mechanical ventilation, at a quantity to balance the ensuite extract rate, still did not achieve the requirement. Other concerns with natural ventilation included patient comfort due to uncontrolled wind driven ventilation and air quality, particularly in winter when windows would be closed.

Therefore, the sole use of mechanical ventilation was explored, again using thermal modeling.

Mechanical Ventilation

The recommended air change rate for single rooms in SHTM 03-01 Appendix 1 Table A1 for single rooms is 6 air changes per hour (ac/h).

Modelling was carried out based on this recommendation, but it was found that the requirement of 26°C could not be met. To try to achieve this, the ventilation rate was further increased, but became excessive and likely to cause draughts to the occupants, poor temperature control and increased energy consumption.

Consideration was then given to a terminal cooling solution, using active chilled beams which provide cooling, heating and fresh air via the primary air supply system. The performance of chilled beams is related to their physical size and thus the amount of primary air supplied from the central air handling plant. The primary air volume will also

provide make up for the extract from the ensuite toilets to achieve a negative inflow of air into the bedroom from the corridor as required by SHTM 03-01 Appendix 1 Table A1.

Using active chilled beams delivers the temperature control requirement, provides individual room control and fresh air, albeit less than the recommendation of SHTM 03-01.

Chilled beams are also an energy efficient solution and save some 9kg/m^2 of CO_2 over that of an all air system delivering 6ac/h, equivalent to about 10% of the hospitals' total emissions.

Conclusion

If natural ventilation could be employed then the air change rates within the bedrooms would be variable dependant on window opening and external conditions, and is rarely likely to achieve 6ac/h.

The recommended air change rate of 6ac/h in the SHTM is considered to relate to the ability to achieve an acceptable internal environment, i.e 50 hours exceedence above 28°C . This could be achieved with 6ac/h of cooled air.

However, the Board's requirement for a reduced temperature makes this solution impractical and the use of chilled beams is the only viable solution, using a reduced quantity of primary air.

Whilst the air change rate is less than the SHTM, at a supply air volume of 30 litres per second it is in compliance with Scottish Building Regulations and also CIBSE codes, giving sufficient fresh air for a continuous occupation of three people at 10-12 litres per second each.

Air changes QEUH - INKSTER, Teresa (NHS GREATER GLASGOW & CLYDE)

Air changes QEUH

Inkster Teresa (NHS GREATER GLASGOW & CLYDE)

Fri 27/05/2016 10:11

To: Peters Christine (NHS GREATER GLASGOW & CLYDE) <Christine.Peters@nhs.uk>; Pritchard Lynn (NHS GREATER GLASGOW & CLYDE) <Lynn.Pritchard@nhs.uk>; Joannidis Pamela (NHS GREATER GLASGOW & CLYDE) <Pamela.Joannidis@nhs.uk>;
Cc: McNamee Sandra (NHS GREATER GLASGOW & CLYDE) <Sandra.McNamee@nhs.uk>; Walsh Thomas (NHS GREATER GLASGOW & CLYDE) <Tom.Walsh@nhs.uk>

Hi all ,

I have had confirmation from Ian Powrie that the single rooms in QEUH have air changes of <3 which is half the recommended 6/hr. In addition the rooms are at neutral pressure and not negative as was intended to compensate for this drop in ACH .

I know Lynn/ Christine that you have put measures in place on the respiratory ward already but we now need to consider what we do for the rest of the hospital. Of particular concern is renal transplant as these rooms should have been designed at positive pressure. Can I suggest the four of us meet up to discuss. I am free from 3pm on Tuesday if that suits at QEUH.

Pamela - I am awaiting confirmation from Ian regarding RHC . I also need to find out the answer to your question Lynn about the retained site

Kind Regards
Teresa

SBAR – Air changes , patient rooms , QEUH
Dr Teresa Inkster, June 2016

Situation	During an investigation into Mycobacterium abscessus cases in Cystic fibrosis patients at QEUH the ICT were alerted to reduced air changes in patient rooms.
Background	Recommended air changes for a single room on a ward are 6 air changes / hour as per HTM 03-01 (Specialised ventilation for healthcare premises). This would not normally have infection control sign off. A decision was made to reduce air changes to 3 ACH/hr in the renal dialysis unit for energy efficiency. This decision was then extrapolated to the rest of the hospital. Sufficient negative pressure of the rooms was not obtained to make this a safe option. Rooms are currently at a neutral pressure. There is therefore both reduced dilution of microbial contamination and escape of air out of the rooms into surrounding areas.
Assessment	Placement of patients with airborne infections in these rooms represents a risk of cross transmission to other patients and staff via the airborne route. High risk areas in the QEUH have been identified as; 1) Level 7 Respiratory wards 2) Outpatient respiratory clinics 1st floor clinic B rooms 77-85 3) Physio department – Room 16 , Ground floor 4) Renal transplant , level 4 5) ID unit , level 5 6) During winter months and respiratory virus season other wards will be high risk
Recommendations	1) Doors to rooms should remain closed 2) For aerosol generating procedures in in-patients 2 hours should be left before non- essential personnel enter the room and before a new patient is admitted. 3) For aerosol generating procedures 2 hours should be left between patients in the outpatient setting 4) Staff should continue to wear appropriate PPE 5) Renal transplant patients should where possible be nursed in ward 4C until 12 months post transplant. 6) ICT should be made aware of any renal transplant patients with PCP. 7) This information should be reviewed in conjunction with the HFS review of isolation rooms. Contingency planning may be required for patients with active pulmonary tuberculosis.

All

It seems to me that there are quite significant implications of this note; I would be keen that we get together to discuss this note and what we need to do about this; I have also alerted Robert Calderwood to this issue; Perhaps we need to set up an urgent meeting to discuss the implications and what we need to do about this asap.

I wonder if you would all be good enough to flex your diaries; In addition, I think David you were going to review how these decisions were reached and also what the thinking was behind the new room designs? I wonder if perhaps one of the project team and perhaps we need some clinical advice from specialists about the implications for patients. However in the first instance can we discuss this please

Tom - further to our phone conversation details of the pressures we checked yesterday are below. We used two methods - a micro anemometer and a smoke test

As per SHTM 03-01 a single rooms spec is 6 ach/hr and a pressure of 0 to negative. My understanding is that to offset the reduction in air changes with chilled beam technology the rooms were to be at a definite negative pressure. In most areas this is not an issue but is problematic for immunosuppressed patients particularly haemato-oncology.

You will note the pressures recorded below. Ward 4C is housing haematology patients and the rooms should be positive. The readings we have confirm that they are but they are not as positive as they should be. This requires more thought.

What I am more concerned about is the readings from 5C/D as these indicate we have rooms at neutral positive pressure. These wards are where we have ID patients including non resistant TB cases. As this is an airborne infection these patients must be in a negative pressure environment. We have PPVL rooms on the critical care floor in the process of being upgraded to negative pressure. These will be used for multi drug resistant TB cases and any query MERs -Coronavirus but there are still several patients with non resistant TB who will need to be nursed in 5C/D. The risk here is not to the patient but to staff and members of the public as the contaminated air is coming out of the room.

As we discussed it would be useful to have a review of these areas. I have had a conversation with Andy re these results and will catch up with you later today

Kind regards
Teresa

Hi Teresa

Thanks for the email. Cameron Raeburn has set up a meeting to take place on Thursday with regards to the recent HSE issues that have been highlighted and resulted in an Improvement Notice, as you are aware.

I will ask Cameron to take into account the information that you have provided with regards to ventilation. I have also copied Morag Gardner who is directly involved with both the HSE requirements and the meeting that will be taking place on Thursday.

I will be on leave over the next 2 weeks and so I will ask Cameron to liaise with you after the meeting on Thursday.

Regards

Kenneth

Subject: [ExternaltoGGC]Ventilation wards 5C and 5D

Hi Kenneth,

I am writing to make you aware of an issue with ventilation in wards 5C/D in QEUH as there is a health and safety issue.

By means of a background, the ventilation in QEUH, with chilled beam technology, was designed to be 3 air changes per hour with rooms at a slightly negative pressure.

Investigation of ventilation in the now decanted 2A/B RHC revealed some matters of concern. I therefore requested other high risk areas on the site be assessed to see if these issues were replicated.

On checking pressures and air direction with my colleague Dr Hood we found there to be varying pressures in the rooms on 5C/D. Some were slightly negative but others were positive. It was not clear to us why there should be inconsistency between rooms on the same ward.

I have discussed with estates colleagues and my understanding is that these pressures have been verified by an external company and they are investigating how to rebalance the system. If this is not possible we will need to determine exactly what rooms are safe for each patient group.

5D is used for patients with TB therefore rooms at a positive pressure represent a risk. The risk is not to the patients in the room or staff entering the room wearing PPE but to others. This is because air is being pushed out of the room into the corridor and ward.

HIV patients, housed on 5C, are immunosuppressed and would benefit from rooms at a slightly positive pressure.

My concern at the moment relates to the potential for staff/patients to have been exposed in 5D and I would welcome your input.

Kind regards

Wilson, Andy <Andy.Wilson@nhs.uk>

Wed 05/12/2018 13:23

To: INKSTER, Teresa (NHS GREATER GLASGOW & CLYDE) <teresa.inkster@nhs.uk>

Cc: Steele, Tom <Tom.Steele@nhs.uk>

Hi Teresa,

We are progressing with the work discussed to review, and improve where necessary, the pressure regimes across a number of wards; 4C, 5C, 5D, 7A & 7D.

As discussed today, following the changes made to the operating parameters for the plant across all of these wards, we have already confirmed that we have been able to achieve the 1Pa negative pressure in the room vs corridor for ward 5C and our next area of focus for balancing work is ward 5D. I am awaiting confirmation from the contractor of what has been achieved in 5C.

As discussed today, you are not certain that a positive environment is correct for all patients in 7A & 7D and will need to get confirmation from clinical colleagues before proceeding so I have put on hold further work to these wards until confirmed.

For ward 4C, we will continue with work to provide as positive an environment as possible but it would be useful to know the minimum positive pressure you would like to see in the room so we know whether simple re-balancing may be sufficient or whether we should progress with consultant reviews of the system to identify what size / power of fan is required to achieve the desired pressure regime. Can you please confirm the minimum positive pressure that would be acceptable for 4C?

Thanks,
Andy

Cc: Walsh, Tom <Tom.Walsh@nhs.uk>
Subject: FW: Airborne pathogen infection control

Dear Tom

I was copied into this email from ID clinicians yesterday. In order to provide assurances with respect to patient safety I need the following;

- Written documentation of the pressures in the rooms in wards 5C and 5D - I thought this had been undertaken by an external company but have been told that this was done in-house
- An understanding of the ductwork configuration and whether the same issues identified in wards 2A/B are present in these wards
- What rebalancing has already taken place
- Any further remedial works required.
- How we ensure that room pressures do not flip from negative to positive – this is very important in the context of airborne infection in that even slightly positive rooms will lead to egress of contaminated air

Ward 5C/D is where we house infectious disease patients where we could expect to see patients with airborne infections including TB, Chickenpox and Measles

Kind regards
 Teresa

Subject: Airborne pathogen infection control

Dear Scott, Anne, Fiona and Colin;

Last week we were informed that estates are investigating the ventilation systems in the Infectious Diseases wards, 5C and 5D. In 2015 the Infectious Diseases team moved to the QEUG in 2015 we were reassured that there would be

2 negative pressure rooms on 1st floor that we would have access to. These turned out to be positive pressure ventilated lobby rooms which are not deemed safe enough to manage high consequence airborne infections.

Once this was realised an interim measure was put in place after meetings with estates, infection control, management and following discussion with our clinical colleagues in GRI and Lanarkshire. It was decided that pulmonary tuberculosis could be managed on 5D with appropriate PPE. Immunosuppressed patients, largely those with HIV, would be geographically separated from those with TB and managed on 5C. Those with a high risk of MDR TB or with an established diagnosis of MDR TB would have to have their care transferred to one of the 2 negative pressure rooms on the GRI site. Any patient with proven MERS CoV would need to be transferred to Monklands negative pressure rooms. This was supposed to be a temporary arrangement while an engineering solution was found to convert the 1st floor rooms to negative pressure.

We understand that the engineering solution for the negative pressure rooms on 1st floor has been problematic and we understand the work has currently been suspended. We have also heard that the basic expected air exchange in the standard 5th floor rooms is not the expected 3 exchanges per hour but that there is a mixture of positive and negative ventilation in different rooms.

There is an immediate patient safety concern as those with airborne infection may be currently housed in a positive pressure room, thus spreading pathogens into the corridor and potentially other rooms. Those susceptible patients e.g. with HIV, on various immunotherapies, neutropenics etc may be housed in negative pressure rooms thus sucking pathogens into their rooms from the corridor. Given GG and C has the highest burden of tuberculosis in Scotland and that we provide the only inpatient infection service for the area, including HIV inpatient care there is a real concern about the ability to safely provide this service at present on the QEUH site.

We are requesting urgent reassurances from estates, endorsed by the Infection Control Lead that patient safety is not currently being compromised due to the ventilation system in the inpatient areas in QEUH.

Kind regards,

David Bell and Erica Peters

Further update

They have ascertained why those rooms are failing (the dampers are closed) – so each room will need to be empty for an hour or so to allow estates access

Then we are confident they too will be negative pressure

Just to confirm our conversation earlier today following a meeting with estates and the lead ICD

Adjustments to the ventilation in 5C have been made such that all rooms are now negative pressure
 Similar work has been undertaken on 5D and the report was due today (I will chase it in the am)
 Currently all rooms except rooms 56 and 54 are negative . Rooms 55 and 53 could not be tested but I suspect may be the same
 So until we hear otherwise sputum positive TB patients should not use those 4 rooms

Fw: Airborne pathogen Infection - INKSTER, Teresa (NHS GREATER GLASGOW & CLYDE)

For clarity the commitment given pre move was that the ID team would have access to two rooms which offered the same level of isolation as those in the Brownlee and although guidance has changed – the rooms met the required building note at the time. They continue to do so and the PPVL rooms with Hepa can continue to be used while we pursue the conclusion of the work to provide negative pressure in MHDU / ICU

To: Purdon, Colin

Subject: [ExternaltoGGC]Re: Ward 5D & 7D rebalance

Hi Colin, yes I was in on the 23rd and rechecked all the rooms that were noted on the original report as dampers closed (MFSD) the rooms were from -ve to -2.5Pa - favourable results, I checked all floors and a selection of rooms and the pressures were the same as the initial report, I completed the report on site but my laptop email stopped working! Hopefully the above detail is okay until I can transfer the report.

Thanks, Ian.

Best regards,

Ian.

Dear Marion,

Further to our discussion this morning I attach the original SBAR I wrote in 2016 regarding air change rates. You will note that level 5 is designated a high risk area.

I have also attached the relevant table from the CDC guidelines. You will note that for 6 hours the time required for removal 99.9% efficiency is just over 1 hour, hence why 2 hours is applied for air changes of 3. If there is scientific evidence being provided to the contrary it would be useful to see this, as I have always worked to the CDC environmental guidance

Kind regards
Teresa

63	-ve	+0.8			

Comments:

-ve = 0 - <1Pa (notionally negative)

+ve = 0- <1Pa (notionally positive)

Any pressure greater than 1Pa is detailed.

Pressure varied as the corridor doors operated, these also differed if patients toilet doors were open/closed this impacts on door differential pressure to corridor.

Several variances slightly change the profile, the door finish also has an impact on the pressure control. The retro fit of door drop down seals would help with this control and stabilise pressures, as fitted on ward 4B.

3. Executive Summary

The fan inverters, as advised by Barkell the AHU manufacturer were set to operate at their max capacity on FLC (Full Load Current) In the case of the AHU serving the floors 5C 124AHU04 & 124AHU05 we set the inverter drives to a max (in hand operation) set point of 56Hz for 124AHU05 and 60Hz for 124AHU04.

The detail shown is with main fan adjustments only, we await a HAI-SCRIBE sign off before commencing with individual ward balancing. The HAI-SCRIBE will cover us for gaining access to VCDs (volume control dampers) located about ceiling tiles, these are located and have been identified on layout drawings to form part of the HAI-SCRIBE.

The VCDs are either in and mostly located in corridor locations, however some are located within occupied bedrooms above suspended ceiling grids.

The next, as discussed actions, would be to alter the main branch VCDs, controlling alterations proportionally to each floor to increase extract volumes within rooms/wards that are to control to a negative pressure and reduce extract volumes to increase rooms/wards where positive pressures are required.

Another action discussed was to attach door drop down seals (as fitted in ward 4B) except we have recommended adjustable seals, as this will aid with the room pressure control on an individual room by room basis, without requiring access to individual rooms and local VCDs.

The initial findings are encouraging and alterations of main branch dampers will support the desired end result.

Going forward I will update and expand on the attached, for transparency of our actions and adjustments. This will also help with the assessment of the next required ward pressure change.

Comments:

-ve = 0 - <1Pa (notionally negative)

+ve = 0- <1Pa (notionally positive)

Any pressure greater than 1Pa is detailed.

Room pressures vary due to toilet doors being open/closed fabric seal of room and door seal to frame and distance from frame to floor. Most bedrooms doors open during survey and these were closed one door at a time to record pressures. This will also have a varying factor to recording room pressures.

Comments:

-ve = 0 - <1Pa (notionally negative)

+ve = 0- <1Pa (notionally positive)

Any pressure greater than 1Pa is detailed.

Pressure varied as the corridor doors operated, these also differed if patients toilet doors were open/closed this impacts on door differential pressure to corridor.

Several variances slightly change the profile, the door finish also has an impact on the pressure control. The retro fit of door drop down seals would help with this control and stabilise pressures, as fitted on ward 4B.

3. Executive Summary

The fan inverters, as advised by Barkell the AHU manufacturer were set to operate at their max capacity on FLC (Full Load Current) In the case of the AHU serving the floors 7D 123AHU04 & 123AHU05 we set the inverter drives to a max (in hand operation) set point of 51Hz for 123AHU05 and 56.5Hz for 123AHU04.

Another action discussed was to attach door drop down seals (as fitted in ward 4B) except we have recommended adjustable seals, as this will aid with the room pressure control on an individual room by room basis, without requiring access to individual rooms and local VCDs.

We did open a MFSD (Motorised Fire/Smoke Damper) in the toilet next to the mechanical riser that we found closed serving 123AHU04 Extract east side of Tower D 6th Floor

Minutes QEUH – Isolation Rooms

Project: QEHB & RHC

Date & Time: Tuesday 31st May 2016 at 2:00pm

Venue: Meeting Room 5, New FM & Lab Medicine Building, QEUH

Invitees:

Ian Powrie (IP)	NHSGGC Sector Estates Manager
Douglas Ross (DRo)	Currie & Brown
David Wilson (DW)	Brookfield Multiplex
John McEwan (JMcE)	Hulley Sfm
Stewart McKechnie (SM)	TUV-SUD
Dave Ramsay (DRa)	Capita

Apologies: **David Loudon (DL)** NHSGGC Director of Facilities and Capital Planning

Purpose Of Meeting: Due to recent formal concerns raised by ID Physicians & ICD colleagues at QEUH, NHSGGC wish to seek confirmation from Health Facilities Scotland (HFS) on certain matters relevant to SHPN 04 Supplement 1. These are contained in Questions 1 and 2 of "HFS Isolation Room Status" document with Question 1 having been submitted to HFS. In advance of Question 2 submission, DL requested Supervisor to comment on Question 2 which highlights variations to SHPN 04 Supplement 1. The Team therefore requires to be unified in support of the submission and supporting information. Question 2 forms Part 1 of the agenda. IP and JMcE met on site on 25th May 2016 to view Isolation Rooms and Supervisor's (JMcE) Notes from that inspection forms Parts 2 and 3 of the agenda which includes relevant design and technical matters pertaining to the proposed submission.

Item	Minute	Action
1.0	PROPOSED SUBMISSION PACK TO HFS	
1.1	HFS Isolation Room Status In this document NHSGGC has prepared 2 Questions to be raised with HFS for confirmation. IP confirmed that the following Question 1 has now been forwarded to HFS. IP advised that HFS at this stage does not require detailed information of what has been provided in the Isolation Rooms at QEUH, but the likelihood is that HFS will be aware of Isolation Room layout. <i>Question 1:</i> <i>Is the ventilation design criteria set out in SHPN 04 supplement 1: Isolation Facilities in Acute Settings As detailed in Table 1: Isolation Suite – Ventilation Parameters and Sheet 2: New build single room with en-suite facilities and bed-access lobby (isolation suite), suitable for safe nursing of patients with the one of the following conditions?</i> 1. Multi Drug Resistant TB (MDRTB)? 2. MERS? 3. H1N1? In advance of NHSGGC issuing the following Question 2 to HFS, the Team requires to be unified in support of the submission of Question 2 and the supporting information for the main variations from SHPN 04 supplement 1. <i>Question 2:</i> <i>If the above design criterion is suitable for safe nursing of patients with any one of these conditions please advise if the following design variant is equally suitable?</i> <i>See attached schematic ref: ZBP-XX-XX-SC-524-871, along with a set of commissioning documents for a representative Critical Care Ward (CCW), isolation room ventilation arrangement within the QEUH.</i> <i>The following variations should be noted:</i> 1. The main extract is located in the isolation room. 2. The alarm system to the nurse's base was deleted, including: • Room Lobby pressure gauge alarm. • The extract air flow switch; alarm to the nurses' base. • The supply air flow switch; alarm to the nurses' base. 3. The transfer grille between the isolation room and the en-suite was deleted. Discussion centred on the design development process for the isolation room layout and ventilation design. DW explained that the original ventilation schematic design Drawing No ZBP-XX-XX-SC-524-707 dated 2010 for the Isolation Room Suite showed the extract located only in the En-Suite ceiling. In 2012 the ventilation schematic design submitted by Brookfield (Dwg No ZBP-XX-XX-SC-524-871) showed extract located in both the Isolation Room ceiling and the En-Suite ceiling. SM pointed out that there would have been several iterations of the drawing schematic during that period indicating that there presumably would have been discussions among the parties and reasons for developing the design. DW agreed that Brookfield would research into the process of the design development of the schematic design for the ventilation of the isolation Room Suites (Refer Action 4.1). Brookfield to track the Design Development of the Isolation Room Layouts to inform how the following were decided: - extract grille located within Isolation Room ceiling and En-Suite ceiling; no transfer grill on the En-Suite door; the location of the bed.	DW

2.0	IP/JMcE INITIAL REVIEW OF SOME ISOLATION ROOMS ON 25TH MAY 2016 AND MATTERS DISCUSSED	
2.1	CCW-163 Bed 50 would be used as an exemplar to understand installed standard v Compliance (Also taking into consideration any PMIs or Derogations). JMcE advised that Isolation Room Suite CCW-163 Bed 50 should be used as the exemplar for understanding the installed layout and ventilation design in comparison with SHPN 04 Supplement 1:- CCW-163 (Lobby); CCW-164 (En Suite); CCW-165 (Single Isolation).	Note
2.2	Provision of "all" available validation documentation provided under the construction contract for Bed 50- DW to collate all validation documentation for the Isolation Room Suite as Item 2.1.	DW
2.3	Provision of "all" available verification documentation provided under the FM contract for Bed 50 IP explained that Estates are currently verifying the Theatres and will shortly be commencing verification of the Isolation Rooms. IP confirmed that H&V Commissioning Services Ltd were doing verification. JMcE requested the standard pro- forma that is being used for verification so that he can review.	IP/JMcE
2.4	Confirmation on what design standards the rooms are built & validated to Discussions centred on the requirements of SHPN 04 supplement 1.	Note
3.0	SUPERVISOR (JMcE) INITIAL OBSERVATIONS (where access was gained) USING SHPN 04: SUPPLEMENT 1 AS REFERENCE	
3.1	Room pressure was sitting at 8pa. This was at the magnehelic and no true readings were taken to verify. Range should be between 10 and 12 pa. (Appendix 2 Acceptance Testing) DW confirmed that tests undertaken proved that a positive pressure of 10 Pascals between entry lobby and door had been achieved. JMcE requested confirmation of pressure readings taken between Isolation Room and Lobby and taken between Isolation Room and En-Suite. DW confirmed he would provide. DW to issue test results to Supervisor for review.	DW/JMcE
3.2	No Alarms installed to indicate to clinical team of potential ventilation issues or remote alarm at nurses stations. Also demonstrated by low pressures having no indication (4.22) SHPN 04 Supplement 1 Section 4.22 states: - "Audio and visual alarms must be located at the entrance to the lobby and bedroom to warn nursing and maintenance staff of potential unsafe conditions. Continuous monitoring should be provided with remote indication at nurses stations, interlinked to the Building Management System with time delay (adjustable by Estates personnel) to take account of running-up of standby motors or damper operations or other plant items that may take time to open or close." DRo explained that no alarms are provided to nurses' station as these were omitted by the Board in PMI 169 Nurse Call Interface which confirmed requirements of Nurse Base Panel and stated "monitoring bedroom pressure, not required". This was issued following a visit by Lead Nurse on the project and other project team members visiting example hospital in London. DW confirmed that pressure monitoring is linked to the BMS and alarms display on the main BMS control panel in accordance with the BMS specification.	Note
	PMI 169 states: - "Description The Board confirm their nurse call interface requirements for the Adult & Childrens Hospitals as per the attached document. Instruction Incorporate the attached interface requirement into your design development process for the nurse call system." Attached interface requirement states:- "NURSE CALL INTERFACE REQUIREMENTS Following static workshop and visit to Royal London Hospital we have agreed that we need the following items integrated with Static system: - Nurse call, Door access, Fire alarm, Medical gas alarm, PTS notification, Bedroom temperature notification, Control of 3rd party TV from patient handset i.e. static handset capable of operating as TV remote with infrared on static bedhead. We have discarded the following systems which they have used in RLH Bedroom pressure We have also discarded the following applications offered by Static systems as part of their presentations Patient information details, Patient "wandering" system, Voice communication for patient to staff calls"	
	It was discussed that the PMI concerns the Nurse Call interface requirements and does not appear to specifically instruct the deletion of the Audio and visual alarms.	Note
	Brookfield to track the Design Development process consequent to PMI 169 to inform on the deletion of alarms.	DW
	With DRo agreement DW to obtain a quotation for providing audio and visual alarms and forward to DRo.	DW/DRo
3.3	The pressure stabiliser was not operating correctly. With corridor door open top blade remained open. Bottom blade appears to have no status change when doors are either open or closed.(4.21) Brookfield to investigate and also forward pressure stabiliser testing and commissioning information to Supervisor.	DW

Hi Marion,

This email trail really illustrates the urgency of the need for a patient placement policy that is grounded on an evidence base of the rooms as well as clearly explained and embedded surrounding administrative processes and actions in event of failures. This is something Teresa and I have been pursuing since June 2015 and is still not satisfactorily sorted. My colleague Pauline Wright was so concerned about the situation she faced that she phoned me at 3 am on Monday morning even though I was not on call as she knew I would have some understanding of the issues. Unfortunately I was not able to give an answer other than a risk based approach to an unknown entity. Thankfully the case was not a MERS case, and joins a long list of cases which had they been "the real thing" would not have gone well.

kr

Subject: RE: [ExternaltoGGC]QEUH Patient Placement

Thanks Pauline, Teresa, Al

With regard to the RHC, the last information I have is regarding issues I raised in September following a chicken pox case. A table was circulated but did not reflect what I found in reality on the wards as per attached emails. We have not had any updates since then. The PPVL rooms remain with substantial design differences from published validated design with no evidence of equivalence that I am aware of – this pertains particularly to the lack of negative pressure of en-suite to room, and the location of the extracts in the bedroom, which is not in the SHTM published design, as well as reduced ACH in the ensuites.

It would be excellent to have a quality assured, document controlled patient placement policy with live updates if issues emerge (previously had dampers blocked, AHU failures, leaking rooms) completed for both Paediatric and Adult settings for

1. Infectious patients
2. Immunocompromised patients
3. Infectious immune compromised patients

I agree the WHO warnings are helpful in renewing the focus.

Kind regards

Christine

Subject: [ExternaltoGGC]Re: [ExternaltoGGC]QEUH Patient Placement
 Hi Pauline

The need for the patient placement policy was handed over by me when I resigned and we raised it several times in meetings with diagnostics senior management

I had a draft document in place but was unable to finalise due to the outstanding issues with the PPVL rooms delineated in the HFS report. There was an action for the facilities director at the end of August to take this aspect forward. These rooms were not built to specification in that they had modifications, and we have yet to establish what exactly they can be safely used for.

Perhaps in the meantime the IPCT could issue Comms on where the negative pressure rooms are within QEUH/RHC and confirmation that validation is satisfactory. Given the situation with a novel coronavirus and WHO instructing hospitals worldwide to prepare we need this information clarified urgently

There were 4 negative pressure rooms signed off by me in QEUH but that was some time ago and it would be important to check with estates that there have been no issues with these rooms including whether there have been any subsequent validation reports issued, requiring ICD sign off

Subject: Re: [ExternaltoGGC]QEUH Patient Placement

Hi Al,

Thanks for the response, and for Erica's input. The main issue is with negative pressure rooms in QEUH. I'm worried about relying on historical information / emails to make decisions about patient placement when there is nothing in writing. This happens not infrequently and we need the most up to date information to make the right decision.

My understanding is that the patient on Sunday night was in room 4 (SHDU1) rather than room 24, which Erica mentions in her email (cut and paste to the end of this email).

Teresa - can you comment?

Thanks

Pauline

Pauline

Thanks. This was raised at AICC today.

A draft document has identified the rooms in RHC and work is underway, and hopefully will be completed in short order.

Cheers

Al

Subject: [ExternaltoGGC]QEUH Patient Placement

As you know we have had several meetings relating to working as an ICD / giving IC advice out of hours as a Microbiologist at QEUH.

One of the issues we raised was the lack of an up to date patient placement policy based on validation data and we were assured that this would be made available as soon as possible. There was a recognition that this document would need to be dynamic, taking into account the ongoing work at this site.

I was called at 3am today by my ID colleague regarding appropriate patient placement for a patient under investigation for MERS coV.

Unfortunately the negative pressure rooms that I was aware of, rooms 43 and 44 were not available (one has an MDR TB case and the other a patient with complex respiratory problems who could not be moved). My decision was that the PPVL room that the patient was in (HDU1 room 3) was the next best thing and advised the staff nurse to keep the patient there. She informed me that HDU1 room 4 has now been converted to a negative pressure room and that the nurses are checking the pressures daily and they are sitting between -8 to -12.

I changed my advice on the basis of this information and advised the patient be placed in HDU1 room 4.

I am not an ICD but as a Microbiologist giving out of hours Infection Control advice I need to have the most up to date information to do this.

I am concerned about the potential risks to staff / patients by putting the patient in inappropriate accommodation. In addition, every time this happens, an unnecessary amount of nursing and medical time is spent trying to get this information instead of being able to give clear unambiguous advice and allow nurses and clinicians to get on with their jobs.

I might have missed an email communication about this and I apologise if that's the case but can you confirm to me if HDU1 room 4 is now a negative pressure room?

Can we have an up to date list of the current negative pressure rooms in QEUH and RHC?

Thanks for your help

regards

Pauline

Subject: FW: negative pressure rooms

Hi,

As discussed at the AICC today here is the email I had from TI last year. Clearly there are challenges using a room with no en suite if this is the 3rd room that was highlighted on Sunday night. I know that Teresa examined these reports carefully and as such I am confident in the 2 current rooms assuming appropriate checks via estates. I welcome the ventilation placement document that is coming-I presume I will see it before approval via the AICC? There were also rooms signed off in Childrens by the same company around the same time. I don't have any details of this and indeed no copies of the independent report but Teresa will have all of this.

Hope this helps.

Subject: [ExternaltoGGC]negative pressure rooms

Hi Erica

Just to let you know that I have signed off the validation reports for the 3 negative pressure rooms in critical care. The rooms are 43 and 44 and 24 . Note 24 has no en-suite. All meet the requirements for pressure, air changes and have hepa filtered extract.

On failure they will alarm centrally and at the nurses station. Daily records of pressures should be logged (Iain Thomson is aware of this)

The IPCT are working on a patient placement guide as there are now two different types of room in use , negative pressure and PPVL.

There will also be work done to assist with the interpretation of the pressure gauges with the addition of positive and negative pressure signage (at the moment it is red/green colour only)

Let me now if you have any queries

Kind regards

Teresa

Short Report

Potential infection control risks associated with chilled beam technology: experience from a UK hospital

T. Inkster*, C. Peters, H. Soulsby

Chilled beam technology

Energy efficiency

Infection control

SUMMARY

Energy efficiency technologies are now a feature in hospital design, with active chilled beams an example of one in use worldwide. Such innovations have clear benefits but there is a paucity of information with respect to any infection control risks. We describe our experience of chilled beam technology from one of our hospitals where we faced challenges with cleaning and episodes of water ingress including condensation. We highlight the importance of infection control risk assessment in relation to new technologies and the implementation of appropriate risk mitigation.

Introduction

While active chilled beam technology is in use in hospitals globally including Scandinavia, Australia, and USA, their introduction has been largely driven by energy-saving advantages [1]. Active chilled beam technology delivers fresh air to the patient bedroom and is designed to integrate into suspended ceiling systems. Primary air from the supply ducting passes through nozzles into the room. The air movement creates low pressure and draws air back in from the room over the cooling coils. This is termed secondary (entrained) air and mixes with the primary air to be redelivered through diffusers (Figure 1).

In addition to energy conservation, advantages include thermal comfort and quiet operation [2]. Acknowledged disadvantages are the production of condensation and cleanliness

issues [2]. Furthermore the large amounts of bedding used in healthcare settings can lead to the abundance of lint, which can become trapped within the beams [2]. There is a paucity of published data on infection control risks of chilled beam technology with no infection outcome-based clinical trials. Concerns remain regarding the impact of the recycled pathway of airborne pathogens intrinsic to the active chilled beam concept [3,4]. The American Society of Heating, Refrigerating and Air-Conditioning Engineers (2017) notes that chilled beams should not be used in intensive care units, protective isolation or source isolation rooms, toilets, procedure rooms, delivery rooms, endoscopy rooms, or clean rooms due to 'cleaning difficulty and potential for build-up of contamination'. The recirculation within the room interferes with the concept of a clean-to-dirty pathway for clean diluting air to remove pathogens from the contaminated air. There is potential for recirculation of pathogens within the breathing zone of patients and staff but this is an area of active research with computer modelling and other technologies and may depend on factors such as aerosol size, other heat sources in the room and human plume influences on air movements [5].

Figure 1. Active chilled beam technology. From: <https://tacoadvancedhydronics.wordpress.com/category/radiant-cooling-chilled-beams/>.

Current UK and Scottish Health Technical Memorandum guidelines for ventilation in healthcare premises are non-specific and give little guidance as to the suitability of chilled beam technology within healthcare premises [6]. However, the neutropenic and source isolation room concept are incompatible with chilled beams by token of the mandatory unimpeded clean-to-dirty pathway. Where chilled beams are in use in hospitals, guidance states that control settings should ensure that external components of the beam are always above the dew point. With reference to cleaning, access for cleaning and the impact of maintenance requirements should be considered [6]. We would recommend that water safety groups include chilled beam technology as a water source and that these are identified as a risk during the design phase as well as during maintenance. Our hospital has 1677 beds with active chilled beams installed in all patient rooms apart from the critical care and bone marrow transplant units.

Methods

Since our hospital opened in 2015 we have made a number of observations in relation to chilled beam technology which may have infection control implications.

Results and discussion

Cleaning

There have been issues with both access to clean and cleaning frequency. This is a clear disadvantage to the technology in a large hospital. The risk is intrinsic to the design which relies on entrained air from the room space, carrying fibres, skin squames and aerosols passing over the fins of the coils to be cooled/heated. This particulate matter tends to collect and stick to the metal (Figure 2). Others state that as the fin surfaces of an active chilled beam unit are relatively well gapped, dust and dirt particles tend not to bridge the fin surface; this does not reflect our experience [7].

The models in use in our hospital are not of the kind that allow easy removal of the entire beam for full-scale cleaning and decontamination. Cleaning is cumbersome and required on

a six-week rotation due to visible build-up of dust, despite manufacturers suggesting six months to yearly. Access to clean can be problematic when patients are occupying the room, as the chilled beam is situated directly above the patient's bed. High patient turnover makes chilled beam cleaning impracticable as part of the standard discharge clean.

No filter is present, so all recirculated air will either carry with it the pathogens back into the room or deposit on to the beam. This poses an even greater risk when condensation drips

Figure 2. Photograph of chilled beam.

Acinetobacter sp.
Paenibacillus pabuli
Klebsiella pneumoniae
Psychrobacter phenylpyruvicus

through the accumulated dust, as has occurred on several occasions.

Surface swabs from the chilled beams in our hospital have grown multiple organisms (Box 1). These include: (i) skin commensals in keeping with skin squame contamination (raising the possibility of meticillin-resistant and -susceptible *Staphylococcus aureus* also being present and recirculated); (ii) fungi, in keeping with moisture and a carbon source being present in the collected dust; (iii) enteric organisms: in keeping with possible airborne particles of bacteria entering into patient room from toilet and collecting on beams; (iv) environmental Gram-negative bacteria, in keeping with circulating moisture- and dust-borne environmental organisms. Surface swabs were undertaken in one of our general wards following reports of leaking from the chilled beams and observations of dust. These were plated directly on to blood agar, cysteine–lactose and electrolyte-deficient (CLED) agar and Sabouraud plates. In total, areas of the chilled beams from 19 rooms were swabbed. Prior to cleaning, 22 out of 49 (45%) samples were positive. In the two weeks post cleaning, four swabs out of 42 were positive (9%).

This is evidence of the potential biohazard posed by pathogens in the accumulated dirt on the fins of the beam and in keeping with the theoretical risk of airborne pathogens stagnating in the beam instead of being removed from a clean-to-dirty pathway. The likelihood is that as time goes on there will be an increasing bioburden of pathogens building up on the coils presenting an increasing hazard, particularly when combined with condensation events but not restricted to these [5].

Condensation, water leaks, and water contamination

Condensation should not occur on chilled beams and this is a prerequisite for safe functioning in healthcare [1,5,8]. The design and monitoring should be set up to eliminate this risk. Riffat states that ‘when the panel surface temperature is lower than the dew point of room air, condensation on panel and pipe surfaces occurs, which can lead to damage from dripping water

and an unacceptable room air condition’ [1]. This is potentially serious in healthcare settings, particularly with immunocompromised patients. Condensation encourages mould and bacterial growth posing an infection hazard even in small amounts [9]. The degree of hazard depends on the bioburden, the environmental conditions, patient characteristics and effectiveness of the air change dilution effect. We have noted frequent condensation events: most have involved two or three beams in one ward area at a time, but on one occasion 106 rooms throughout the building were affected at the same time. It is not clear if this is due to temperature settings being too low for the dew point or if the dehumidification was planned to be in the air handling unit and is not present in some. Alteration to the dew point to operate above it has been undertaken to mitigate this risk and we have not been made aware of any further issues.

Our experience is not unique, with condensation issues being documented outside healthcare settings in office buildings and a school [10]. These were due to leaks in the duct system preventing sufficient air from reaching the beams [10].

As chilled beams use a water supply system within the hospital, with potential for leakage into clinical areas, the water supply requires temperature monitoring and attention to biocide usage if the water becomes contaminated. The circulating water system poses a *Legionella* spp., *Pseudomonas* spp. and other waterborne pathogen risk.

Leakage of supply water in our hospital has occurred from fittings. This phenomenon is supported by microbiology testing which isolated *Pseudomonas oleovorans* from the beam water system and from swabs from the leakage, external to the beam. This is also crucially backed by a history of water ingress to rooms. Whereas condensation on the beam causes ‘indoor rain’ as tiny droplets of condensation coalesce on the fins and fall into the room, leakage from the piping drips into the rim and drips from a corner in a gravity-directed pathway with the fins remaining dry [7]. *Pseudomonas aeruginosa* has also been isolated from the circulating water in our hospital chilled beam system.

There is no prospectively designed clinical trial based on infection rates that would give evidence for suitability of the use of this chilled beam technology in healthcare settings. Comparison for the UK context would need to be between full fresh air supply with and without chilled beams with standard cleaning methods and measuring healthcare-associated infection rates prospectively. The basis for the advantage of the chilled beam system in the published validation based on computer modelling and prototype testing was that conventional air-conditioning in hospitals included recirculation and indefinite pressure regimes, which is not the starting point in the UK [5]. The validation did not consider infectious aerosols emitting from a patient or infectious doses of various pathogens, nor did it include a comparison of different air change rates.

The proper functioning of a chilled beam system has been described as a balancing act, with temperature, humidity, volumes of outside air and occupancy all playing a role. Hospitals using chilled beam technology should be aware of the potential issues with access to clean, cleaning frequency, and the possibility of condensation or water leaks and subsequent risks from contaminated dust and water. Staff should be encouraged to report any condensation or water leakage events. Chilled beams should be included on a cleaning

schedule and frequency should be determined according to levels of dust build up. Infection control teams should consider chilled beams as a potential environmental source when investigating incidents/outbreaks.

A limitation of our report is that our experience is based on observations from a single centre only and may not reflect experience elsewhere. Further studies are required to delineate the infection control risks associated with such energy-saving efficiency methods which are likely to feature more commonly in future hospital builds.

In conclusion, when designing new hospitals, consideration should be given to the potential infection control risks associated with such energy-saving initiatives, with early involvement of the infection control team to ensure that risks are fully delineated and risk mitigation measures implemented. We would value more detailed reference to chilled beam and other energy efficiency technologies within national specifications for healthcare premises.

A	SUPPORTING DOCUMENTATION
----------	---------------------------------

1.0 GENERAL INTRODUCTION

Purpose of Document

The manufacture, supply, installation, wiring, setting to work and commissioning of the works described in this document shall be undertaken by the Mechanical and Electrical Contractor and is referred to in this document as "Sub-contractor".

To carry out the development of the design, the Sub-contractor shall obtain the necessary supporting documentation including but not limited to that listed in Appendix A.

This specification shall be read in conjunction with all other mechanical and electrical engineering services specifications and the Architectural drawings.

2.0 SCOPE

The scope of work covered by this Specification shall include the following:-

- Ventilation System, including:-
 - Kitchen extract equipment
 - Fan coil units
 - Variable air volume terminal units
 - Local air conditioning systems
 - Air ductwork and ancillaries
 - Air handling units
 - Fans
 - Air filtration
 - Heating and cooling coils
 - Heat recovery
 - Air treatment
 - Silencers and acoustic treatment
 - Air terminal devices

3.0 SPECIFIC EXCLUSIONS

The following is specifically excluded from the scope of this Specification:-

- BMS and automatic control systems
- Insulation
- Louvres in external façade
- Kitchen canopies/hoods

4.0 INTERFACES AND DEMARCATIONS

The Ventilation Systems shall be provided as a complete working system serving the Adult and Children's Hospitals.

The Sub-contractor shall provide information to other parties for power supplies, controls and fire alarm system interfaces.

5.0 APPLICABLE STANDARDS

All elements of the works shall be in accordance with the requirements of current legislation, regulations and industry standards unless otherwise stated.

The Ventilation System shall accord with all appropriate Hospital Technical Memoranda, Codes of Practice and relevant British and European Standards and Appendix A.

The equipment supplied shall conform to all relevant standards and regulations in force. The equipment shall be supplied with relevant Declarations of Conformity to certify compliance with the EMC directive 89/336/EEC-92/31/EEC and the Machinery Safety Directive 89/392/EEC-91/368/EEC-93/44/EEC. Also the equipment and installation shall comply with all relevant statutory requirements in force at the time:

6.0 DESIGN CRITERIA

LV power characteristics: 400/230 V, 3-phase, 50 Hz, 230 V, 1-phase, 50 Hz.

External Design Conditions

	Winter	-6°C sat
	Summer	26.2°C db 18.5°C wb

Primary Chilled Water Operating Pressure	3.0 Bar
Secondary Chilled Water Operating Pressure	<i>Refer to pressurisation plant schedule</i>
Limiting noise criteria <i>at site boundary</i>	<i>Refer to Acoustic Consultant's Report</i>
<i>Room noise criteria</i>	<i>Refer to Acoustic Consultant's Report</i>

For ventilation/air change rates *used in the design*, the Sub-contractor shall refer to the ADB sheets.

7.0 LIAISON

The Sub-contractor shall include for liaison with:-

Health and Safety Professionals. As well as the Health and Safety requirements of this specification, the Sub-contractor shall include for close liaison with Health and Safety professionals including the Hospital's Health and Safety Advisors and the CDM Co-ordinator and shall comply with the CDM Regulations and all Health and Safety Regulations.

The Contractor. The Sub-contractor shall liaise with the Contractor through whom all communications must flow. Drawings and other documentation shall be available via the Contractor. The Sub-contractor shall include for liaison with members of the Contractor's team with an interest in the planning and administration of the Ventilation System.

Other Specialist Sub-contractors. The Sub-contractor shall liaise with other specialist Sub-contractors as necessary to ensure that all interfaces and co-ordination between the Fire Detection and Alarm System and other systems are allowed for. This shall include but not be limited to:-

- Building Management System specialist
- Fire Alarm and Detection specialist
- Other disciplines for co-ordination
- Fire Protect Systems specialist
- Kitchen Specialist

The Hospital. The Sub-contractor shall include for liaison in conjunction with the Contractor with members of the Hospital's team with an interest in the planning and administration of the Ventilation System.

The Architect. The Sub-contractor shall include for review of the Architect's plans and elevations and shall liaise as necessary with the Architect to assist with the production of these drawings. The Sub-contractor shall ensure that the plans and elevations are co-ordinated with the Ventilation Systems, in terms of such issues as space and access. The Sub-contractor shall provide all services input into the reflected ceiling plans for review to the Architect.

The Fire and Risk Engineer. The Sub-contractor shall follow the recommendations of the Fire and Risk Engineer in the production of the drawings. This shall include a review of the Fire Strategy and other documents when locating fire dampers, smoke dampers and the requirement for fire rated ductwork.

Building Control. The Sub-contractor shall liaise, with and adhere to, the requirements of the Building Control Officer.

Any other member of the Project and Trust teams concerned with the planning and administration of the Ventilation System.

8.0 SYSTEM DESCRIPTION

The mechanical ventilation and air conditioning systems shall comply with HVAC DW144, 154, TR19, BS 5726 (updated), and descriptions and requirements set out below.

8.1 Background to Ventilation and Air Conditioning Installations

The building is largely sealed with limited openable windows in order to control the internal environment within the spaces and limit the impact of odours from the Scottish Water works adjacent to the site.

The Hospital shall be mechanically ventilated:-

- Throughout all internal rooms that have no access to natural ventilation
- Perimeter areas where mechanical ventilation is required for clinical reasons
- Perimeter areas where mechanical ventilation is required for operational and environmental control reasons
- Deep plan perimeter areas where necessary to assist the natural ventilation

The various departments to match their function shall be served by a number of ventilation air handling systems.

In general, each air handling system shall be served by packaged air-handling units containing all components necessary (e.g. fans, coils, filters, etc.) to provide the correct environmental control of those spaces/rooms served.

Active chilled beams and fan coil units shall also be provided for comfort cooling in areas where there is a need for separation or where high heat gains make these a more appropriate choice of systems.

Various types of room are included within this project and are described elsewhere. These are:-

- Wards
- Isolation rooms
- Outpatient type departments
- Operating theatres
- Critical care departments
- Comfort cooled areas (e.g. diagnostic imaging)
- Catering facilities
- Safety cabinet extracts
- Computer rooms and data hub rooms

Carbon Target

The hospitals have a stringent carbon target of 80kg/m² per annum and the engineering services have been designed with this strictly in mind. The Sub-contractor shall not deviate from the

proposed designs without consulting with the Contractor and providing evidence on how the deviation impacts on energy usage and hence the carbon target.

Fan Motors

All fan assemblies shall incorporate fan impeller and motors selected to provide the most energy efficient solution conforming to Section 6 regulations and shall be fitted with IE2 efficiency motors to EN 60034-30:2009 as standard, and suitable for operation in ambient temperatures of 40 degrees C.

System Resistance

The carbon target of 80kg/m² per annum requires that, for example, system pressure loss is limited to reduce fan power.

The detailed design calculations for fan resistance have been based on assumed pressure drops through in-line components which are stated in the specification or equipment data sheets. The Sub-contractor's selection of components shall ensure that the pressure drop of a component does not exceed that assumed in the calculations. The Sub-contractor shall also take care in finally detailed the ductwork routes to avoid potential causes of high pressure drop that may have a detrimental effect on ultimate fan performance. Upon completion of the Sub-contractor's installation drawings the Sub-contractor shall recalculate the whole system pressure drop, including all components to verify that the design calculated pressure drop has not been exceeded. For the purposes of calculating the system resistances the following allowances have been made in the figures in the equipment schedules:

Grille	25 Pa
Dampers	20 Pa
Heater Battery	20 Pa
Louvre	25 Pa
Plant Room Attenuator	50 Pa
Cross Talk Attenuator	25 Pa
Cowl	50 Pa
HEPA Filter	450 Pa

All rectangular radiused bends: $r/w = 0.5$

All circular radiused bends: $r/d = 1$

System performance

The Sub-contractor shall supply and install services and equipment to perform as per specification.

The Sub-contractor shall submit details of all mechanical equipment for comment and place orders in a timely fashion to ensure delivery as per programme.

Where a particular manufacture is specified, the Sub-contractor shall include for that manufacturer.

Where considered appropriate, provide for equivalent standard alternatives to be offered for consideration.

This must be done in a timely manner and the Sub-contractor shall provide all details including but not limited to:

- Detailed description
- Cost comparison
- Technical comparison
- Thermal comfort comparison
- Carbon emission and energy usage comparison
- References to standards
- References to SHTM/HTMs

Completion

The Sub-contractor shall protect the system from damage or interference during the works.

The Sub-contractor shall test, and clean the system as per TR/19.

The Sub-contractor shall submit O&M and record information via Zutec.

The Sub-contractor's defects and liability period shall be as the contract prelims.

940 OPERATING TOOLS

- Tools: Supply tools for operation, maintenance and cleaning purposes.
 - Quantity: 2 sets.

T51 CLIMATIC CEILINGS AND BEAM SYSTEMS

GENERAL

In clinical spaces and bedroom accommodation local heating and sensible cooling, where required, is to be provided via 4-pipe ceiling mounted enclosed active chilled beams. The devices shall be complete with dedicated controls enabling temperatures to be varied within each treated space.

In circumstances where sensible cooling units cannot meet the heat gains, then fan coil units are to be used.

The controls shall comprise of local room mounted temperature sensor/controller operating 2-port electrically operated valves in response to user inputs to raise or lower the room temperatures. The controls shall incorporate sequencing to avoid simultaneous heating and cooling to minimise energy input.

The emitters shall be provided with their own dedicated chilled water circuit operating at temperatures optimised for the chilled beams whilst minimising the risks associated with condensation within the device.

The active chilled beams shall be installed in series with radiant panels, where required, on the dedicated heating circuit serving the areas with 4-pipe chilled beams.

The Sub-contractor shall allow for supplying samples and constructing mock-ups for comment. This shall include ceiling mock-ups for the chilled beams.

The Sub-contractor shall allow for witness testing the devices, in a mock up single bedroom, in the manufacturer's thermal laboratories to ensure the comfort condition requirements can be achieved. This shall include simulation loads in the space and readings from hot wire anemometers and turbulence probes at pre-determined points within the space.

CFD calculations will not be accepted in isolation as method of proof for meeting the comfort requirements.

The comfort conditions shall be tested, as above, in accordance with BS EN ISO 7730 and shall prove that a category A room can be provided.

All emitters shall have smooth easy clean surfaces with no sharp edges or dirt collecting gaps.

All emitters shall be suitable for hospital application.

Access doors and hatches shall be provided for service and maintenance purposes.

All elements of the work shall be in accordance with the requirements of current legislation, regulations and industry standards.

The installation shall also comply with all relevant Code of Practice and British standards.

210 DESIGN

- System designs to be completed: Active chilled beam systems.
- Testing standards:
 - Capacity: To BS EN 14240.
 - Comfort: To BS EN ISO 7730.
- Proposals: Submit drawings, technical information, calculations and manufacturer's literature.

PRODUCTS

The chilled beams shall be installed as per drawings, specification and manufactures instructions.

The chilled beams shall have low velocity air distribution into the space to prevent draughts and noise.

Beams shall come complete with the manufacturer's connection terminal card, valves, actuator, condensation sensor and terminal box with input and output terminals, *and volume control damper on the primary air inlet.*

310 CLIMATIC BEAMS, ACTIVE

The active chilled beam shall have a galvanised steel case with combined cooling and supply air unit for flush installation within suspended ceiling.

The cooling capacities of the chilled beams shall be controlled by regulating the water flow rate according to the control signal from the room temperature controller.

Heating and chilled water connections shall be provided with 2-port control valves. Local pipework shall also include flexible connections, self-sealing pressure tapings, air vents and drains.

An integral anti-condensation sensor shall be provided on the chilled water flow pipe to close the control valve in the event of the chilled water temperature falling below 15°C.

For more details of the control of the active chilled beams the Sub-contractor shall refer to the relevant BMS controls specification.

The main pipelines of the cooling and heating water circuits should be installed above the beam in order to enable venting of the pipework.

Each beam shall have a measurement tap for static pressure measurement, to enable measurement of the supply airflow rate.

Chilled beams shall be of the enclosed hygienic type, with the beam casing sized to integrate with a standard T shaped grid. The return air grille panel shall be removable from within the treated space with all internal components capable of being cleaned without further dismantling. The performance criteria for the active chilled beams is provided below:

Chilled Beam Reference		CB/W1/L1	CB/W1/L2	CB/W1/L3	CB/W1/L4	CB/W1/L5	CB/W1/L6
Nominal Size		600 x 600	600 x 1200	600 x 1200	600 x 1200	600 x 1200	600 x 1200
Heating	Water LVT HTG F/R	60/50	60/50	60/50	60/50	60/50	60/50
	Output (Water Only)	1000	1480	1000	1480	1570	1570
	Design Water Flowrate F/R	0.024	0.036	0.024	0.036	0.037	0.037
	Maximum Coil ΔP	10	10	10	10	10	10
	Primary Supply Air Temperature	16	16	16	16	16	16
	Room Design Temperature	22	22	22	22	22	22
Cooling	Water CB CHW F/R	15/18	15/18	15/18	15/18	15/18	15/18
	Output (Water Only)	430	430	780	780	480	900
	Design Water Flowrate F/R	0.034	0.034	0.063	0.063	0.038	0.071
	Maximum Coil ΔP	10	10	10	10	10	10
	Primary Supply Air Temperature	18	18	18	18	18	18
	Room Design Temperature	26	26	26	26	26	26
Air	Primary Airflow	40	40	40	40	40	40
	Maximum Total Static Pressure	80	80	80	80	100	100

The beam casing shall have a stove enamelled finish in white to RAL 9010.

- Type: Enclosed hygienic type.
- Manufacturer: The Sub-contractor is to provide technical submissions for review.
- Flexible connectors: Provide connectors to allow each panel to be lowered for inspection and maintenance.
- Casing:
 - Material: galvanised steel case.
 - Material thickness: Submit proposals.
 - Surface treatment: hygienic with no burrs.
 - Perforations: Standard Manufacturer's plate.

EXECUTION

The Sub-contractor shall ensure all works carried out shall be done in a safe manner and comply with Health and Safety Regulations. This shall include clean and tidy working and working in confined spaces. The Sub-contractor shall protect the chilled beams from damage or interference during the works

620 SETTING OUT

- General: Co-ordinate with ceiling system to maintain the beams and ceiling panels accurately, continuous and even.
- Alignment: Straight and parallel to walls or setting out lines.
- Infill and access units, integrated services: Fit correctly and align.
- Support: Manufacturer's standard. The Sub-contractor shall liaise with the Architect in locating the grilles and diffusers on the architectural reflected ceiling plans as necessary.

630 INSTALLING CLIMATIC BEAMS

- General: Position accurately, parallel to outside wall.
- Alignment: Level in relation to ceiling.
- Mounting: Recessed, Any imperfect Beams scratched or damaged surfaces, or fixing screws having damaged heads or scratched plating, shall be rejected and must be replaced free of charge with satisfactory work before the contract shall be taken over as completed. Beams shall be installed level with the ceiling line and square with adjacent ceiling tiles. Where direct fixing to the ceiling is not inherent to the ceiling layout, the Sub- Contractor shall ensure that adequate concealed supports are provided to ensure that beams are installed at the correct level and square with the surrounding ceiling and adjacent luminaires. All beams shall be supplied in a fully finished condition and shall be provided with protective covering during building operations, and subsequently removed by the Sub-contractor.
- Support: Provide chains to take the weight of the beams when lowered for inspection.

U10 VENTILATION SYSTEMS

ALL AIR SYSTEMS

These shall be low velocity systems with air being distributed throughout the building in galvanised sheet steel ductwork via ceiling voids and riser duct spaces terminating in ceiling or wall diffusers as appropriate.

On full fresh air systems, heat recovery devices shall be provided, to exchange heat between exhausted extract air and incoming fresh air wherever significant energy savings can be achieved.

Generally, temperature control shall be by means of room or duct-mounted sensors which shall operate, via the automatic control system software the control valves on the hot water and chilled water to the heating and cooling coils respectively (refer to BMS specification for further details).

Areas shall be controlled in zones or as individual rooms as necessary to achieve the conditions required by the ADB Sheets.

Space shall be provided in all units for future incorporation of activated carbon filters to control odours entering the ventilating systems. Space shall also be included to upgrade the pre-filter from panel filters to bag filters.

Supply plants shall incorporate panel type coarse pre-filters followed by high efficiency bag filters. Absolute HEPA (high efficiency particulate air) terminal filters shall be provided only for 'ultra clean' areas such as UCV Theatres, Pharmacy Aseptic Suite and as a future allowance for isolation rooms. Some isolation rooms incorporate HEPA filters on the extract system.

Full humidity control, including humidification and dehumidification, shall be provided only in critical air-conditioned clinical areas such as the Pharmacy Aseptic Suite or wherever close control of humidity is required for the successful operation of sensitive equipment, e.g. computers, as advised by the ADB Sheets. Space shall be included within Operating Theatre air handling units for the provision of humidification in the future. Since the anticipated requirement for humidification is limited this shall be provided by electric steam injection humidifiers.

Air pressure regimes for theatre suites shall be designed in accordance with the guidance provided in SHTM 03-1 employing wall mounted pressure stabilisers.

Air volumes have been established by consideration of heat gains or losses and also the air change rate necessary for comfort and safety as appropriate for the activity carried out in each area. Relative air pressures between rooms shall be maintained to suit the activity concerned, by design of the supply and extract air volumes, and use of pressure relief equipment where necessary to prevent cross infection or transfer of unpleasant odours between areas, as required by the ADB sheets.

Heat recovery shall be provided between the supply and extract systems. The hospital ventilation systems shall be in accordance with SHTM 03-01 Ventilation in health care premises, DW 144 and DW 143.

The ventilation system including all AHU's, fan's, diffusers, dampers and grilles shall meet the design noise and vibration criteria.

The ventilation and cooling system shall be zoned with each air handling system being served by packaged air-handling units containing all components necessary (e.g. fans, coils, filters, etc.) to provide the correct environmental control of those spaces/rooms served.

The philosophy of the system is to provide energy efficient operation with areas of the hospital operating on a similar time and clinical nature being served from the same system, and to maintain a sensible level of availability, such that in the event of plant breakdown or maintenance, limited areas of ventilation are lost. Air handling plants shall have availability reinforced by the provision of duplicate motors or fans, which shall automatically changeover to maintain the ventilation requirements.

The Sub-contractor shall take care in finally co-ordinating the ductwork routes to avoid potential causes of high pressure drop that will have a detrimental effect on ultimate fan performance.

All ventilation controls must be capable of being fully interrogated by the building management system through the independent network protocol.

WARDS

The ventilation systems serving ward areas shall provide treated air to internal spaces, clinical spaces and make-up air for sanitary accommodation.

Make up air for en suite WC accommodation shall be introduced directly into the associated bedroom and via active chilled beam units to maintain the required space temperatures.

The beams shall be complete with dedicated controls enabling temperatures to be varied within each treated space. The controls shall comprise local digital room mounted temperature sensor/controller operating 2-port electrically operated valves in response to user inputs to raise or lower the room temperatures.

Air shall be extracted from spaces by either the clean or dirty extract systems as appropriate. Heat recovery shall be provided between the supply and extract systems. The type of recovery system employed shall depend on the area being served. Refer to system drawings and schedules for details.

The ward tower shall use different facades of the building for intake and exhaust air. The podium plantrooms shall use roof turrets for extract air and vertical wall louvres for supply air. This strategy should avoid short circuiting or contamination of the supply air and also meet the BREEAM requirement for separation. The Sub-contractor shall exercise caution when locating any other extracts or gas scavenging exhaust to ensure the supply intakes are not contaminated.

The tower shall be zoned to match the different load profiles with each finger being served by three AHU's. e.g. the external facade with higher solar gains, the central zone and the facade with lower solar gains. Each AHU shall serve four floors in this configuration. The centre circulation are shall have two zones each served by a different AHU, again each

AHU shall serve four floors.

ISOLATION ROOMS

Each lobbied isolation room shall be provided with its own dedicated ventilation system in line with SHBN 04.

Each system ventilation plant shall filter, heat and cool the air and supply it to the room lobby at the required temperature, as dictated by a sensor in the bedroom.

Air shall be transferred to the room via a wall mounted pressure stabiliser and then extracted from the suite via the bedroom and en suite WC, and ducted by fire-clad ductwork to a dedicated extract fan in the plantroom.

Each extract fan unit shall comprise of an isolation damper and a centrifugal cased extract fan, with the motor located out of the air stream, and the exhaust duct shall discharge 3.0 metres above roof level. In the Level 2 plantroom serving the Critical Care Ward it is not possible to achieve a safe discharge height of 3.0 metres above roof level. In this case the extract air shall be HEPA filtered through 'safe change' filter units in the plantroom before being discharged to atmosphere with all other ventilation exhausts.

Due to the small size of the plants, heat recovery is not considered viable and shall therefore not be provided.

Isolation rooms supply air terminals shall be capable of having terminal HEPA filters fitted at some future date. The air handling unit fan shall be capable of overcoming the additional resistance imposed by the HEPA filter by a simple speed change on the motor inverter.

OUTPATIENT TYPE DEPARTMENTS

The ventilation systems serving outpatient areas shall provide heated air to internal spaces, clinical spaces and make-up air for sanitary accommodation.

Active chilled beams shall generally be provided to individual spaces to provide independent control of heating and cooling requirements.

Air shall be extracted by clean and dirty extract systems.

Heat recovery shall be provided between the supply and extract systems.

OPERATING THEATRES

Each operating theatre shall be provided with a dedicated ventilation system.

Each system ventilation plant shall filter, heat and cool the air and supply it to the suite of rooms, and arranged to allow individual temperature set point adjustment and indicated on the associated surgeon's theatre panel (refer to BMS specification).

The pressure regimes between the spaces in each theatre suite shall be maintained by a combination of supply and extract rates to each space, and pressure stabilisers located in the walls.

Heat recovery shall be provided between the supply and extract systems. Out of hours

setback shall be provided by reducing the air volumes and temperature set points.

In theatres with a requirement for Ultra Clean Ventilation (UCV), a specialist shall be employed to undertake the provision of the UCV canopy in accordance with SHTM 03-1.

Ancillary areas associated with the Operating Theatre department shall be served from a dedicated plant.

CRITICAL CARE DEPARTMENTS

Critical care departments such as ITU/HDU shall be provided with dedicated ventilation systems.

The supply air ventilation plant shall heat and cool the air as required by the control system to provide the correct condition in the various rooms/zones.

Final temperature control to the spaces shall be achieved by terminal reheaters controlled from user adjustable sensors within each space. Heater batteries shall be located wherever possible in plant areas, but where heaters can only be provided in the ceiling void of the occupied space they shall be located away from patient occupied spaces, i.e. bed spaces.

Heat recovery shall be provided between the supply and extract systems.

COMFORT COOLED AREAS

Departments where space temperature control is required, such as the Emergency Centre, Diagnostic Imaging, etc. cooling shall be provided by treated air to clinical spaces and spaces with high equipment gains.

The department shall be arranged in a number of zones to suit the control requirements, varying heat gains and use of the spaces.

Particular areas that have high-density heat gains shall be provided with terminal cooling in the form of fan coil units to achieve the required space conditions.

The supply air ventilation plant shall heat or cool the air as required by the control system to provide the correct condition in the various rooms/zones.

All AHU's and fans shall be suitable for hospital application refer to drawings and schedules for further details.

SAFETY CABINET EXTRACT SYSTEMS

The Pharmacy shall be served by separate extract systems serving the general areas whilst extracts from safety cabinets shall be handled by individual contaminated extract systems.

The design of the general extract system shall be co-ordinated with the associated supply system and contaminated extracts to maintain suitable pressure levels and ensure the Clean Room requirements of the Aseptic Suite are maintained.

The Aseptic suite is a "clean space" and as such shall be installed and commissioned as per SHTM 03-01 AND HBN 14-01. equipment shall be fully commissioned to validate their

function and achievement of performance.

QUENCH PIPES

The Quench pipes serving the MRI machines shall be installed by the sub-contractor in accordance with a design and specification produced by the MRI supplier/installer. The route of the pipes shall be as shown on the drawings and they shall be insulated and terminate in accordance with the recommendations given by the MRI supplier/installer. The Quench pipes are required to be continuous and therefore the pipe structure and insulation shall maintain the required 2 hour fire integrity.

130 MECHANICAL SUPPLY VENTILATION SYSTEM

Supply air from central air handling plant shall be delivered through the ductwork systems to the areas served, and discharged via ceiling mounted diffusers.

Supply and extract air handling plants shall be of a packaged construction with a double skin casing complete with thermal/acoustic insulation material between the two skins. Units shall house filters, coils, fans and motorised inlet dampers, etc. Heat recovery devices and humidifiers shall also be incorporated where required. External fan motors shall be provided to all units with some unit types having twin motors.

All AHU's and fans shall be suitable for hospital application. Refer to drawings and schedules for further details.

- Location of plant: Various locations throughout the building.
- Type of system: Multizone, constant volume.
- External air intake terminals: Architectural louvres.
- Air filters: In air handling units, as section U81.
 - Accessories: As schedule.
- Heat recovery: In air handling units, as section U81/U85.
- Air handling units: As section U81 and schedules.
 - Fabrication: Construction, as section U81.
- Supply fans: As schedule.
- Acoustic treatment: Rectangular silencer, as section U87.
- Air ductwork and ancillaries: Ductwork, Fire rated and smoke extract ductwork and fittings, as section U80.
 - Accessories: Dampers, fire and smoke, metal ductwork, as section U80.
- Thermal insulation on supply air ductwork: As section Y30.
- Vibration isolation mountings: Spring isolators, as section Y31.
- Reheat batteries: As schedules and drawings.
- Room supply air terminal devices: Chilled beams, grilles and diffusers as specified.
- Controls: All ventilation controls must be capable of being fully interrogated by the building management system through the independent network protocol.
- Completion:
 - Identification of ductwork and equipment: As section Y32.
 - Testing and commissioning:
 - Ductwork pressure testing, as section U80;
 - Air distribution system commissioning, as section Y50; and
 - Performance testing, as section Y50.

140 MECHANICAL EXTRACT VENTILATION SYSTEM

Extract air from the area concerned shall be drawn through a ductwork system to extract fans in the roof plantrooms for discharge to atmosphere, or returned to the air handling plant for recirculation.

- Room extract air terminal devices: As drawings.
- Air ductwork and ancillaries: Fire rated and smoke extract ductwork and fittings, as section U80 and Smoke extract ductwork, as section U80:
 - Accessories: Dampers, fire and smoke, metal ductwork, as section U80 and Flexible ductwork, as section U80.
- Thermal insulation on extract air ductwork: As specified.
- Vibration isolation mountings: Spring isolators, as section Y31.
- Heat recovery: Plate recuperator, as section U85 or thermal wheel, as section U85 depending on AHU type.
- Acoustic treatment: Rectangular silencer, as section U87.
- Extract fans: The extract fan shall have twin motors depending of fan type.
- External exhaust air terminals: Architectural louvres
- Controls: All ventilation controls must be capable of being fully interrogated by the building management system through the independent network protocol.
- Completion:
 - Identification of ductwork and equipment: As section Y32.
 - Testing and commissioning:
 - Ductwork pressure testing, as section U80;
 - Air distribution system commissioning, as section Y50; and
 - Performance testing, as section Y50.

150 TOILET EXTRACT VENTILATION SYSTEM

Potentially contaminated dirty air extract systems shall be discharged at, or above, roof level.

Dirty extract shall be provided to extract air from toilets, bathrooms, cleaners' rooms and dirty utility areas. Extract plants shall either form part of the general area air handling unit or be separate extract fan units.

Air shall be extracted via grilles in the individual rooms and ducted by galvanised sheet steel ductwork similar to that provided for the general supply and extract systems to extract fans in the plantrooms. Make up air shall be via the main ventilation system.

Separate dirty extract units shall be manufactured heavy gauge aluzinc corrosion resistant steel. The general construction is to Class A leakage.

The fan unit shall be supplied complete with all manufacture control accessories to be fully integrated into the BMS.

The fan unit shall be provided with an integrated commissioning/speed control to accurately commission the system. The commissioning set up facility directly controls the integrated speed control/frequency inverter.

Heat recovery shall be used for the larger dirty extract systems.

Where toilets or bathrooms are in isolated positions, not convenient to central ducted systems, small units operated by light switch control shall be used

- Room extract air terminal devices: Air transfer grilles and diffusers, as specification.
- Air ductwork and ancillaries: Sheet metal ductwork and fittings, circular, as section U80 and Sheet metal ductwork and fittings, rectangular, as section U80:
 - Accessories: Dampers, fire and smoke, metal ductwork, as section U80 and Flexible ductwork, as section U80.
- Thermal insulation on extract air ductwork: Not required
- Vibration isolation mountings: Spring isolators, as section Y31.
- Acoustic treatment: Circular silencer, as section U87 and Rectangular silencer, as section U87.
- Extract fans: Twin Toilet extract fans run and standby, as section U82.
- External exhaust air terminals: Architectural louvres.
- Controls: All ventilation controls must be capable of being fully interrogated by the building management system through the independent network protocol.
- Completion:
 - Identification of ductwork and equipment: As section Y32.
 - Testing and commissioning:
 - Ductwork pressure testing, as section U80;
 - Air distribution system commissioning, as section Y50; and
 - Performance testing, as section Y50.

160 KITCHEN EXTRACT VENTILATION SYSTEM

Ventilation to the central catering areas shall be provided to deal with the requirements on the cooking equipment to reduce odours and limit temperatures within the space.

Contaminated air extract systems shall be discharged at, or above, the tower roof level at high velocity as appropriate.

Ventilation make-up air shall be provided to balance the extracted air.

There shall no recovery from kitchen hood extract due to the difficulties with grease laden air.

The kitchen canopies shall be supplied and installed by the kitchen specialist and do not form part of these works. The Sub-contractor shall liaise with the kitchen specialist, so as to agree requirements. All the main kitchen extract hoods to be the capture/entrainment type. This type of canopy entrains the contaminant air by supplying fresh air over the kitchen island. This shall reduce extract air flow rates and hence save energy. The hoods and supply air shall also have a set back position when the kitchen is not in use. This shall reduce air flows when the kitchen is not in use and energy consumption

- Air ductwork and ancillaries: Fire rated and smoke extract ductwork and fittings, as section U80. All kitchen extract systems to DW172:
 - Accessories: All kitchen hood extract ductwork to be fire rated.
- Thermal insulation on extract air ductwork: Not required.
- Vibration isolation mountings: Spring isolators, as section Y31.
- Acoustic treatment: Sub-contractor's specialist to examine.
- Extract fans: Centrifugal belt driven, as section U82.
- Completion:

- Identification of ductwork and equipment: As section Y32.
- Testing and commissioning:
 - Ductwork pressure testing, as section U80;
 - Air distribution system commissioning, as section Y50; and
 - Performance testing, as section Y50.

EXECUTION

The Sub-contractor shall ensure all works shall be done in a safe manner and comply with Health and Safety Regulations. This shall include clean and tidy working and working in confined spaces.

All supply and extract ventilation systems should be clearly labelled. The label should identify both the AHU and the area that it serves. The lettering should be at least 50 mm high and be mounted in an easily visible place near the fan of the unit. Any sub-systems and the principal branch ducts should be similarly labelled. The direction of air flow should be clearly marked on all main and branch ducts.

630 INSTALLING DUCTWORK ON AIR HANDLING UNITS

- Air discharge: Connect ductwork to allow air to straighten as it leaves the air handling unit.

U41 FAN COIL UNITS

310 FAN COIL UNITS

Fan coil units shall be complete with dedicated controls enabling temperatures to be varied within each treated space. The units shall, where applicable, include heating. The controls shall comprise local room mounted temperature sensor/controller operating 2-port electrically operated valves in response to user inputs to raise or lower the room temperatures.

All Fan coil unit motors shall be fitted with built in Thermal overload protection.

- Performance: To BS 4856.
- Manufacturer: Sub-contractor's choice
 - Product reference: Sub-contractor to provide technical proposals.
- The Sub-contractor shall examine all layout drawings, schematics and schedules, in order to ascertain duties and required temperatures.
- Fan speed: Low.
- Fan motors: EC type with a Specific Fan Power less than 0.8 watts per litre/second
- Noise levels: As fan coil schedule.
- Electrical supply type: As fan coil schedule.
- Casings: As manufacturer's standard for application.
- Mounting: As manufacturer's standard for application.
- Finish: As manufacturer's standard for application.
- Ductwork connections: Sub-contractor to provide proposals.
- Access: Provide access to filter, fan and motor, valves and controls.
- Drip tray:
 - Position: Under coil, and under control valve where fitted.
 - Material: Corrosion resistant.
 - Condensation: Insulate external faces to prevent.
- Controls: All ventilation controls must be capable of being fully interrogated by the building management system through the independent network protocol.
- Accessories: As Fan coil schedule.

EXECUTION

The Sub-contractor shall ensure all works carried out shall be done in a safe manner and comply with Health and Safety Regulations. This shall include clean and tidy working and working in confined spaces.

610 FAN COIL UNIT DRAIN LINE

- Drain connections: Connect drain line flush with bottom of drip tray.
- Drain line: To discharge via a suitable dry type trap.

U60 LOCAL AND ROOM AIR CONDITIONING SYSTEMS

GENERAL

Generally ventilation and comfort cooling shall be from central systems. Where this is not possible because of the remoteness of the area from the main plant, the particular use of the space, or high cooling loads, local systems shall be used. The Sub-contractor shall ensure that these systems are installed to the same high standard as the main system.

PRODUCTS

All elements of the work shall be in accordance with the requirements of current legislation, regulations and industry standards. The installation shall also comply with relevant British Standards. The Sub-contractor shall provide working drawings for the installation and issue them for comment before work commences.

340 COMPUTER ROOM AIR CONDITIONING UNITS (CRAC)

The two main server room air-conditioning systems shall be feed from the main chilled water system. Computer rooms shall each be provided with independent systems via dedicated secondary chilled water circuits having their own plate heat exchangers and circulating pumps.

CRACs shall be floor standing 'downflow' type and CRACs must be capable of being fully interrogated by the building management system through the independent network protocol.

To comply with these directives appropriate national & harmonised standards have been applied. These are listed on the Declaration of Conformity, supplied with each product.

Unit cabinets shall be manufactured from galvanised sheet steel coated with epoxy baked powder paint to provide a durable finish. Internal strength and rigidity shall be provided by a welded space frame constructed of channel profile folded steel. Cabinets shall be lined internally with fire resistant 20mm foam (UL94 V0) for thermal and acoustic insulation. Cabinets shall meet the Hospital acoustic and vibration requirements. The cabinet doors are full height, hinged and key lock secured. Door arrangement shall allow flexible door opening/removal for improved access. Doors shall have rubberised door seals reduce sound breakout and eradicate leakage.

The units shall have large surface area coil(s) to optimise airflow and heat transfer, manufactured from refrigeration quality copper tubes with mechanically bonded aluminium fins.

Fins shall be coated with a non-stick acrylic film to provide additional corrosion protection and efficient surface water removal for improved performance.

Coil headers shall be circuited to ensure low water pressure drops. The cooling coils shall be mounted over a full width stainless steel condensate tray. Chilled water flow shall be via a factory fitted 3 port modulating control valve.

All coils shall be Factory pressure tested to 20Bar.

Fans shall be backward curved impellers, direct drive centrifugal fan assemblies with integral rotor mounted motor which is statically and dynamically balanced for quiet operation. Designed for high corrosion resistance, the impellers are laser welded aluminium with galvanised rotor and die cast aluminium EC power module. An inbuilt EC fan control module shall allow the fan to modulate from 15-100%.

Filters shall be 97mm pleated disposable panel filters in a rigid frame. Conform to BS EN 779-G4.

Access and removal from unit front. An adjustable diaphragm pressure switch fitted across the filter assembly shall monitor pressure drop which shall initiate a filter dirty alarm.

The control panel shall have fan motor contactors and overloads, transformer, sub circuit protection, volt free contacts, mains and inter-connecting terminals. The panel shall be fitted within the cabinet and be hinged for easy access to other components within the unit. The electrical control panels shall be wired to the latest European standards and codes of practice.

To ensure complete unit isolation of the electrical panel during adjustment and maintenance a door interlocking isolator is provided as standard.

Units shall be fitted with the microprocessor controller which shall have a real time clock and a communication port plus networking and Bac Net BMS connections. A backlit LCD door mounted display keypad assembly shall be fitted to view the unit status and allow operator adjustment.

The condensate pump shall have a reservoir with a capacity of 5 l/m at a head of 10.8m.

Leak detection tape suitable for sensing water droplets shall be supplied loose for remote mounting on site.

- Sub-contractor to provide technical proposals.
- Arrangement: Vertical.
- Casing: Steel frame with acoustically lined steel panels.
- Finish: Manufacturer's standard.
 - Colour: Manufacturer's standard.
- Controls: All controls must be capable of being fully interrogated by the building management system through the independent network protocol.

Each server room shall be provided with the following:

- Room sensible cooling capacity 200 kW
- Number of units (N+1) 5 No.
- Sensible cooling capacity per unit 50 kW
- Sensible Heat Ratio 1.0
- Chilled water temperatures at unit Flow 8°C
Return 14°C
- Chilled water flow rate per unit 1.94 litres/second
- Maximum coil/valve pressure drop 60 kPa
- Inlet air design conditions 22°C 50% RH
- Nominal air flow per unit 3.75 m³/s

EXECUTION

The Sub-contractor shall ensure all works carried out shall be done in a safe manner and comply with Health and Safety Regulations. This shall include clean and tidy working and working in confined spaces.

U80 AIR DUCTWORK AND ANCILLARIES

During installation the ductwork shall be installed to a PDI (Protection, Delivery & Installation) as defined in the HVCA (2005) TR/19 – Guide to good practice: internal cleanliness of ventilation systems'.

A Specialist Cleaning Operation shall be performed on all ductwork systems installed serving Clinical Areas, in accordance with the guidelines of Section 9 – Verification of Cleanliness, HVCA TR/19.

The cleanliness of the ductwork installation shall be confirmed and documented by means of the post clean verification test procedure outlined in Section 9.5 of HVCA (2005 TR/19).

300 CLASSIFICATION

Ductwork shall be classified as described in Table 1 of DW/144, as follows:-

- Plantroom and main riser ductwork: Class B
- Distribution ductwork at each floor Class: A

The ductwork sub-contractor shall clearly indicate on the manufacturing and installation drawings the classification of the ductwork proposed.

All ductwork shall meet the leakage criteria given in the Building Regulations Section 6 which requires it to meet the requirements of HVCA DW/143.

10%, chosen at random, of Class B ductwork shall be selected by the Contractor for testing.

Ductwork branch connections shall be shoe type as fig 106 in DW144, spigot type branches shall not be acceptable.

The Sub-contractor shall ensure that sufficient dampers are provided to regulate and balance the system. Dampers on grilles or diffusers shall be used only for balancing of external air distribution devices in a common branch. All dampers shall be sufficiently rigid to prevent vibration within the systems, when absorbing the additional available pressure of the system.

PRODUCTS

A specialist ductwork Sub-contractor shall be employed by the Sub-contractor to fabricate install and test a range of ductwork that shall be used for general ventilation, air conditioning or comfort cooling.

305 DAMPERS, FIRE AND SMOKE, METAL DUCTWORK

The ductwork system shall be provided with fire dampers in locations corresponding to the appropriate fire separation barriers. Actuation of the dampers shall be in accordance with SHTM81 Fire Code, and the Fire Consultants Strategy Report, subject to the separation performance of the barrier.

Where actuation of the damper is via the fire alarm system the damper shall be motorised to facilitate re-opening after testing of the fire alarm system. Dampers utilising fusible link operation only shall be provided with local mechanical indicator on the side of the fire damper. Dampers with motorised operation shall be monitored via a separate electronic remote monitoring system.

Fire dampers MUST be fitted with the correct installation frame and supports.

Fire rated ductwork shall be utilised where the use of fire dampers is inappropriate.

The smoke damper control panel must be capable of being fully interrogated by the building management system through the independent network protocol.

Smoke control dampers shall be provided in the positions as indicated on the drawings and shall be suitable for mounting in the horizontal or vertical plane. They shall be certified by the manufacturer to have been tested to the temperature time curve of BS ISO 10294, for a period of 4 hours with a classification of ES 240 in the fully closed position with power off.

Smoke control dampers shall have factory fitted installation frames to HVCA 10.1.83 specification and the sub-contractor shall allow for all additional framing, supports and bracing securing the damper to the structures, to the satisfaction of the Building Control Officer.

All smoke control dampers shall be supplied with a factory fitted actuator, complete with integral micro switches and controlled mechanical fail safe operation of not more than 20 seconds.

The totally enclosed precise movement with British Standard 5588: Part 9999: 1999 should be held in the open position by means of a thermally actuated device set to operate at approximately 74 °C. Automatic smoke and fire control dampers are fire rated dampers as they are held in the reset (Open) position by a thermally actuated device.

The totally enclosed precise movement opposed blade drive shall be positioned out of airstream for protection against damage, be hard wearing and free running.

The control mode/damper connection shall be by means of the drive interface mechanism, which shall be totally independent of the ductwork.

Automatic smoke release dampers with their appropriate control modes shall have spring fail-safe open operation.

The Sub-contractor shall be responsible for allocating a unique reference number to each damper per system and produce a schedule for the purposes of carrying out the inspection and testing of all installed smoke/fire dampers. Upon completion of the tests, the certificates, with the schedule must be issued confirming that all dampers have been inspected and function correctly in accordance with the manufacturer's data sheets. The ductwork Sub-contractor is to allow for subsequent demonstration of all fire/smoke dampers to a witnessing party. Access door requirements as DW144 Appendix M require unique numbers to be identified on the fire damper and also on installation / record drawings, damper control graphics and within a schedule to be included in the O& M instructions.

The Sub-contractor shall be responsible for ensuring the mechanical inspection and testing of all smoke/fire dampers installed on the contract is carried out with the smoke damper control specialist testing and in attendance same time. Upon completion of the tests, the certificates must be issued for confirming that all the dampers have been inspected and that they function correctly in accordance with the manufacturer's data sheets.

The dampers shall comply to Class A and B of Eurovent Document 2/2 and Test Procedures for Classes A, B and C of HVCA Ductwork Specification DW144.

305A DAMPERS, FIRE AND SMOKE, METAL DUCTWORK

The slam shut curtain fire dampers shall have a stainless steel folding curtain having unbroken movable joints, stainless steel constant tension closure springs for positive closure and stainless steel peripheral gasketing.

The self resettable, latching removable release mechanism cassette, shall ensure the closure of the stainless steel curtain under full fire conditions. The housing shall be galvanised steel fully welded spigotted type casing suitable for square, rectangular, circular or flat oval connections.

The spigotted casing with continuously welded corners and spigot connections makes these dampers suitable for inclusion into air distribution systems to the test methods of Eurovent Class A, B & C and HVCA Ductwork specification DW144.

- Standard: To BS EN 1366-2.
- Type: Multi-blade.
- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Material: Stainless steel.
- Accessories: External visual indication of fire damper blade position.
- Fusible links fusing temperature: 72°C.

310 DAMPERS, NON-RETURN

Non return dampers shall be installed as shown on the drawings. They shall automatically shut off individual sections of an air conditioning system.

The damper shall be selected for the type of system (constant or variable volume).

- Standard: To BS EN 1751.
- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Leakage through closed blades: Class 0.
- Casing leakage: Sub-contractor to submit proposals.
- Pressure: Sub-contractor to submit proposals.
- Material: Galvanized sheet steel frame and aluminium blades.

330 DAMPERS, SHUT OFF

Shut of dampers shall be suitable for air conditioning and ventilation systems requiring air control and low closed blade leakage characteristics. For standard low/medium pressure and velocity systems.

Air control and system balancing shut-off dampers shall comprising of stainless steel aerodynamic blades with synthetic trailing edge blade seals, synthetic blade end bearings and stainless steel top and side spring tempered flexible gasketing. Dampers to have a maximum closed blade leakage of 27 l/s at 1000 Pa when measured on a 1000mm wide x 1000mm high damper. Housed in a galvanised mild steel frame having integral peripheral flanges.

- Standard: To BS EN 1751.
- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Leakage through closed blades: Sub-contractor to submit proposals.
- Casing leakage: Sub-contractor to submit proposals.
- Pressure: Sub-contractor to submit proposals.
- Setting: Sub-contractor to submit proposals.
- Material: Galvanized sheet steel.
- Control method: Electric and electronic.

340 FLEXIBLE DUCTWORK

Flexible ductwork shall not be used in runs that are more than 1.0m. Fixed ductwork shall terminate not less than 450mm from terminal equipment. Actual lengths of flexible ductwork when fully extended shall not exceed 125% of the connection distance.

Where the flexible ductwork is to be insulated, this shall be factory applied of a type approved for the application and to the thermal conductivity equivalent to the adjacent thermal insulation, and shall be Class O fire rated.

- Standard: To HVCA DW/144.
- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Material: As specification U10.

370 *PRESSURE STABILISERS*

Pressure control flaps/pressure stabilisers are to be installed as shown on drawings. The flap/stabiliser shall accurately control the differential air pressure between adjacent rooms, and the blades close fully as soon as the pressure differential drops below the required level. This diverts the airflow to pass through an open door forcing back airborne contamination.

The damper shall come with a Standard Finish: RAL9010 powder coated white with antimicrobial protection as standard.

Bearings shall be stainless steel ball roller type sealed for life ball bearings. Pressure Control Range shall be 3 - 50 Pa with a setting accuracy of +/- 1 Pa. Where required the

flap/pressure stabilisers shall come complete with fire/fire smoke damper.

The fire/smoke damper shall be standard smoke/fire damper integrity tested to BS EN 1366 for 245 minutes - ES classification (ES245). The fire/smoke damper shall be enclosed in a case with the flap/stabiliser as one unit and the entire case shall be powder coated white with antimicrobial protection as standard. The fire damper must be compatible and be capable of being controlled by the fire damper control panel/system.

- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Material: Stainless steel flap and adjustable balance weight assembly.
- Wall mounting casings material: Sub-contractor to submit proposals.
- Control pressure of balance weight: Sub-contractor to submit proposals.

380 ACCESS DOORS

An access panel shall be provided adjacent to all items of in-line equipment that require either regular servicing or intermittent access.

Access doors shall not generally be less than 450 mm long by the full width of the duct on sizes up to 450 mm wide. For ductwork sizes up to 600 mm wide, access door shall not be less than 450 mm x 450mm clear opening. Ductwork sizes for 600 mm-900 mm shall have not less than 600 mm x 450 mm access doors. For ducts with longest dimensions below 300 mm Level 2 access doors DW/144 Table 25 shall apply. For ductwork with sides longer than 900mm access door sizes shall be agreed with the Sub-contractor. Where man access into ductwork is possible then the supports and fixing shall be suitable to support the weight of an occupant and tools. Access doors shall be installed adjacent to all coils and batteries for inspection and cleaning.

Access and inspection opening locations shall be in accordance with Part 7 of DW/144 and suitable to comply with the requirements of TR/19 with the exception of above and the following.

All doors shall be fitted with rust-resistant quick release fasteners and those in the riser shafts shall be supplied with an approved retaining device fixed to door and frame. Access doors shall be capable of withstanding the respective system test pressures referred to in Table 1 of DW/144.

All access doors are to be pre-insulated and shall be constructed and installed in such a manner that the internal face of the duct and door is maintained when fixed. On insulated services all access doors shall be fitted with raised stools which shall be equal to the depth of the insulation. For tender purposes assume insulation thickness of 38 mm. All insulation finishes shall be extended to the neck size of the access door with the access doorframe returns exposed on the surface of the insulation finish.

Ductwork test holes shall be required to be drilled in the locations recommended in SHTM 2025/03-01 (Commissioning) and identified by the commissioning engineer. Test holes shall be drilled and located in accordance with the requirements of BSRIA Application Guide 3/89 Section C3.2 at the positions confirmed by in situ marking or marked up ductwork drawings. Each test hole to be sealed with a top hat grommet. Locations shall not be limited to those described.

Access doors, panels and covers other than those regarded as standard practice (see

DW/144) shall be marked on the manufacturers drawings issued for comment or noted below or in other sections of this specification, including type to be used.

Details of large access openings shall be agreed and shall be:-

Fitted in readily accessible locations and suitable for the purpose.

Provided to the sizes, requirements and positions recommended in DW/144 and this specification and on the drawings, utilising suitable proprietary products, which meet the relevant pressure classifications. Provided adjacent to duct mounted filters, cooling coils, fans, heating coils, humidifiers, and all dampers including hand fire and smoke dampers to facilitate easy cleaning and maintenance.

For air-conditioning (A.C) systems access doors provided for Level 3 access and for other ventilation systems Level 2 access is provided all as indicated on DW/144 Table 25.

Access doors shall be sealed, to ensure an airtight seal with a soft EDPM full-face gasket secured to the ductwork with an approved adhesive. Fire rated to match the standard of ductwork in which they are installed. Insulated in all thermally insulated ductwork to match the insulation value of the associated lagging and maintain the vapour barrier.

FABRICATION

Ductwork used for general ventilation system (including air-conditioning and comfort cooling) shall be manufactured from sheet steel and may be rectangular, circular or flat oval as indicated on the scheme design drawings. Ductwork constructed from an alternative material shall be agreed with the Contractor and clearly indicated on the scheme drawings. Ductwork, shall generally be constructed from zinc coated Steel as described in DW/144.

The specialist ductwork Sub-contractor shall be responsible for:-

Reviewing associated Architects and Structural Engineers drawings to confirm routes, availability of supports etc. Site measuring built structures to confirm suitability of routes, co-ordination (with the structure).

Provision of manufacturing/installation and builderswork drawings associated with the ductwork system.

Provision of support details and proposed locations. This shall be via manufacturing drawings and mark-ups on Architectural/Structural engineers' scheme drawings.

Co-ordination and installation of all ductwork components not directly supplied by the ductwork Sub-contractor.

Manufacture and supply of all ductwork, and associated components. Installation, air leakage testing, and component operation testing of the ductwork systems and their associated equipment. Preparation of as-fitted ductwork drawings - issued as electronic copy and hard copy at a scale of 1:50 or 1:25.

All the forgoing responsibilities shall be co-ordinated and integrated within the agreed programme of installation.

520 FIRE RATED AND SMOKE EXTRACT DUCTWORK AND FITTINGS

Where indicated on the scheme drawings or where passing through fire rated rooms/enclosures, ductwork shall be of fire rated construction equal to the room/enclosure through which it passes, in accordance with the Fire Consultant's Strategy Report and NHS Fire Code SHTM 81. The Sub-contractor shall review the fire strategy and architects drawings.

The location of the fire enclosing structures and their value (in hours) are indicated on the Architects drawings.

The ductwork shall be constructed as a complete system to provide the rated protection for stability, integrity and insulation when tested in accordance with SHTM 81 and BS. Any components within the system shall maintain the overall integrity in accordance with the test procedures.

Where ductwork services penetrate fire rated walls and cavity barriers, the penetrations shall be sealed after installation by the main contractor using a proprietary fire sleeve/sealant as manufactured by specialists.

The ductwork systems shall be fire stopped where appropriate. Where plastic ductwork is specified the ductwork Sub-contractor shall supply and fit to ductwork intumescent sleeves for the main contractor to finish too.

The ductwork shall be constructed as a complete system to provide the rated protection for stability, integrity and insulation when tested in accordance with BS476 Part 24. Any components within the system shall maintain the overall integrity in accordance with the test procedures.

All fire rated ductwork shall be constructed and installed by a specialist supplier who shall certificate the complete system to the approval of the Local Authority Building Control Officer.

The standard of fire stopping shall give greater or equal fire resistance as the construction through which the service penetrates. Where sheet steel or rolled steel section sealing flanges are required the ductwork Sub-contractor shall provide them.

Cleanliness and leak tests shall be as main ductwork section.

- Standard: To HVCA DW/144.
- Fire resistance to BS 476-24: As this specification.
 - Stability: To meet room requirements.
 - Integrity: To meet room requirements.
 - Insulation: To meet room requirements.
- Accessories:
 - Materials: Compatible with ductwork.
 - Finish: Match ductwork.

530 PLASTICS DUCTWORK AND FITTINGS, CIRCULAR (No plastic ductwork shall be used without prior written agreement of the Contractor)

- Standard: To HVCA DW/154.

- Environmental conditions for plastics ductwork: As drawings.
- Material: As drawings.
- Regulating dampers: As drawings.
- Flexible joint connections: Fit on fan inlets and outlets and at building expansion joints.
- Hangers and supports
 - Strength requirements: To BS EN 12236.
- Access openings: As required.

550 SHEET METAL DUCTWORK AND FITTINGS, CIRCULAR

Standard components shall be used wherever practical. Circular ductwork supports shall be as Figures 65 (drop rod studding only) or 66(DW/144).

- Standards: To HVCA DW/144, BS EN 1506 and BS EN 12237.
- Air leakage testing: As classification requirement.
- Special installations: Not applicable.
- Material: Suitable for system and as drawings.
- Construction: Spirally wound.
- Regulating dampers:
 - Balancing type: Suitable for system and as drawings.
 - Operation: Suitable for system.
 - Material: Suitable for system.
- Flexible joint connections: Fit on fan inlets and outlets and at building expansion joints.
- Hangers and supports
 - Strength requirements: To BS EN 12236.
- Access openings:
 - Function:
 - Inspection;
 - Cleaning; and
 - Maintenance.
 - Sizes: As DW 144 and Part U10.

560 SHEET METAL DUCTWORK AND FITTINGS, RECTANGULAR

Any duct with an aspect ratio greater than 4:1 shall be supplied with a central splitter. For all slide-on flange systems (Mezz or similar) with bolted corners, joints on all systems to be further secured with intermediary fastenings to the Manufacturer's recommendations. Only full girth stiffeners shall be used. Dimpling, self-tapping screws and piercing screws shall not be used as fasteners on ductwork. Turning vanes shall be double skinned as (DW/144) and attached to ductwork using guide rails as indicated in DW/144. Access doors are required in accordance with HVCA guide TR/19 Tables 2 and 3.

The ductwork Sub-contractor may use radius bends as Figure 29 (DW/144) as an alternative, enabling turning vanes to be omitted.

- Standards: To HVCA DW/144 and BS EN 1505.
- Air leakage testing: As classification requirement.
- Special installations: Not applicable.
- Material: Suitable for system and as drawing.
- Regulating dampers:
 - Balancing type: Suitable for system and as drawing.
 - Operation: Suitable for system.

- Material: Suitable for system.
- Flexible joint connections: Fit on fan inlets and outlets and at building expansion joints.
- Hangers and supports
 - Strength requirements: To BS EN 12236.
- Access openings:
 - Function:
 - Inspection;
 - Cleaning; and
 - Maintenance.
 - Sizes: As DW 144 and Part U10.

EXECUTION

The Sub-contractor shall ensure all works carried out shall be done in a safe manner and comply with Health and Safety Regulations. This shall include clean and tidy working and working in confined spaces.

610 GENERAL

- Cut edges on ductwork, flanges and supports: Smooth and burr free.

630 INSTALLATION OF PLASTICS DUCTWORK

- Standard: To HVCA DW/154.
 - Other requirements: Generally no plastic ductwork shall be used.
- Installing flexible joint connections: Minimize pressure drop.

640 INSTALLATION OF SHEET METAL DUCTWORK

- Standard: To HVCA DW/144.
 - Other requirements: Hangers and supports shall be generally as Table 15 of DW/144 or with manufacturer's proprietary devices with the following qualifications.
- Installing flexible joint connections: Minimize pressure drop.

650 SUPPORT OF AIR TERMINALS UNITS IN CEILING GRIDS

- Standard: To HVCA DW/144.
- Special supports: Supply and extract grille/ diffuser supports shall be as manufacturers detail.
- Position: The Sub-contractor is responsible for the co-ordination of the reflected ceiling layout.

670 DUCTWORK SUPPORT FOR VAPOUR SEAL CONTINUITY

- Method of support:

The horizontal bearers shall be steel profiled section such as Uni-strut or similar proprietary support system. The horizontal bearers shall have a galvanised finish, and plastic end-caps. A medium density Class O rubber or EDPM gasket shall be provided between the ductwork and the support bearer horizontal surface. The gasket shall not fully deform under load. The ductwork Sub-contractor shall calculate the support system

selected. Horizontal supports shall not be used as secondary supports for additional services without prior approval. Calculations shall include the additional loads imposed by the agreed additional services. Multi-tier ductwork runs shall all be supported on individual horizontal bearers with single length common support rods sized for the combined load of all ducts being supported. Multiple section drop rods shall not be accepted. Insulated ducts with vapour sealing shall be provided with a timber or composite material isolating member between ductwork and the support bearer, either horizontally (rectangular ductwork) or circumferential (circular/flat oval ductwork).

The isolating member shall be the full depth of the insulation and shall have the insulation finish/vapour seal and where applicable encasement extended without a break at least 1 duct width or diameter either side of the support channel. The isolation rubber gasket shall also be included. The ductwork Sub-contractor shall include an allowance for insulation on all faces of ductwork when setting out in horizontal and vertical planes. Supports or bearers, that interrupt or penetrate the insulation or vapour seal, shall not be accepted.

The ductwork Sub-contractor shall provide a standard sheet of support details cross referenced with the manufacturing and installation drawings. Where cantilever brackets or other special forms of support are indicated, they shall be structurally strong enough to take the load and to transfer the imposed load to the building structure. The Contractor may require design and supporting calculations for comment prior to manufacture.

690 DRAINAGE OF DUCTWORK

- Ductwork: Install to drain entrained moisture
- Joints: Lap to minimize moisture leakage.

700 TEST HOLES

- Location: In accordance with CIBSE Commissioning Code Series A and HVCA DW/144.

710 CONTROLS AND SENSING EQUIPMENT

- Install sensors and test points to suit specialist control and sensing equipment.

720 WEATHERPROOFING

- All duct work penetrations to the external shall be weathered by the main Contractor.

740 INSTALLING CONTROL EQUIPMENT

- General: Fit sensors, damper motors and other control equipment.

760 ACCESS TO DAMPERS FOR RESETTING AND MAINTENANCE

- Location: Provide access to damper mechanisms on fire dampers; smoke dampers; combined smoke and fire dampers; and volume control dampers through access doors, false ceilings etc. Where more than one fire damper is installed in a frame provide access to all fire dampers.
- Fire links: Provide access so that they can be replaced.

790 DUCTWORK CLEANLINESS & VERIFICATION

Refer to section U80 above.

915 CLEANING OF KITCHEN EXTRACT SYSTEMS

- Cleaning: In accordance with HVCA TR/19.
- Method of test: Deposit thickness test.
- Method of cleaning: As section 7 TR/19.
- Post clean verification of cleanliness report: Submit.

940 AIR LEAKAGE TESTING OF MEDIUM PRESSURE DUCTWORK

- Standard: To HVCA DW/144.
- Procedure: Carry out tests. Submit report.
- Extent: Random testing of 10% maximum of the ductwork system.
- Test pressure: To HVCA DW/144.
- Documentation: Submit calculations used to arrive at the allowable loss for the section to be tested.

950 AIR LEAKAGE TESTING OF PLANT ITEMS

- Standard: To HVCA DW/144.
- Procedure: Include in-line plant with certificate of conformity for pressure class and air leakage classification for system under test.

960 FIRE DAMPER SPARES

- Fusible links: Supply spares.
 - Quantity: 4 no full set of spares.

U81 AIR HANDLING UNITS

PRODUCTS

Packaged supply and extract air handling plants shall be provided as defined in the schedules of equipment and as indicated on the drawings, or as defined further in this specification.

The air handling unit and fan supplier shall select the internal components of the plants, such that the overall system resistance does not result in system fan power being excessive.

The Sub-contractor shall obtain from his proposed supplier calculations to demonstrate that the Building Regulation requirements for Specific Fan Power, etc are being met along with his technical submission.

All items of the AHU plant and system controls must be capable of being fully interrogated by the building management system through the independent network protocol.

310 AIR HANDLING UNITS

The supply and extract air handling plant shall in all respects comply and align with the requirements and recommendation detailed within the Health Technical Memoranda (SHTM/HTMs), in particular SHTM/HTM 2025/03-01 and 08-01, except where specifically noted within this specification.

The AHU shall be arranged so that the majority of items are under positive pressure. Any item of plant requiring a drain should be on the positive pressure side of the fan.

AHU Plants shall be of a rigid, air tight, assembly and constructed in unitary form or consist of standard modular components, assembled to ensure even airflow throughout plant with no by-passing of active components. Sealing strips shall be provided between all component parts. Factory joints shall be fully tightened and all necessary sealing strips, nuts, bolts and washers etc. being provided for site made joints. The units shall be suitable for operating against closed dampers, i.e. no flow conditions during normal and fire operation. Panels penetrated by service pipes, electrical cables etc. shall be sealed together with all joints having an air leakage integrity at design pressure which is not less than the integrity of the associated ductwork systems.

The units shall incorporate gradual change section pieces between sections to minimise pressure drops, with spacing of components to manufacturer's recommendations to ensure satisfactory operation at each stage and allow access for inspection, cleaning and maintenance. The inside surfaces shall have smooth and easy clean finishes free from structural projection. The location of fan motor, fan belts, filters etc. shall be as detailed in the schedules and on the drawings.

All modular constructed plants shall be provided with purpose made base frames. Bases shall be of sufficient height to accommodate drainage traps from dehumidifiers, humidifiers etc. All plants shall be provided with sufficient access panels/doors and viewing windows to allow maintenance and repairs to be carried out. Coils used in air-handling units shall be rated in accordance with EN 1216. On larger plants, split/multiple coils shall be used.

Construction shall be such as to withstand maximum fan static pressure without deformation and with panel deflection of not more than 1/120 of maximum panel dimension under operating conditions.

Energy recovery shall be via a plate heat exchanger or thermal wheel (fitted with a purge sector), depending on the type of unit. Cleaning access shall be required to both sides of any energy-recovery device.

Where units incorporate humidifying plant, recuperators or cooling coils, the internal surfaces of the units liable to be affected by any free water produced shall be protected by anti-corrosion paint (white) or a similar finish. Such units shall have adequate drain trays to collect water; the drain trays shall be extended, or other means of collection shall be provided to ensure the removal of any water deposited or condensed in adjacent sections.

Trays collecting cooled water shall be insulated to prevent condensation on the outer surface. All the surfaces/features shall be suitable to withstand regular cleaning with a water solution containing 5ppm chlorine, such as 316 stainless steel. Internal sloping surfaces for humidifier and cooling coil sections to fall to drain. All drains shall be provided with glass U-traps suitable to withstand twice the negative/positive pressure produced by the fan and have a screwed access for cleaning and filling as indicated in TM13 (Minimising the risk of Legionnaire's disease) and as further defined in Department of Health Guidance Notes. Certified type test performance certificates shall be issued on completion of plant testing for fans, coils, filters and electric motors etc. Fire rating type test certificates shall be provided for filters. Individual pressure testing certificates shall be provided for coils. Specific fan performance curves shall be provided and these are to relate to the unit ESP with clean filters.

All wiring from fans is to be taken through the unit casing and a 2 metre tail left for connecting to inverters supplied by the controls specialist

Viewing ports and internal illumination shall be fitted to facilitate routine inspection of the AHU. Viewing ports should be at a convenient height so that temporary ladders are not required. Internal illumination should be provided by fittings to at least IP55 rating. Fittings shall be positioned so that they provide both illumination for inspection and task lighting. All of the lights in a unit shall be operated by a single switch.

Space for the future installation of impregnated carbon filters shall be provided in all supply AHUs due to the Hospital site being in the same district as the Scottish Water sewerage works. The type of carbon filters and hence space allowance shall also be capable of dealing with intermittent smells from the helicopter landing pad. Space shall also be included for upgrading the G4 panel pre-filters to F7 grade when the carbon filters are fitted.

The AHU's manufacture shall allow for the pressure drop caused by the carbon filters and F7 pre-filter in their calculations.

- Standard: To BS EN 13053.
- Sub-contractor to provide technical submissions for review. These are to include workshop drawings.
- Construction: Double skin.

320 AIR CONTROL DAMPERS

Motorised low leakage shut off dampers shall be located immediately behind the intake and discharge of each supply and extract system respectively. They shall be of the opposed blade type, opening through a full 90° and must close automatically in the event of power failure or plant shutdown to prevent any reversal of the system airflow.

A manually operated isolating damper should be installed between the main AHU and its distribution system to enable the unit to be isolated when cleaning is in progress.

- Function: Shut off.
 - Damper position: Dampers are to be rigid, with square connections fitted with end and edge seals of a flexible material and with minimal play in linkages. The leakage on shut-off should be less than 2%.
- Damper control: Motorized.
- Type: Multi-blade damper, opposed blade.
- Material: Manufacturer's standard.
- Ancillaries Locking device and Position indicator.

330 FILTERS

Filters shall be securely housed and sealed in well-fitting frames that minimise air by pass.

Mounting frames should be designed so that the air flow pushes the filter into its housing to help minimise air bypass. Mounting frames shall be capable of being withdrawn so that the filter can be changed without having to reach into the unit.

Neither the filter media, nor any material used in the construction of the filters, should be capable of sustaining combustion

All filters sections should be provided with direct reading dial type gauges marked with clean and dirty sectors to visually show filter status.

A complete spare set of filters shall be provided at handover. Filter grades to be as schedule.

Refer to section U83.

340 HEAT RECOVERY

Heat recovery shall be provided to air handling units and be of the type as indicated on the schedules.

Refer to section U85.

350 HUMIDIFIERS

Packaged steam humidifiers shall be provided to air handling units as indicated on the schedules.

Space shall be included within Operating Theatre air handling units for the provision of humidification in the future.

Refer to section U86.

360 PREHEATERS

Duties as schedule.

Frost coils shall be plain tube without fins, where practical. Where this is not practical coils with fins at 6mm spacing shall be used.

Refer to section U84.

370 COOLING COILS

Duties as schedule.

Refer to section U84.

380 REHEATER

Duties as schedule.

Refer to Section U84.

390 FANS

Fans shall be selected to limit the total system (supply and extract fans) specific fan power, as described in the 'Non-Domestic Heating, Cooling and Ventilation Compliance Guide – Section 10. External system resistances for air handling units and fans are given in the schedule.

Fans shall be centrifugal fans with backward curved aerofoil blades, and give an efficiency of not less than 78%.

Fans shall be positioned to 'blow through' the central plant so that the cooling coil and humidifier drains shall be under positive pressure.

Where a centrifugal fan is located with an open intake, the clear distance between the suction opening and the nearest wall should be not less than half the diameter of the inlet. If two fans with free inlets are positioned within the same chamber, their adjacent suction openings should be at least 1 diameter apart.

Fan/s and drive/s shall be provided with mounting frames and isolation mountings.

Motors shall be located externally. On externally driven fans, drive connection or belts shall be provided with airtight seals to prevent leakage. Externally driven fans shall have suitable anti-vibration mountings and frame with flexible connections to the fan sections of the unit. Fan-drive trains, whether supply or extract, should be easily visible without the need to remove access covers.

Fan drives shall be protected by a mesh guard.

All fans shall be controlled by inverter speed control drives supplied by the controls specialist.

Fans shall be capable of being direct start with fixed speed and manual operation in the event of a computer control system failure or software fault.

Particularly attention shall be given to critical care systems serving operating suites, high dependency care units of any type, isolation facilities, laboratories and pharmaceutical production suites in this regard.

- Performance: In accordance with BS 6583.
- Type of fan: Centrifugal.
- Motor mounting: The fan motor shall be external to the air stream.
- Blow through units: Arrange section to allow uniform velocity profile downstream.

Refer to Section U82.

405 ATTENUATOR

Where attenuators are located within the air handling unit they shall be the same cross sectional area as the AHU and have diffusion plenums as necessary.

Cleaning access should be provided at both ends of any attenuator unit.

Attenuators shall meet SHTM/HTM 2025/03-01 and this specification.

The splitters shall be fitted with 0.8mm mild steel galvanised bull nosed entries and exits to reduce pressure drop.

Normally the attenuators shall be installed with the splitters in the vertical plane. However in some circumstances, i.e. close to a vertical bend it may be necessary to install with splitters horizontally. In those circumstances the splitters shall be suitably stiffened to prevent flexing and restriction of the airway.

Refer to section U87.

FABRICATION

The Sub-contractor shall submit details of all mechanical equipment for comment and place orders in a timely fashion to ensure delivery as per programme

The Sub-contractor shall protect the AHU's from damage or interference during the works.

The AHU's shall be blanked off when delivered to site to prevent dust entering the AHU.

The Sub-contractor shall include for the services of the manufacturer's skilled services engineers to start up, test and check all the AHU's and controls. This shall include all tests to prove that all the AHU equipment is working with and responding to the clients BMS network and head end. The units when commissioned shall be "Set Up" to give maximum efficiency. The AHU's shall be witnessed by the Contractor before the plant shall be accepted from the Sub-contractor. The Sub-contractor shall allow for instruction of the

clients representative on the working of the equipment.

510 AIR HANDLING UNIT CASING CONSTRUCTION

Supply air handling plants shall be of a packaged construction with a double skin casing, complete with thermal/acoustic insulation material between the two skins. Units shall house filters, coils, fans and motorised inlet dampers, etc. Heat recovery devices shall also be incorporated as detailed in the AHU schedule.

Vibration isolation shall be provided in the form of spring anti-vibration mountings located under fan and motor bases with flexible connections from the fan discharge and the adjoining ductwork.

- Standard: To BS EN 1886.
- Details: The sub-contractor is to submit shop drawings and details of dimensions and weight for review.
- Thermal performance of casing, to form part of the technical submission.
- Acoustic insulation of casing: To form part of the technical submission.
- Fire protection: To form part of the technical submission.
- Material: To form part of the technical submission.
 - Finish: To form part of the technical submission.
- Air handling unit feet: Base to suit AHU and depth of drain and pipe fall.
- The Sub-contractor is to allow space to integrate the BMS controls into each air handling unit, to serve that respective AHU, and liaise with the BMS Specialist to integrate this.

520 AIR HANDLING UNIT ACCESS

- General: Provide access openings and covers complete, including opening devices.
- Seal: To prevent excessive air leakage.
- Seal durability: For normal maintenance operations over at least 10 years.
- Access type: Access doors/hatches as appropriate and where indicated on the drawings or called for in SHTMs, shall be provided complete with handles, locks, keys and latches to the same standards of construction and finish of unit.

Where the unit is large enough for a maintenance engineer to enter the unit, facilities for local maintenance isolation of equipment and opening the doors from the inside shall be provided.

The doors should be large enough e.g. 500mm minimum to allow easy access. Items requiring infrequent access such as attenuators may be via bolted on, lift off panels All doors/panels shall be provided with seals to prevent air leakage.

Access shall be provided as a minimum to fan chamber, dampers, filters, humidifiers and both sides of heating and cooling coils.

Internal lights and double glazed viewing windows shall be provided into fan chambers, either sides of coils, humidifier sections and where indicated on the drawings. Fittings within the unit shall be to IP55 standard and be operated from a single switch.

Additionally, the cladding shall be capable of being easily removed as is necessary to obtain access for necessary inspection and maintenance and also for removal of large items of equipment.

All necessary items shall be assembled by means of nuts, bolts, anti-vibration lock

washers or approved quick release fastenings. Access doors on isolation suite extract shall have biohazard label affixed.

EXECUTION

610 COMPONENT ASSEMBLY

- Sealing: Provide gaskets between air handling unit sections to prevent air leakage from casing.
- Site drilling of air handling unit: Not permitted.

620A ACCESS

- Access space: Position air handling units to allow space for maintenance and access.

Access for servicing shall be as manufacture recommendations and drawings.

As a minimum the Sub-contractor shall allow the width of the AHU for withdrawing the coils.

630 COIL INSTALLATION GENERALLY

- Venting and draining: Set out pipeline to and from the coils to allow venting and draining of the coils and piping.
- Support: Do not support pipeline and valves on coil connections.
- Access: Allow space to inspect and maintain the coils on both sides.

640 HOT WATER COILS INSTALLATION

- Expansion: Connect pipeline to allow free expansion of headers and tubes.

650A DRAIN LINES INSTALLATION

- All items of plant that could produce moisture must be provided with a drainage system.

The system shall comprise a drip tray, glass trap, air break and associated drainage pipework. All parts of the drainage system must comply with SHTM 03-01.

The drip-tray should be constructed of stainless steel, and be so arranged that it shall completely drain. To prevent 'pooling', it is essential that the drain connection should not have an up-stand; and that a slope of 1 in 20 in all directions should be incorporated to the drain outlet position. The tray must be completely accessible or, for smaller units, easily removable for inspection and cleaning.

Where traps are fitted to plant located outside or in unheated plant rooms trace heating shall be required. The trace heating must not raise the temperature of the water in the trap above 5°C.

660 SERVICES CONNECTIONS

- Entry points: Seal around electrical cable and pipeline entry points to prevent air leakage.

- Flexible cables: Provide between fan motor and local isolator.

670 ISOLATION OF AIR HANDLING UNITS

- Electrical connections: Provide means of isolating air handling units electrically.
- Pipe connections: Provide means of isolating pipelines to air handling units.
- Steam: Provide means of isolating steam to humidifier when access door is opened.

680 SUPPORT FOR AIR HANDLING UNITS

- Method: Purpose made raised frame, with sufficient clearance for drains and traps.

COMPLETION

During the flushing of the pipework system the AHU coil must be by passed or disconnected.

Under no circumstances shall the Sub-contractor flush through the coils

The units shall be supplied initially with one complete set of spare filters and a further set is to be offered for handover to the client at the end of the contract. This set should be carefully packed and labelled for each plant and filter type.

Alongside each filter gauge a permanent label is required with the following information:-

- Type (pre, bag, final etc.)
- Grade
- Size
- Clean PD (at full speed)
- Dirty PD (at full speed)

910 PRE-COMMISSIONING OF COILS

- Preparation:
 - Remove protective covering.
 - Check frost protection and drain if heat is not available in freezing conditions.
 - Straighten fins.
- Cleaning and chemical treatment: Use chemicals compatible with the materials in the coils.

920 AIR LEAKAGE TESTING

- Testing: In accordance with HEVAC Guide to air handling unit leakage testing.

930 TESTING

- Test location: On site before incorporation in works. (Selected factory testing/inspection may be carried out)
- Test results: Submit.

U82 FANS

PRODUCTS

All fans shall be type tested to BS.848 and a type test certificate shall be provided for each type of fan supplied. All fan duties shall be at an air density of 1.2 kg/m³ at 1.01325 bar and 15°C. Fan outlet velocities shall not exceed 10.00 m/s. Each fan shall be provided with dedicated fan performance curves, with the duty selection, absorbed power requirements, motor selection and sound power levels clearly indicated.

All fans shall be selected for low noise.

All fans shall be low energy type.

All fan's and system controls must be capable of being fully interrogated by the building management system through the independent network protocol.

All fans are to be inverter driven.

310 AXIAL FLOW FANS

Axial flow fans shall be of the long case pattern with a heavy gauge mild steel casing galvanised after fabrication, flanged and drilled at each end.

The impeller shall be of multi-blade aerofoil section constructed from die cast aluminium or heavy-duty steel. The hub design shall allow for manual adjustment of the blade pitch angle. Multi-stage axial fans shall be arranged with contra-rotating stages.

The impellers shall be directly driven through a totally enclosed motor with ball or roller bearing to suit the application. The fan motor shall be sized so that a blade pitch angle adjustment of the impeller of up to 2° shall be possible without a change of motor. During assembly of each fan the fan impeller shall be statically balanced to a level of 4.5 mm/s RMS at the fan feet. All bearing lubrication shall be extended to the outside of the casing. Axial fans shall be complete with anti-vibration mounts, flexible connections and matching flanges for duct connection and bellmouths and guards where fans are in free air. Motor terminal boxes shall be external to the casing and provide protection to IP55 as defined in BSEN.60529.

- Performance: To BS 848-1.
- Sub-contractor to provide technical proposals for review.
- Mechanical safety: To BS 848-5.
- Electrical safety: To BS EN 60335-2-80.
- Dimensions: To BS 848-4.
- Operating conditions:
 - Environment: Sewerage works nearby.
 - Air density: 1.20 kg/m³.
- Operation: As schedule and drawings.
- Inspection doors: Fit airtight inspection doors giving access to drive motors and other components requiring regular servicing and maintenance.
- Motor and drive: Match fan.
- Material:
 - Casing: Manufacturer's standard. Sub-contractor to submit proposals.

- Impeller: Manufacturer's standard.
- Anti-vibration mountings: Manufacturer's standard. Sub-contractor to submit proposals.
- Flexible duct connections: Manufacturer's standard. Sub-contractor to submit proposals.
- Accessories: As schedule and drawings.

320 CENTRIFUGAL FANS

Fan units shall be installed as detailed on drawings and fan schedules. External fans shall be weatherproofed and suitable for conditions.

The assembly is dynamically balanced to DIN ISO 1940. Motors shall be constructed from aluminium and be suitable for speed control.

Fans shall be suitable for horizontal through to vertical shaft operation. Supplied IP55, with removable drain plugs.

Sealed for life bearings lubricated with wide temperature range grease. Motors shall be fitted with thermostat overheat protection as standard. Three phase motors shall be suitable for inverter speed control down to 20% of full speed where specified.

Fans shall be fully cased, complete with an externally mounted pre-wired electrical terminal box. Casings shall be from sheet steel with integral pre-drilled inlet flanges.

Casings shall have a galvanised finish to provide a high corrosion resistance

- Performance: To BS 848-1.
- Sub-contractor to provide technical proposals for review.
- Mechanical safety: To BS 848-5.
- Electrical safety: To BS EN 60335-2-80.
- Dimensions: To BS 848-4.
- Operating conditions:
 - Environment: Sewerage works nearby.
 - Air density: 1.20 kg/m³.
- Operation: As Fan schedule.
- Motor and drive: Match fan.
- Casing: Manufacturer's standard. Sub-contractor to submit proposals.
- Inspection doors: Fit airtight doors in scroll and cover.
- Mounting: As Fan schedule and drawings.
- Material Galvanized sheet steel.
- Anti-vibration mountings: Manufacturer's standard. Sub-contractor to submit proposals.
- Flexible duct connections: Manufacturer's standard. Sub-contractor to submit proposals.
- Accessories: As Fan schedule.

350 ROOF MOUNTED FANS

The roof mounted extract/supply fans shall be located in the positions indicated on the drawings and in accordance with the relevant fan schedule. It shall be a low profile cowl manufactured in flame retardant GRP.

The roof fan shall suit the roof profile.

The fan shall be supplied complete with backdraught shutters, bird guard, purlin box curb,

hand guard, specific details of the curb and purlin shall be confirmed by the main Sub-contractor.

The Sub-contractor shall make due allowance for supporting the fan via the provision of purpose made trimmers between purlin. The trimmers shall be sized to adequately support the weight of the fans.

The fan shall be supplied with all the control interfaces to integrate with the clients BMS system.

- Performance: To BS 848-1.
 - Inlet and outlet arrangement: Sub-contractor to provide technical proposals for review.
- Sub-contractor to provide technical proposals for review.
- Mechanical safety: To BS 848-5.
- Electrical safety: To BS EN 60335-2-80.
- Dimensions: To BS 848-4.
- Operating conditions:
 - Environment: Sewerage works nearby.
 - Air density: 1.20 kg/m³.
- Operation: As Fan schedule and drawings.
- Motor and drive: Match fan.
- Anti-vibration mountings: Manufacturer's standard. Sub-contractor to submit proposals.
- Flexible duct connections: Required.
- Flexible electrical connection: Fans electrical power shall be rated for outdoor use.
- Accessories: As Fan schedule.

355 SMOKE EXTRACT FANS.

Fans shall be the bifurcated type are indicated or required, the motor shall be outside the airstream. Motors may be placed between the two halves of the casing using ambient air for motor cooling. Where hot gases, vapours or corrosive fumes are being handled, the motor bearings shall be suitable for operation at the temperatures resulting for the processes involved.

Fans shall be specially constructed for the temperature and the running duration specified during Fire/smoke condition.

- Standard: To BS EN 12101-3.
- Sub-contractor to provide technical proposals for review.
- Electrical safety: To BS EN 60335-2-80.
- Accessories:
 - Flexible connections: Required.
 - Vibration isolators: Manufacturer's standard. Sub-contractor to submit proposals.
- Control: As schedule.
- Starting device: As schedule.

360 TOILET EXTRACT FANS

Dirty extract systems shall be provided with dedicated extract fans. The fans shall be arranged for duplicate operation in a run and stand-by configuration.

The fans shall be of the centrifugal type with forward curved blades. The impellers shall be

belt driven.

Each fan shall have its own dedicated motor and drive assembly mounted on a common base frame with spring anti-vibration mounts between the frame and the unit case/framework.

The fans shall be arranged for auto changeover achieved via the BMS. On failure of the duty fan the stand-by shall start and run. The changeover shall also include the automatic activation of backdraught dampers. The fan enclosure shall be configured to allow continuous operation of the stand-by fan while the failed unit is removed for repair or replacement. The fan and motor shall be removed as a common assembly.

The fans shall be housed in a common heavy gauge aluminium casing arranged for ducted inlet and outlets.

The units shall be provided with airflow and failure monitors suitable for interfacing with the BMS. Auto changeover shall be undertaken by the BMS.

- Performance: To BS 848-1.
 - Inlet and outlet arrangement: As drawings.
- Manufacturer: Sub-contractor to provide technical proposals.
 - Product reference: Sub-contractor to provide technical proposals.
- Sub-contractor to provide technical proposals for review.
- Electrical safety: To BS EN 60335-2-80.
- Operation: As schedule
- Electrical supply type: As schedule.
- Accessories:
 - Access panel: Removable panel
 - Controls: Speed controller to match fan, refer to BMS for further details.
 - Silencer.
 - Backdraught damper.
 - Anti-vibration mount.
 - Guards.

370 CONSTRUCTION AND HANDLING

- Casings: Rigid, so there is no drumming under operating conditions.
- Lifting: Provide lifting eyebolts or similar facilities on fans or sections heavier than 20 kg.

EXECUTION

610 INSTALLATION

- Fixing: Use fixing points provided. Do not strain the fan structure when bolts are tightened.
- Orientation: Mount impeller shaft horizontally.
- Alignment: Install fan to allow optimum air flow path.

U83 AIR FILTRATION

PRODUCTS

Filters may be provided in separate plant section of the air handling unit or, if specified, as part of a common section. Filter banks shall be provided with mounting frames to suit standard commercially available filter cells, arranged for side or front withdrawal as per schedules.

Air filter shall be constructed shall not be capable of supporting combustion.

Gauges shall be provided across each filter. Tees and branch tubing should be fitted so that the controls specialist to fit a separate dirty filter warning pressure switch.

All filters shall have a Filter dirty alarm to the BMS.

Alongside each filter gauge a permanent label is required with the following information:-

- Type (pre, bag, final etc.)
- Grade
- Size
- Clean PD (at full speed)
- Dirty PD (at full speed)

One complete spare set of filter media for each plant shall be provided at handover, being carefully packed for storage and labelled for respective plant and filter types.

The Sub-contractor shall supply and install services and equipment to perform as per specification. The Sub-contractor shall submit details of all mechanical equipment for comment and place orders in a timely fashion to ensure delivery as per programme.

Where a particular manufacture is specified, the Sub-contractor shall include for that manufacturer.

Where considered appropriate, provide for equivalent standard alternatives to be offered for consideration.

This must be done in a timely manner and the Sub-contractor shall provide all details including but not limited to.

- Detailed description
- Cost comparison
- Technical comparison
- References to standards

310 PRIMARY FILTERS

Filter media shall be manufactured from 100% recycled materials. Filter media shall be a cotton and synthetic blend, lofted to a uniform depth, and formed into a uniform radial pleats.

A welded wire grid, treated for corrosion resistance, shall be bonded to the downstream side of the media to maintain the radial pleat and prevent media oscillation.

An enclosing frame, of biodegradable board shall provide a rigid and durable enclosure.

The frame shall be bonded to the media to prevent air bypass.

The manufacturer shall provide evidence of facility certification to ISO standard.

- Performance: To BS EN 779.
- Filter type: Sub-contractor to submit proposals.
- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Duty:
 - Air flow rate: Sub-contractor to submit proposals.
 - Air velocity: Sub-contractor to submit proposals.
 - Initial filter pressure drop: Sub-contractor to submit proposals.
 - Final filter pressure drop: 150 Pa.
 - Filter class: As schedules.
 - Filter height, width and limiting depth: As schedule and drawings.
 - Conditions: Sewerage works nearby.
- Flammability: Non-flammable for duration of recommended working life.
- Casing: Manufacturer's standard.
- Access: As specification.
- Filter mounting frames: Purpose made, rigid, with building-in ties where filter is mounted in walls or partitions.
- Allow for future upgrade to grade F7 bag filter when carbon filter is fitted.

320 SECONDARY FILTERS

Bag or extended surface type filters shall be provided to the required grade or better as specified, in the Equipment Schedules with maximum air velocity at face not exceeding 2.5 m/s. Filter media shall be manufactured from 100% recycled media.

Filters shall be fully self-supporting without external ties or stiffening frames. Filters shall inflate fully, shall not sag or flutter, nor have effective medium area reduced by obstruction due to contact with other filter faces or housing surfaces when operating between 60% and 110% of design air volume for constant volume systems or between the specified minimum and maximum air volume rates for multi-speed systems. Bag shall be short or normal length as noted in the Schedule of design criteria.

- Performance: To BS EN 779.
- Filter type: Bag.
- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Duty:
 - Air flow rate: Sub-contractor to submit proposals.
 - Air velocity: Sub-contractor to submit proposals.
 - Initial filter pressure drop: Sub-contractor to submit proposals.
 - Final filter pressure drop: 250 Pa.
 - Filter class: Sub-contractor to submit proposals.
 - Filter height, width and limiting depth: Sub-contractor to submit proposals.

- Flammability: Non-flammable for duration of recommended working life.
- Casing: Rigid.
- Access: Sub-contractor to submit proposals.
- Filter mounting frames: Purpose made, rigid, with building-in ties where filter is mounted in walls or partitions.
 - Material: Sub-contractor to submit proposals.

330 HIGH EFFICIENCY PARTICLE ARRESTOR (HEPA) FILTERS

High efficiency particulate air filters (HEPA/absolute) shall remove virtually all particles from air.

HEPA filters shall be H14 (EU 14) (unless otherwise Specified) with an efficiency of 99.995% @ MPPS.

HEPA filters shall be of the replaceable panel type with leak proof seals. They shall be installed in a manner that permits on site validation of the filter and its housing. This shall involve the release of a Dispersed Oil Particle (DOP) challenge smoke through an injection point upstream of the filter and a measurement of the DOP penetration across the downstream face.

A photometer shall be used to detect leaks.

The Method of testing/Validation with DOP shall be as set out in HTM 03-01.

Filter housing and seal (generally Housing shall be Electro zinc plated steel painted white RAL 9010, seal shall be Silicone or Polyurethane gel) shall be suitable for application.

- Standard: To BS EN 1822.
- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Use of conditioned space: Sub-contractor to submit proposals.
- Duty:
 - Maximum air flow rate: Sub-contractor to submit proposals.
 - Air velocity: Sub-contractor to submit proposals.
 - Filter height, width and limiting depth: Sub-contractor to submit proposals.
- Filter media: HEPA filter media - Group H.
- Filter class: H14.
- Filter casing: Provide with gasket fitted to casing.
- Filter material: As above.
- Flammability: Non-flammable for duration of recommended working life.
- Access: Access shall be provided for filter change and DOP test.
- Filter frame material: To suit application, as schedule.

350A IMPREGNATED CARBON FILTERS (INFORMATION FOR SPACE ALLOCATION ONLY)

Due to the Hospital site being in the same district as the Scottish water Sewerage works it is considered that large amounts of natural ventilation is not a practical solution.

The Sub-contractor shall allow for a specialist consultant to test the air and advise on the type of impregnated carbon to be utilised.

Carbon filters shall remove gases and vapours from the air stream and are graded

according to the range of substances they can remove.

Carbon filters shall be impregnated carbon suitable for the atmosphere on the site.

The carbon used shall have the correct dwell time for the conditions. This shall include the sewage works and the helicopter exhaust.

All kitchen extract fans shall also be provided with carbon filters.

The Sub-contractor's specialist shall also select filters for these systems.

- Manufacturer: Sub-contractor to submit proposals.
 - Product reference: Sub-contractor to submit proposals.
- Duty:
 - Air flow rate: Sub-contractor to submit proposals.
 - Air velocity: Sub-contractor to submit proposals.
 - Initial filter pressure drop: Sub-contractor to submit proposals.
- General: Provide absorbent bed filled with uniform thickness of activated carbon granules constructed to prevent settlement. Provide bonded carbon cells to prevent pinholing.
- Media type: Sub-contractor to submit proposals.
- Casing: Provide casing with removable panels.
- Casing material: To suit application, as schedule.

370 EDGE SEALS

- Function: Prevent air by-passing filters. Seals must remain effective after removal and replacement of cells.

380 PRESSURE GAUGES

Each filter shall have a Filter dirty alarm Filter status and Filter dirty alarm. This shall be compatible with the client BMS system:

- Type: Dial.
- Manufacturer: Sub-contractor to provide technical proposals.
 - Product reference: Sub-contractor to provide technical proposals.
- Gauge markings: Positions equivalent to 'Filter Dirty' and 'Filter Clean' conditions.
- Pressure differential switch: Provide for visual or audio warning of 'Filter Blocked Condition'.

390 TERMINAL FILTER HOUSINGS

- Terminal filter housing shall be easy to maintain, clean housing, able to accept a range of standard diffusers and grilles. The diffuser and colour shall match the other supply and extract diffusers.

Before any HEPA filters are installed the ductwork system shall be suitably clean.

The terminal housings shall have:

Polyester power coat finish
Limited travel filter clamps

DOP/Pd sample port
Installation hanging brackets
Fully welded flange
Top or side circular inlet

Damaged filters must not be install in the system.

- Filters housed: HEPA and ULPA.
- Housing seals: Gaskets between holding frames on banks of filters. Seal filters into steel casing.

395 FILTER SAFE-CHANGE UNITS

Where indicated on the drawings supply and install safe change housings complete with all pre and main filters. All housings to be manufactured from seam welded carbon steel with 2 pack epoxy coat finish.

Each filter assembly shall have the following features:-

- Inlet and outlet ductwork connections and support feet.
- Inlet and outlet tight shut off dampers.

Tight shut off dampers shall have seals to KTA 3601 or DIN 25414 (maximum leakage 0.01m³/hr x m² with a pressure differential of 2000Pa). The dampers shall be pressure tight to 5000Pa. The damper mechanism shall be designed such that after closure no energy is required to keep the damper in a closed position. The case and blades of the unit shall be constructed of sheet stainless steel to BS 1449 – Grade 304 – S11 Finish 2B. Bearing assemblies shall be stainless steel or brass. Damper blade sealed shall be neoprene foam rubber material, temperature resistant up to 80°C.

- Manometer points across each filter housing with manometer fitted across the hepa filter. Tappings to be configured to allow for BEMS monitoring of hepa filter condition. Manometer to be mounted on the assembly framework.
- 2 No. stainless steel cam bars for filter location.
- Aerosol sampling point in bottom spigot.
- All necessary safe change bag and retaining ring sets.
- All filter assemblies shall be factory pressure tested to a pressure of 2500Pa for minimum 1 hour and a test certificate provided.
- Leak test devices to DIN 1946 shall also be provided to allow maintenance staff to ensure replacement filters are properly seated prior to operation.

Each unit shall have:

- Minipleat high capacity absolute filters, 610 x 610 x 292mm deep with MDF case, efficiency to BS EN 1822 grade H14, 99.995%. All filters throughout the development shall be a common grade.

- Hardened case pre-filters 610 x 610 x 60mm to BN 779 grade G7.
- Upon completion of installation, a site validation test shall be carried out to achieve a maximum of 0.005% penetration and certificate provided.

EXECUTION

610 INSTALLING FILTER FRAMES

- Fixing: Securely fasten frames to ductwork walls.
- Gaps around the frames: Seal with mastic sealant.

620 INSTALLING FILTERS

- Mounting: Clamp securely against sealing gasket to prevent leaks.

630 INSTALLING PRESSURE GAUGES

- General: Fix external to unit to allow easy observation, within 3 m of filter.

U84 HEATING AND COOLING COILS

PRODUCTS

To facilitate maintenance access, auxiliary wet batteries should be located above corridors or other non-critical areas and not above patient occupied spaces. Access doors shall meet the requirements in section U80.

310 LOW TEMPERATURE HOT WATER HEATING COILS

Hot water coils shall be installed as shown on drawings.

Tubes are arranged in a staggered pattern with respect to adjacent rows to provide maximum heat transfer efficiency.

Return bends are the full thickness and diameter of the coil tubes to provide unrestricted flow and undiminished strength. Access for cleaning must be provided to both sides of all coils and batteries.

All water batteries shall be designed to ensure equal flow through all circuits. The water flow and return connections together with the airflow direction shall be permanently marked on the casing. All coils shall be supplied complete with vents and drains. Provision shall be made for expansion of the tubes and for effective venting of the coils.

Coils shall be arranged so as to facilitate removal of the coils without draining local pipework

On large coils, multiple or split coils shall be used to ease installation, repair and maintenance operations.

Heat exchanger finned surfaces shall extend the full width of the coil casing. Coils shall be suitably protected against corrosion with due regard to the geographical location of the coil and local atmospheric conditions. Sealing devices shall be provided around the casing to prevent air by-pass

Casings shall be galvanised sheet steel with angle framing at each end drilled ready to receive the counter flanges on the connecting ductwork. Coils shall be supported so that their weight is not transmitted to ductwork and so they can be removed without disturbing adjacent ductwork. Inspection doors shall be provided on both the upstream and the downstream sides of the coils.

All coils shall be tested at the manufacturer's works or an approved testing laboratory and rated for thermal performance to BS EN 13053 and certificates provided. These tests shall also include confirmation of water pressure drops at the design flow rates. These pressure drops shall be from pipework pressure topping on the flow and return connections external to the unit.

The maximum water system pressure drop shall be 25 kPa. The maximum air pressure drop across the coil shall be 20 Pa. Any site tests that show either pressure drops above this level shall require the replacement of the coil.

Where auxiliary/ret - heater-batteries are located in false ceilings, they should be fitted

with a catch tray and leak detection alarm. The catch tray shall be installed under both the battery and the control valve assembly to protect the ceiling from leaks. The moisture sensor and alarm shall be fitted in the tray and shall alarm the clients BMS in the event of a leak.

- Performance: To BS 5141-2 and BS EN 1216.
- The Sub-contractor shall submit proposals for review.
- Materials: Solid drawn copper tubes with copper fins.
- Tube wall thickness: At least 0.7 mm.
- Fin thickness (minimum):
 - Aluminium: 0.4 mm.
 - Copper: 0.3 mm.
- Fin spacing (maximum): As schedule.
- Thermal expansion: Allow for movement.
- Casing finish: Galvanized mild steel.
- Access doors: Hinged, airtight and watertight for maintenance.
- Draining and venting: As specification.
- Water test pressure: Up to 2.1 MPa or 1.5 times the working pressure, whichever is greater.
- Packaging: Fit protection for fins before despatch.
- Protection: Fit blank flanges or caps to pipe connections after manufacture.
- Accessories: As schedule.

320 CHILLED WATER COOLING COILS

Access for cleaning must be provided to both sides of all cooling coils. The coil shall have electro tinned fins.

Coils frames and casings shall be manufactured from stainless steel.

Pipe Connections shall be screwed up to 50mm, flanged above. Maximum velocity over the coils shall be 2m/s.

The coil shall have an eliminator.

All cooling coils shall be fitted with their own independent drainage system. The system shall comprise of a stainless steel drip-tray, glass trap, air break and associated drainage pipework.

The drip tray shall be arranged to drain completely and prevent pooling.

The drain connection shall not have an up-stand. A slope of 1 in 20 in all directions shall be incorporated to the drain outlet position.

Where coils are greater than one metre high intermediate drain trays shall be provided.

The AHU base shall be high enough to accommodate the trap and pipe work fall.

The tray shall be completely accessible or for inspection and cleaning.

Each drip-tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type.

The trap should have a means for filling and should incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it shall not be subject to casual knocks. The pipework connecting it to the drainage tray should have a continuous fall of not less than 1 in 20.

Water from each trap must discharge via a clear air gap of at least 15 mm above the unrestricted spill-over level of either an open tundish connected to a drainage stack via a second trap, or a floor gully. A support should be provided to ensure that the air gap cannot be reduced. Drainage pipework shall be copper.

A baffle or similar device must be provided in the drip-tray to prevent air bypassing the coil, and the tray should be large enough to capture the moisture from the eliminator, bends and headers.

The cooling-coil control valve should close upon selection of low speed, system shut-down, low airflow or fan failure.

The maximum water pressure drops across the coils shall be 30 kPa. The maximum air pressure drops across the coils shall be 80 Pa. Any site tests that show pressures above either of these levels shall require the replacement of the coil.

- Performance: To BS 5141-1 and BS EN 1216.
 - Duty: Refer to drawings and schedules.
 - Materials: Solid drawn copper tubes with copper fins, all electro-tinned.
 - Tube wall thickness: At least 0.7 mm.
 - Fin thickness (minimum):
 - Aluminium: 0.4 mm.
 - Copper: 0.3 mm.
 - Casing:
 - Finish: Stainless steel
 - Return bends: Provide removable covers. Lag and vapour seal the bends.
 - Eliminator plates: Install downstream of all coils.
 - Draining and venting: As specification.
 - Access doors: Hinged, airtight and watertight for maintenance.
 - Water test pressure: Up to 2.1 MPa or 1.5 times the working pressure, whichever is greater.
 - Packaging: Fit protection for fins before despatch.
 - Protection: Fit blank flanges or caps to pipe connections after manufacture.
 - Accessories As schedule.
- Airflow: Evenly distributed over face area of coil (to be verified at commissioning)
 - Air velocity: Ensure it is below level at which moisture carryover occurs.

340 ELECTRIC HEATER BATTERIES

Generally electric heating batteries are to be avoided. Their use should be restricted to low power use (for example trimming control).

Where used, electric heaters shall be provided with high temperature cut out protection with automatic reset.

The Sub-contractor is to provide technical submissions for review.

- Casing material: Aluminium.
 - Casing finish: Natural.
- Access doors: Hinged, airtight and watertight for maintenance.
- Heating elements: Mount on removable terminal plate.
 - Type: As schedule.
- Terminal boxes: Welded steel.
- Safety cut-out switch: Automatic reset, wired in series or via contactor with heating elements.
- Controls:
 - Fan interlock to prevent heater operating without fan running.
 - Run-on timer to allow airflow to cool heater before switching off fan.
- Air flow detector switch: Wired in series with other safety devices.
 - Type: Differential pressure.
- Accessories: Heater batteries to be thyristor controlled.

EXECUTION

During the flushing of the pipework system all coils must be by passed or disconnected. Under no circumstances shall the Sub-contractor flush through the coils

610 INSTALLATION

- Equipment, controls and instruments positioned next to heating coils: Protect from thermal radiation.
- Fixings: Support coils independently of ductwork.

620 ELIMINATOR PLATES INSTALLATION

- General: Fit to allow removal from coil casing.

630 DRAIN TRAP INSTALLATION

- Air break: Locate between trap outlet and drainage system.
- Traps under suction: Install the outlet below the inlet by a depth equivalent to at least one and a half times working pressure.
- Traps under positive pressure: Install inlet and outlet at same level.

U85 HEAT RECOVERY

Thermal wheel heat exchangers shall be incorporated within extract air plants handling uncontaminated air (non hygro-scopic type). These plants shall also include main dirty air extract plants. The heat exchangers shall transfer heat energy within the extract air to a pumped circulation water heat recovery system. Heat exchangers within the fresh air plants shall utilise the recovered heat to pre-heat incoming fresh air.

Where the use of thermal wheel heat recovery units have been found to be inappropriate plate recuperator systems are to be employed.

The heat recovery systems shall be configured to operate at all times when useful energy can be recovered and used by the various air plants.

PRODUCTS

310 PLATE RECUPERATORS

- The Sub-contractor is to submit proposals for review based upon details shown on drawings, schematics and schedules.
- Efficiency: minimum 55%.
- Heat transfer plates: Manufacturer's standard for application. Sub-contractor to provide technical submission.
- Coating: Manufacturer's standard for application.
- Access doors: Hinged, airtight and watertight for maintenance.
- Accessories:
 - Face and bypass dampers;

330 THERMAL WHEELS

- The Sub-contractor is to submit proposals for review based upon details shown on drawings, schematics and schedules.
- Efficiency: minimum 65%.
- Rotor: Non-hygroscopic.
- Access doors: Hinged, airtight and watertight for maintenance.
- Accessories:
 - Adjustable purging sector;
 - By-pass damper;
 - Matching ductwork flanges;
 - Return air damper; and
 - Speed controller.

EXECUTION

630 INSTALLING DRAIN TRAPS

- Air break: Locate between trap outlet and drainage system.
- Traps under suction: Install the outlet below the inlet by a depth equivalent to at least one and a half times working pressure.
- Traps under positive pressure: Install inlet and outlet at same level.

U86 AIR TREATMENT

Full humidity control, including humidification and dehumidification, shall be provided only in critical air-conditioned clinical areas such as the Pharmacy Aseptic Suite or wherever close control of humidity is required for the successful operation of sensitive equipment, e.g. computers.

Only steam injection manifold-type humidifiers are considered suitable for use in health building air-conditioning systems. Water humidifiers of any other type shall not be used.

The local steam generator must be fed with potable quality water. Should the humidifier be unused for a period exceeding 48 hours, it must be capable of automatically draining its water content, including that contained in the supply pipework, right back to the running main and leave itself empty. The humidifier shall have overriding controls separate from the normal plant humidistat.

Their purpose is to prevent excessive condensation in the conditioned space when starting up. A time delay shall be incorporated into the humidifier control system such that the humidifier does not start until 30 minutes after the ventilation/plant start-up. In addition, a high limit humidistat shall be installed to limit the output of the humidifier so that the saturation in the duct does not exceed 70%.

The humidifier control system should ensure that the humidifier is switched off when the fan is not running.

- Type: Steam from self contained boiler.
- Water quality: As schedule.

PRODUCTS

310A STEAM HUMIDIFIERS

- Manufacturer: The Sub-contractor is to submit proposals for review.
 - Electrical supply type: Three phase.
- Steam source: Local Electric.
- Safety of appliance: To BS EN 60335-2-88.
- Material: Corrosion resistant.
- Access doors: Hinged airtight and watertight for maintenance.
- Safety signs: On access door, a label reading 'Isolate steam supply before opening' in letters at least 25 mm high.
- Accessories: Manufacturer's standard

EXECUTION

610 INSTALLATION

- Discharge: Install humidifiers so that air flow is uniform over cross-section of ductwork.
- Position: Do not install next to air heating coils.

620 CONDENSATE CONNECTIONS

- General: Arrange condensate lines so that back pressure does not exceed manufacturer's recommendations.

630 THERMAL EXPANSION

- General: Connect pipelines to take up thermal expansion without stressing humidifiers.

640 INSTALLING DRAIN TRAPS

- Air break: Locate between trap outlet and drainage system.
- Traps under positive pressure: Install inlet and outlet at same level.

650 FIXINGS

- General: Support humidifiers from building structure on zinc coated steel supports, independently of adjacent ductwork. Provide separate supports for components mounted outside casings.

U87 SILENCERS AND ACOUSTIC TREATMENT

PRODUCTS

The attenuators including cross talks, shall be selected and installed by the Sub-contractor. The Sub-contractor shall appoint a specialist to select these, using the noise criteria detailed elsewhere. The permissible pressure drop on cross talk attenuators is 25 Pa and 50 Pa on other attenuators. The Sub-contractor is to provide technical submissions for the silencers and acoustic treatment.

310 CIRCULAR SILENCERS

Silencers shall be installed generally as indicated on the drawings.

Silencers shall be of the size, configuration, capacity and acoustic performance required to meet the specified acoustic criteria.

All circular silencers shall be constructed with a galvanized steel casing. All casing seams and joints shall be lock formed and sealed. All fixings to the casing to be with blind rivets to eliminate leakage.

The silencer infill to be covered in ICI Melinex or similar to prevent particle migration. The membrane shall have a 25 year service life.

- Performance requirements: To BS EN ISO 7235 and BS EN ISO 11691.
- Casing: galvanised sheet steel minimum thickness 0.8mm
- Splitters: galvanised perforated sheet screen minimum thickness 0.8mm with an open area of at least 23%.
- Lining material: Inert, fire proof, inorganic and non- hygroscopic minimum density 48kg/m³.
- Markings: Show direction of air flow on silencer.

320 RECTANGULAR SILENCERS

Silencers shall be installed as indicated on the drawings.

Silencers shall be of the size, configuration, capacity and acoustic performance required to meet the specified acoustic criteria.

All Rectangular silencers shall be constructed with a galvanized steel casing. All casing seams and joints shall be lock formed and sealed. All fixings to the casing to be with blind rivets to eliminate leakage.

The silencer infill to be covered in ICI Melinex or similar to prevent particle migration. The membrane shall have a 25 year service life.

- Performance requirements: To BS EN ISO 7235 and BS EN ISO 11691.
- Casing: galvanised sheet steel minimum thickness 0.8mm
- Splitters: galvanised perforated sheet screen minimum thickness 0.8mm with an open area of at least 23%.
- Lining material: Inert, fire proof, inorganic and non- hygroscopic minimum density 48kg/m³.
- Markings: Show direction of air flow on silencer.

330 AIR TRANSFER AND CROSS TALK ATTENUATORS

Cross Talk attenuators shall be installed in the ductwork in locations shown in the plans.

The performance of the attenuators is to be such that the privacy to be maintained between adjacent spaces.

The attenuator shall control noise in particular speech via the ductwork.

The Sub-contractor shall submit calculations for examination *by the acoustic consultant*.

All cross talk silencers shall be constructed with a galvanized steel casing. All casing seams and joints shall be lock formed and sealed. All fixings to the casing to be with blind rivets to eliminate leakage.

The silencer infill to be covered in ICI Melinex or similar to prevent particle migration. The membrane shall have a 25 year service life.

- Performance requirements: To BS EN ISO 7235 and BS EN ISO 11691.
- Casing: galvanised sheet steel minimum thickness 0.8mm
- Splitters: galvanised perforated sheet screen minimum thickness 0.8mm with an open area of at least 23%.
- Lining material: Inert, fire proof, inorganic and non- hygroscopic minimum density 48kg/m³.
- Markings: Show direction of air flow on silencer.

The cross talk attenuator shall be installed / located to avoid flanking ideally places in the ductwork as it passes through the wall separating rooms.

350 ACOUSTIC INSULATION

The Sub-contractor's acoustic specialist shall examine the need for acoustic lagging. Acoustic lagging shall be provided and fitted where necessary to the outside of the ductwork to achieve an enhanced Sound Reduction Index (SRI) of ductwork and hence reduce noise break in or break out.

The lagging shall consist of mineral wool density not less than 48kg/m³ and not less than 50mm thick.

The mineral wool shall be covered with an outer skin typically lead weighed PVC material or 0.8mm thick galvanised mild steel. All joints shall be suitably sealed to maintain acoustic integrity.

The lagging shall be securely fixed to the pipework / ductwork using mechanical fixings.

- Material: Lightweight mineral wool.
- Outer covering: As specification.

EXECUTION

610 ACOUSTIC LININGS

- Access: Where personnel access is provided, protect acoustic linings to prevent damage.

U88 AIR TERMINAL DEVICES

PRODUCTS

Air terminals shall be provided as indicated on the drawings, or as defined further in this specification.

The Sub-contractor shall co-ordinate the reflected ceiling plan.

The Sub-contractor shall appoint a specialist supplier to provide the selections and schedules for the air terminal devices. The Sub-contractor's specialist shall select the grilles and diffusers using the locations and air volumes shown on the drawing. The Sub-contractor shall submit these for review.

All diffusers and grilles shall be selected for quiet operation, using the noise criteria specified.

The Sub-contractor shall provide samples of each type of air terminal device for review.

Neck velocity shall not exceed 2.5 m/s on any terminal device (diffusers/grilles etc).

310 AIR TERMINAL DEVICES, SPECIALIST UCV HOODS

The UCV shall be a Vertical-flow type system and meet all requirement of SHTM/HTM 2025/03-01 including table 6.

The return air grilles/diffusers shall be sited so as not to cause short circuiting. The Sub-contractor shall comply with SHTM/HTM 2025/03-01 to this regard.

The Sub-contractor shall ensure that each face or each corner of the theatre shall have an air path to provide good air circulation and to prevent entrainment in the clean zone. Air velocities for and over the UCV shall be as SHTM/HTM 2025/03-01 as a minimum. UCV systems shall come complete with HEPA filters. A set of new filters shall be issued to the client following commissioning of the unit.

The final filters shall be installed in a leak-proof housing in a manner that allows the terminal unit, filters and their seals to be validated. A challenge test shall be carried out during commissioning to prove the effectiveness of the complete installation. Challenge test shall be as manufactures recommendations and the Method of testing/Validation with DOP shall be as set out in HTM 2025/03-01.

The UCV shall have direct-reading pressure gauges for each final filter and a return-air filter to capture the relatively coarse particles that would otherwise significantly reduce the life of the final filter. The return air filter shall be G3 grade to BS EN 779 as a minimum.

The UCV shall not exceed NR 50. Any in line attenuation shall non-particle-shedding and fire-resistant.

Lighting for the UCV shall be as CIBSE lighting guide LG2 and BS EN 12464-1.

Operating luminaires should comply with the photometric requirements detailed in relevant sections of BS EN 60601.

The lighting level shall be even throughout and luminaries shall not adversely affect the air flow.

The functions of the canopy circulation fans shall be continuously monitored by a BMS control unit.

Additional to this the UCV system shall have

- a set-back facility that shall reduce the air supplied through the UCV terminal to a volume that equates to an amount not less than 25 air changes per hour of the operating room's gross volume whilst still leaving the supply AHU operating at full speed;
- a facility to turn off the entire system, the supply AHU and the UCV terminal (an emergency stop is not required);
- a read-out sufficiently large to be clearly visible from the operating table that shows the temperature of the air being supplied by the UCV terminal;
- a read-out sufficiently large to be clearly visible from the operating table that shows the relative humidity of the air being supplied by the UCV terminal;
- a red indicator light that shall illuminate when either the supply AHU or the UCV terminal fails; either or both are switched off or the AHU and UCV terminal are at set-back;
- an amber indicator light that shall illuminate when the UCV terminal is at set-back and the supply AHU is running;
- a green indicator light that shall illuminate when both the supply AHU and UCV terminals are operating at full speed;
- a blue indicator light that shall illuminate when the UCV terminal's HEPA-filter resistance causes the air delivered to fall below 80% of the design flow rate.
- Performance:
 - Mixed flow applications: To BS EN 12238.
 - Sound power levels: To BS EN ISO 5135.
- Performance requirement to SHTM.
- Material: Stainless steel.

325 AIR TRANSFER GRILLES

Transfer grilles shall be non-vision type and sized for a maximum face velocity of 1.5 m/s.

- Grille type: Non-vision.
- Accessories: Transfer grilles shall not be installed in a fire rated door/wall.
Transfer grilles in operating theatres shall incorporate a volume control damper to allow adjustment to room pressure

330 DIFFUSERS

Ceiling diffusers shall be installed as shown on the drawings. The diffuser shall be a square ceiling diffuser for flush mounting, comprising diffuser face with mitred perimeter border.

Louvre face diffusers shall be of the four way pattern and shall have adjustable cores to provide horizontal or vertical distribution. The air pattern shall be achieved via the use of directional blanking plates within the body of the diffuser and shall not be visible from the diffuser face. The diffuser shall be suitable for incorporation in a standard ceiling tile grid

without overlapping the tile-supporting bar. Diffusers shall be complete with a security chain between the diffuser body and the core and an earth bonding tag.

Ceiling diffusers shall be suitable for direct replacement of 600 x 600 ceiling tiles or an overall size relative to the selected neck size for fitting within a cut tile.

Branches serving individual diffusers shall be provided with a manual volume control damper supplied and fitted by the ductwork sub-contractor, in addition to the grille damper where supplied. The duct mounted volume control damper shall be located as close as possible (within 1 duct diameter) of the take-off with the main branch duct.

Where extract is required via ceiling mounted devices louver face diffusers shall be used. The diffusers shall be similar in construction and appearance to the supply diffusers.

The diffuser shall have fixed air control blades, central fixing screw with decorative cap and an opposed blade damper adjustable from the front face.

The plenum box shall be galvanised sheet metal with a rubber lip seal.

The plenum box shall have fixings for suspending the assembly from the ceiling slab.

The plenum boxes shall be suitable for side or top entry as required.

The diffuser face shall be extruded aluminium sections, natural anodised rear ancillaries in formed sheet steel, surfaces phosphate treated and stove-enamelled.

Supply and extract diffusers shall be at a distance from one another to prevent short circuiting. Supply diffusers shall be located away from one another to prevent two opposing air streams meeting and causing drafts, the individual velocities shall not be greater than 0.25 m/s.

- Performance:
 - Mixed flow applications: To BS EN 12238.
 - Sound power levels: To BS EN ISO 5135.

340 LAMINAR FLOW PANELS

Laminar flow panel diffusers shall be provided in operating theatres with a footprint that encompasses the operating site to produce a downward-displacement parallel-flow air distribution.

Diffusers, of all patterns, to operating theatres shall achieve the required velocity at the operating table position of between 0.2 and 0.3 metres per second, and achieve good air distribution throughout the remainder of the room. Particular care shall be taken to ensure that in a heating mode air discharge velocity overcomes the buoyancy of the air to achieve the required velocity at the operating table position.

The ventilation distribution arrangement must take priority over the layout of luminaires and pendants, etc.

350 TOILET SUPPLY AND EXTRACT VALVES

Extract with toilets, bathrooms and showers shall be via exhaust air disc valves. Each valve shall be constructed from sheet steel and provided with a stove-enamelled finish. The centre disc valve core shall be mounted on a threaded adjustable centre spindle complete with locking nut to provide air volume flow rate adjustment.

The centre disc assembly shall be mounted in a profiled outer ring complete with an edge seal and tamperproof sub-frame.

Generally each valve shall be installed within a cut tile. Each valve shall not require a plenum but shall be connected into a section of rigid ductwork before any flexible is used.

Each branch connecting to individual valves shall be provided with a manual volume control damper fitted as close to the upstream branch connection as possible.

360 DIFFUSERS, LINEAR

Linear diffusers shall be installed as shown on drawings.

They shall be made from aluminium extrusion, natural anodised.

Diffusers shall come complete with end caps and air control blades.

The diffusers shall have a rear mounted plenum box fitted with a side entry spigot and suspension brackets to hang the complete assembly from the ceiling.

The plenum box shall be fitted with a volume control damper adjustable from the diffuser face and be made from galvanised sheet steel.

- Performance:
 - Mixed flow applications: To BS EN 12238.
 - Sound power levels: To BS EN ISO 5135.
- Diffuser: Slot.
- Material: Aluminium.
 - Finish: Anodized.

370 DIFFUSERS, SWIRL

The swirl diffusers shall be adjustable in square or circular face plates with swirling horizontal discharge of supply air with high induction.

Diffusers shall consist of a pressed front face with radially angled air discharge sections incorporating adjustable directional air control blades.

Diffusers shall be complete with a plenum box with circular top or side entry spigots and volume control damper. The Plenum box shall be supplied with fixed hanging brackets.

The face plate shall be galvanised sheet steel with the surfaces pre-treated and powder coated white (RAL 9010).

The control blades shall be made from Polystyrol coloured black or white as Architects

specification.

The plenum box is made from galvanised sheet steel with a rubber lip seal.

The plenum box shall be galvanised sheet metal with a rubber lip seal.

The plenum box shall have fixings for suspending the assembly from the ceiling slab.

The plenum boxes shall be suitable for side or top entry.

Supply and extract diffusers shall be at a distance from one another to prevent short circuiting. Supply diffusers shall be located away from one another to prevent two opposing air streams meeting and causing drafts, the individual velocities shall not be greater than 0.25 m/s.

- Performance:
 - Mixed flow applications: To BS EN 12238.
 - Sound power levels: To BS EN ISO 5135.
- Material: Galvanized steel.
 - Finish: Epoxy resin powder/ hardener coating.

380 MEDICINEMA FLOOR DIFFUSERS

The Medicina shall be served by floor mounted displacement diffusers.

The diffusers shall be as Krantz DB-E.

390 GRILLES

Grilles shall be installed as shown on the drawings.

The grilles shall be made from extruded aluminium sections. The finish shall be as Architects RAL number. Grilles shall be selected for quiet operation.

Grilles, shall have corner mitres and rear perimeter sealing strip with profiled front blades.

Sub frames shall be used where required.

- Performance:
 - Mixed flow applications: To BS EN 12238.
 - Displacement flow applications: To BS EN 12239.
 - Sound power levels: To BS EN ISO 5135.

400 CEILING VENTING GRILLES (CVG)

Ceiling venting grilles shall be provided along the main distribution routes for medical gas and natural gas pipework.

Ceiling venting grilles shall be of similar construction and arrangement to the supply diffusers. The diffuser body only shall be provided for these items.

The minimum size of CVGs shall be 150 x 150mm.

410 PLENUM BOXES, CEILING OR WALL MOUNTED

Plenum boxes shall be made of 0.7mm Galvanised steel plenum.

Spigot construction shall be a top or side entry plenum option robustly fabricated plenums shall come complete with all necessary fixing angles for drop rod support.

- Duty: To match grille and diffuser.
- Configuration: Single plenum box or a series of plenum boxes butted together to form a continuous length.
- Construction: Sturdy and rigid with circular inlet spigots of 65 mm minimum length.
- Fixing: Incorporate means for fixing to, or suspending from, building or other construction.

EXECUTION

610 INSTALLATION

- General: Do not distort air terminal devices. Fix securely.
- Air leakage: Prevent. Seal joints with self adhesive foam strip or equivalent.
- Appearance: Finish visible edge joints neatly. Do not leave sharp edges and protruding screws.

620 FIXING CIRCULAR AND RECTANGULAR DIFFUSERS

- Method: As per manufacturers instructions and specification.

640 FIXING LINEAR AND SLOT DIFFUSERS

- Method: As per manufacturers instructions and specification.

650 FIXING FLOOR MOUNTED SWIRL DIFFUSERS

- General: Fit flush with finished floor.
- Method: As per manufacturers instructions and specification.

660 FIXING GRILLES

- Method: As per manufacturers instructions and specification.

670 OPERATION

- General: Fit so that moving parts operate correctly and removable cores can be taken out and replaced.
- High level and ceiling applications: On removable cores, provide safety wires with quick release ends.

680 BLANKING PLATES

- Location: Where needed to restrict projection of air flow from section of grille or diffuser.

APPENDIX A
SUPPORTING DOCUMENTATION

In order to carry out the design, the Sub-contractor shall require access at least to the documentation listed below.

The following information is, or shall be, available from the Contractor:-

1. Standard General Conditions and Preliminary Clauses
2. All ZBP Layout Drawings, Schematics, Specifications and Schedules
3. Nightingale Associates: Fire Strategy Drawings
4. Nightingale Associates: Building Plans
5. Nightingale Associates: Building Sections
6. Nightingale Associates: Wall Elevations
7. Nightingale Associates: Reflected ceiling plans
8. ZBP: Automatic Controls and Building Management System Specification :
ZBP-XX-XX-SP-660-401 to 406
9. ZBP: Fire Detection and Alarm Specification : ZBP-XX-XX-SP-572-214
10. ITPD Documentation and Appendices

Drawings for other specialist systems shall be developed by other Sub-contractors during the detailed design period and shall be made available by the Contractor

Alan, Colin

I have had another look at ZUTEC this morning and the chilled beam reference is different from that which we discussed yesterday (although that reference is in ZUTEC too).

The Parasol units have the ability for dew point control on the units as far as I can tell. For the critical/augmented control areas this may prove to be a better option than that being currently implemented.

I cannot check if the design called for this as the design info does not appear to be there

Regards

QUEEN ELIZABETH UNIVERSITY HOSPITAL

ADULTS WARD 6A - ROOM 1

Section 1 – Scope of Works

Annual Inspection of Critical Ventilation Systems

To carry out a compliance and performance inspection of all critical path ventilation systems in accordance with - Heating and Ventilation Systems - SHTM – Scottish Health Technical Memorandum 03-01: Specialised Ventilation for Healthcare Premises.

Part B: Operational management & Performance Verification.

This report is for Adults Ward 6A bedroom 1 located in the Queen Elizabeth University Hospital.

The validation of the rooms was carried out to record a baseline validation record for these rooms. This validation work followed post fitting of recirculation fans (Camfil Camcleaner 400 concealed fan units) located within the ceiling of the toilet of bedroom 1 on Ward 6A. The Camcleaner consists of a F7 pre-filter (bag) and a secondary H14 HEPA filter. See report details of fan settings, air volumes, room pressures and noise levels achieved while maintaining SHTM03-01 compliance.

QUEEN ELIZABETH UNIVERSITY HOSPITAL

ADULTS WARD 6A - ROOM 1

Section 2 – Definition of terms

Assessment of compliance with Health Building Note 26 and Scottish Health Technical Memorandum 03-01.

Poor

Air volumes and hence air-change rate is less than 75% of the design; room pressure differentials do not ensure a flow from clean to less clean areas. Supply or extract air diffusers are not clean. Pressure stabilisers not clean and/or not operating correctly. Visible faults in the fabric of the suite, doors unable to close completely, general air of neglect.

Action: Urgent management action required.

Average

Air volumes and room pressure differentials approximate to the original design values. Supply air diffusers clean but extracts visibly fouled most pressure stabilisers clean and operating correctly. Minor faults in the fabric and décor of the suite.

Action: Maintenance action required.

Good

Better than average.

Action: None.

QUEEN ELIZABETH UNIVERSITY HOSPITAL

ADULTS WARD 6A - ROOM 1

Section 3 - Executive Summary/Observations:

The evaluation of Adult's Ward 6A – Bed 1.

- 1) To make sure the noise levels in the bedroom and en suite were compliant with SHTM03-01 which are bedroom 35db(A) & en-suite 45db(A).
- 2) Noise levels and air volumes were measured to the various fan power levels on the recirculation unit in the en-suite (sped control setting level 1-6) Speed controller at setting 3 when all compliant and final values recorded within this report.

Adults Ward 6A – Room 1				
Fan Speed Setting	En-Suite dB(A) SHTM 45dB(A)	Bedroom dB(A) SHTM 35dB(A)	Air Volume l/s	*Increased scrub value for the en- suite (ACRs)
1	35.5	33.9	10	2.6
2	35.8	34.3	15	3.8
3	39.3	34.8	58	14.8
4	47.8	45.7	113	28.9
5	50.7	48.6	136	34.7
6	54.5	52.5	163	41.6

Comments: Speed 3 for the en-suite is SHTM03-01 compliant – Speed 3 is SHTM03-01 compliant for the bedroom noise levels.

RED = Final fan speed setting used

*These are the values for enhanced scrub up in the en-suite, the values noted above are an increase scrub up rate on top of the air change rate that the en-suite extract is achieving of 8.4 air changes per hour.

QUEEN ELIZABETH UNIVERSITY HOSPITAL

[IMG_20191112_101426317.jpg](#)

In response to the issues raised we can confirm:

(a) Ventilation

Extensive testing of the ward environment found no link between infections and the ward. We have introduced HEPA filters to the bedrooms and en-suites; the bedrooms have a positive pressure reading which means that the generally filtered air flows out rather than into the rooms. In addition, it should be noted that the high specification general filtration system for the entire hospital means that we have high levels of air filtration (87%) in place on all general areas.

The infection rates in the ward – as Cab sec confirmed – have reduced and the rates in the ward are on a par with other Scottish units.

Prophylaxis line (Scott Davidson)

(b) Water

What have we said about S-J K? No other infections have been linked to the water supply, despite testing.

(c) Showers

We answered these questions based on the concerns that families had raised with the clinical teams. We were aware that questions had been raised about the drainage and our response made clear that there were no issues with regards to the drainage system.

We had however previously briefed parents about dampness in some of the showers which was a result of sealant coming away from the walls. We also issued a media statement confirming this situation. Parents were kept fully informed about the action taken to address this issue.

(d) Leak in kitchen

The leak in the ward kitchen was inspected on close examination there was no evidence of saturated wall boarding, or of water getting behind, or below the flooring. All works were undertaken under RA conditions in line with the conditions that CP has outlined.

(e) IMT

It is true that there were a number of different views and hypotheses examined as part of our investigations into potential links between a number of infections and the environment. We also drew on national expertise, HPS, and the ward was re-opened on this basis of the extensive investigations by both the IMT and HPS, the results of which led to the agreement that the ward was safe to re-open to new patient admissions.

Subject: RE: Responses to Parents Question 6A

Tom

Have reused a previous statement along with supporting pictures that Ker had compiled, I think this tells the full story.

Ward 6A Entrance is -1pa to the lift hall with the doors closed, when the doors open the ward entrance becomes ambient as shown in Image 100307699 & 100316262.

Ward 6A Kitchen is -3 pa to the corridor with the door shut as it operationally should be as shown in image 1014266317 and does not fluctuate regardless of external door orientation, this is supported and expected by the evidence that the pressure cascade in the kitchen is under more negative pressure than the rest of the ward.

The narrative for the existing pressure regime in ward 6A is as follows :

All patient rooms are notionally positive to the corridor

The kitchen is negative to the corridor

The ward entrance to corridor is ambient to notionally negative depending on the door orientation which is extremely variable due to the traffic of people.

Subject: RE: Responses to Parents Question 6A

Importance: High

Mark, I have changed a few bits, but I am sure that we can put up a robust response to the assertion about the leak in the ward kitchen. This was viewed and all works were undertaken under RA conditions and on closer examination there was no evidence of saturated wall boarding, or of water getting behind, or below the flooring. In addition, it would perhaps not be unusual to detect fungal spores form a floor that has very regular footfall over it?

Cc: Inkster, Teresa (NHSmail) <[teresa.inkster](#)>

Subject: Responses to Parents Question 6A

Importance: High

Dear Prof McQueen and Prof White,

I hope you don't mind me writing to alert you to some objections I have to the answers that have been given to parents regarding 6A - which I saw on line today for the first time - as I consider them to contain inaccuracies based on my knowledge of the situation. In retrospect I think it would have been essential to discuss these answers with Dr Inkster who was Lead ICD and key microbiology Water expert in the hospital given her intimate knowledge of the history, results and expertise and experience in BMT environmental management over a decade at the Beatson.

Qus pertaining to ventilation

There is a difference between saying ventilation is "safe" (what does that mean?) and "meeting standards required for the patient cohort housed in the accommodation" . This is an important differential as it is only by meeting the standards /requirements that one can be assured that reasonable preventative measures are in place. Deviations from this are hard to compensate for – eg lack of positive pressure means unfiltered air readily accesses the room and is breathed by the patient posing a risk of fungal infection particularly (including Cryptococcus if it is in the air). This has been verified by air sampling results during Dr Hoods investigations.

The strain of Cryptococcus found in the patient that started the investigation has not been grown from the air. Confirmed at the Cryptococcus advisory group and John Hood

This ward is not designed to be a neutropenic facility, It was a clinical decision made by Infection Control to move to Ward 6A. however the interpretation of safe would be that this ward is safer than that of an equivalent standard general ward within the QEUH Campus, this is backed up by notional positive pressure barriers from rooms to corridor, mobile HEPPA scrubbers deployed throughout the ward corridors and bedrooms and standalone H13 air scrubbers installed in all en-suites which has evidentially reduced particulate rates.

It is a simple matter of fact that the rooms in 6A do NOT meet requirements for protective airborne isolation which is the infection threat to neutropenic high risk patients. Note , the same was true of 2A as evidenced by the external engineer reports and the requirement for a huge amount of remedial work that is required . This statement on 6A rooms is based on :

1. No positive pressure incorrect, notional positive pressure is established albeit is below the standard required for a Neutropenic cohort
2. 3 Ach instead of 10 correct
3. Chilled beams in situ Guidance does not stipulate that they should not be in situ, SHTM 03-01 gives specific guidance on the use of the chilled beams within Hospital and goes on to encourage the benefits they may bring (Section 2.38, SHTM 03-01 Part A, 2014). With regards to the internal air condition control, SHTM 03-01 states that humidity controls are not required within general wards in hospital areas (Section 1.24) but also suggests an air handling unit cooling coil control strategy which should be used when close control of

humidity is required of which has been implemented.

Guidance and legislation regarding the selection of active chilled beam HVAC system suitability for clinical environments will vary from country to country. Based on the Scottish Guidance (SHTM 03-01, 2014), it appears to be the case that Active Chilled beams are acceptable as the re-circulation is only present within the one space, and is not being transported across to different areas within the hospital as found in central plant re-circulation.

4. Air is not HEPA filtered at point of supply **Agreed this is the standard :**

Neutropenic patient ward temperature	10 ACH	+10 Pascals	H12 Filter	30 Noise rating	18-28
--------------------------------------	--------	-------------	------------	-----------------	-------

5. Air sampling has repeatedly found fungal counts above that expected for this patient cohort as well as bacterial counts

What is the Standard ? can she provide evidence of standards?

For this reason antifungal prophylaxis is the mainstay of risk mitigation at present.

Qus pertaining to water :

filters were put in place as a control measure due to a water supply that was contaminated **Who indicated that it was contaminated?** That is not made clear in the responses . The water that is describes as wholesome has high colony counts of Mycobacterium and fungi. This does not pose an issue to immune competent patients but certainly does for the cohort under discussion. At least one mycobacterial infection has clearly been linked to the hospital water by whole genome sequencing and my view is that it is not possible to state that the other 6A infections have no link to the hospital environment as has been stated in public statements, based on the epidemiology , environmental results and the nature of the organisms themselves. Teresa is best place to give a comprehensive review of the water risks. **Is there a separate standard for Neutropenic patient water supply out with Governments standards for hospital water supplies?** No other infections have been linked to the water supply, despite testing.

Qu 4 : re no problems with the showers

There was a problem with leakage of water under the floor with extensive mould under the flooring due to a poorly designed seal and the rigidity of the flooring material used . This required significant remedial work and a decant from the ward earlier this year. **Where welds in vinyl joints have broken the area has been inspected, repaired, or replaced under SCRIBE RA conditions.**

There was one incident in 4B of sewage effluent coming up a shower drain while a BMT patient was bathing . The patient went on to have an extremely rare environmental organism line infection. **Is there evidence that this infection is linked to the incident?** Unfortunately drains block, especially in Hospitals. Incidents such as this are quickly dealt with by the estates team as well as the domestic services staff in conjunction with infection control colleagues and clinical team.

QU 8 : Chilled Beams

chilled beam cleaning is in place to prevent build up of dust and particulate matter and organisms on the chilled beams. The fact that this is required as frequently as 6 weekly is an indication of a faulty system. **Guidance states that service intervals are 6 monthly to yearly and have only been shortened at the request of IC and estates endeavouring efforts to provide a high level service.** This level of service clean will be under review once regular surface testing is undertaken and reduced if possible to minimise disruption to the ward rooms.

These chilled beams should not be used in the immune compromised setting .**I agree in principle, but as previously stated this is not a guidance stipulation and as long as adequate control measures are implemented, dew point monitoring and source dehumidification of which now are, they meet the standard of the current guidance available.** And even when they are used in other settings the design is such that if they are installed correctly they should only be required to be cleaned 6

monthly to yearly. It is a major question of concern that these chilled beams accumulate dust and particulate matter at such a rate as to require 6 weekly cleaning. **Active chilled beams operate under induction therefore if they are requiring cleaning after 6 weeks then the cleaning process of the room must be called into question.**

Qu 30 : re leak into kitchen 27th September

Please find attached the SBAR I wrote regarding the leak and the results that Fungus was grown from a sample of the wet material. **This would not be unexpected given it is a floor that has regular footfall access by staff.** This was not a staff kitchen in the sense that it was where patient special feeds were stored and drinks prepared for parents and children. Please see photos of the water damage.

The risk from ANY water ingress into a BMT area is fungal propagation and spore dispersal followed by infections as well as collection of water borne organisms. Therefore the assurance given is incorrect. For the kitchen to have been made functional again all the wet material would need to have been removed with strict HAISCRIBE process in place . Was this carried out? **YES as standard SOP.** In addition, **no wall material was saturated, nor had any water permeated to the underside of the flooring, therefore all surfaces were intact.**

Qu Pertaining to IMT

There is no consideration given to the marked difference in opinions on the IMT or the fact that the chair of the IMT was replaced followed by her resignation linked to the way the IMT was handled. This is not an easy message to convey , however I think it is vital that there needs to be a level of acknowledgement regarding the fact that the main expert in infection control in the organisation had a view that was not taken on by the organisation, for this to be a truly transparent process. **Not for comment by me, any recommendations set by Terresa and her team were fully implemented to offset their original decision to move this patient group to a general ward.**

I am happy to discuss all of the above and while I do not doubt for a moment that every effort is being made to reduce infection risk, I believe that in order to build trust going forward a high level of accuracy in delineating risks is warranted.

Kind regards,

Christine

Ward 6A

Welcome to the Ward
We are making a change to our visiting times. This means:

- 1. We have no set visiting times
- 2. Please discuss with the person you are visiting and staff what it would be good for you to be here
- 3. We will always welcome and encourage your presence and support
- 4. Sometimes we may need to ask you to leave the ward temporarily to ensure privacy, safety, space and to rest in bed
- 5. If you have any questions, please just ask

What matters to you?

Background

The adult haemopoietic stem cell transplant service moved to the QEUH in May 2015, because of concerns that the planned level of support for acutely unwell patients on the GGH site would be insufficient to support such a high intensity speciality and would not meet the JACIE accreditation standards. The level of high intensity support provided at GGH prior to May 2015 was already far from ideal and any reduction would make it extremely difficult to maintain a safe service for patients. It was known in May 2013, at the time of the decision to move the BMTU to the new unit at the QEUH, that the corridor would not be HEPA filtered, but it was expected that the rooms provided would be of an acceptable standard for highly immunocompromised patients with appropriate HEPA filtration, room pressures and air exchange rates. Given the frequent requirement for support from HDU, ICU and other acute specialities it was agreed by the clinical team that this need should be prioritised when balanced against the lack of HEPA filtration in the corridor. Unfortunately, the unit had to return to the Beatson, West of Scotland Cancer Centre in July 2015 because of the identification of extremely poor air quality in the new transplant unit. This return was predicated on it being short-term with remedial works to improve the air quality in ward 4B, QEUH to acceptable levels. The BMT team agreed to work closely with the BWOSCC high acuity and QEUH teams to minimise the risk to critically unwell patients whilst at the BWOSCC.

Remedial Works Required

The GGC Infection control lead, Dr T Inkster, sought advice from Health Protection Scotland (HPS) about the changes required to ward 4B to establish the current standards for highly immunocompromised patients and review how they could be met. HPS in their document (SBAR_BMT_NHSGGC_PDF_version 52) detail what these should be. Some work has already been done and plans have been drawn up to achieve virtually all the other requirements. A feasibility analysis has been carried out and remedial action outlined which will improve the air quality in ward 4B, QEUH. However, this is still below the specifications set out in the HPS document

The major issues are

- Frequency of air exchange is below the recommended 10/hour
- Positive pressure in the room is below the recommended +10PA
- The corridor is not directly HEPA filtered although all air entering will be

It should be noted that in the above document HPS state that *“Ideally the corridor should also be HEPA filter supplied, however, this is normally only achieved in a purpose built unit and is less important if the rooms are appropriately ventilated and achieve positive pressure in comparison to the corridor.”*

Risks of Suboptimal Air Handling

The main risk poor air quality poses to patients is significant invasive fungal infection. It is impossible to quantify if there will be an increased risk incurred by moving back to the QEUH compared with the current provision at BWOSCC once the planned upgrade in air handling provision has been completed, given that there will be suboptimal air exchanges and no direct HEPA filtration of the corridor. Until the proposed changes have been made we cannot do air sampling or particle counts to look for fungal colonies. However, we can reduce the risk of invasive fungal infection by using well tolerated and effective anti fungal prophylaxis such as posaconazole. With the measures that have been taken already, and further measures that are being planned, the air quality is almost certainly going to be adequate to protect patients, albeit the specification does not fully meet HPS standards.

Risks of Remaining at the BWOSCC

The failure to completely meet the HPS standards at QEUH needs to be balanced against the following which are incurred whilst the service remains at the QEUH

- Lack of HDU/ITU at BWOSCC

- Requirement for early transfer to QEUEH to reduce risk of critically unwell patient at BWOSCC site. This means patients are being transferred to the QEUEH who would normally be managed on the ward.
- Exposure to an unprotected environment during transfer
- Potential for significant compromise in outcome due to lack of rapid access to these staff and facilities.
- On-going concern about ensuring optimal care for patients who have been transferred from the BWOSCC transplant unit to the QEUEH due to lack of on site BMT nursing, pharmacy and AHP expertise.
- Significant psychological effects on patients moved to QEUEH, who require to remain there for long periods of time, due to concerns about general stability of condition, but who could be managed in the BMTU if onsite at the QEUEH
- Difficulty in obtaining prompt medical and surgical opinions at BWOSCC, particularly OOH. Patients require transfer to QEUEH.
- Lack of beds at the BWOSCC delaying admissions and increasing risk of disease progression
- Single air handling plant at the BWOSCC which cannot be serviced and has failed several times in the last few months.
- The level of support available on-site will be inadequate for the unit to achieve JACIE accreditation.

Monitoring Regime

On conclusion of the works outlined in the feasibility report, monitoring of the environment will take place as follows:

- Air particle Count
- Active air sampling

Acceptable levels would be:

- Air particle Count < 1000
- Active air sampling fungal colonies < 1CFU/m³

UK Benchmarking

Of the 7 centres who responded to a local survey (across the UK), all are operating within varying environments as follows:

Hospital	HEPA filtered Rooms Y / N	HEPA filtered Corridors Y / N	Room Air Changes 10/hour Y / N (if different, please specify)	Room Pressure Positive 10Pa Y / N (if different, please specify)	Sealed Rooms (fixed ceilings etc) Y / N	Air Lock Entrance to Ward Y / N	Is Air Pressure Monitoring System Alarmed Y / N	Is there a "Back-up" air handling plant for Wards Or Separate plant for each room	Rooms with anteroom at negative pressure for infectious BMT patients Y / N (Please state approx. Pa)	Do you operate a programme of Environmental Monitoring (Particle Counting / Microbial air sampling etc – please state acceptable limits)	HDU / ICU on-site	Comment
QEUH Proposal	Y	N (approx. 4 AC/hr with positive pressure to external corridors + wards)	N Approx. 6AC/hr	N (approx. 2.3-8 Pa)	Y	Y	Y Audible alarm outside each room	Y Independent (back-up) AHU unit available if primary unit fails	Y (Available via adjacent Renal Ward)	Y Monthly programme of Microbial Air Sampling and Particle Monitoring	Y	
UCLH	Y	N	Y	Y	Y	N	No, pressure gauge on wall	No	-10KPa on separate floor	Micro sampling of all wards (contact plates etc) led by infection control. HEPA qualified annually by external company.	ITU + HDU	

St Bartholomews (Barts Health)	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Back up	Yes	Done by infection control. No SOP that I'm aware of.	ICU on-site for BMT patients. Other ICU'/HDU' for cardiac patients	Whole floor is HEPA filtered (Brand new facility – last year)
Nottingham University Hospital	Y	N	Y	Y Runs at <10	N Suspended ceilings	N	N But is checked every morning by ward staff and then alarm raised if out of range.	Y Back up generators Monitored by estates dept	N/Y Negative pressure can be achieved by leaving the bathroom door open. ?Pa	Y NUH Infection control dept coordinates this – air particle sampling and micro sampling done. Also water sampling showers and sinks. Throughout ward. Results go through to ward Manager.	Critical Care Unit on-site	
KCH	Y	Y	Y	Y	Y	Some	Y	N	Y	No. Rooms verified on opening. Regular HEPA filter replacement.	HDU + ICU	
ANON	Y	No. Each room positive to corridor	Y	Y	Y	Y	Yes, local and central	Separate AHU for each patient room. Main Ward on separate system.	Yes, 15Pa in anteroom and 10Pa in patient room.	No. Rooms verified on opening. Regular HEPA filter replacement.	ICU (ITU)	
Royal Devon & Exeter	Y	N	Y	Y	Y	N	N	N	Y	Y	ITU (+HDU)	
Leeds Adult	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	ICU + HDU	

N.B QEUH is based on the specification once the works outlined in the recent feasibility study are completed.

Conclusions

On this basis, it is our belief that the current proposals will ensure an adequate solution to providing a safe environment for patients and compare favourably to the physical environment available at BWoSCC:

	Current BWoSC C	Proposed QEUH
HEPA filtered Rooms Y / N	Y	Y
HEPA filtered Corridors Y / N	Y	N (HEPA filtered air supplied to rooms – cascaded to corridor then external corridor under positive pressure differential).
Room Air Changes 10/hour Y / N	Y	Approx 6 AC/hr
Room Pressure Positive 10Pa Y / N	Y	Approx 2.3 – 8 Pa
Sealed Rooms(fixed ceilings etc) Y / N	Y	Y
Air Lock Entrance to Ward Y / N	Y	Y
Is Air Pressure Monitoring System Alarmed Y / N	N	Y
Back-up plan Y / N	Y	Y
Rooms with anteroom at negative pressure for infectious BMT patients Y / N	Y	Y
Programme of Environmental Monitoring Y / N	Y	Y
ICU /HDU	N	Y

Queen Elizabeth University Hospital (NHSGGC) Bone Marrow Transplant Unit**Situation**

NHS Greater Glasgow and Clyde (NHSGGC) initially requested support from Health Protection Scotland (HPS) in 2015 in the review of their Bone Marrow Transplant Unit within Queen Elizabeth University Hospital (QEUEH) prior to transfer of patients from the Beatson Oncology Centre (WOSBOC). This review focussed mainly on the ventilation and provision of a safe environment for the care of these patients within the QEUEH. HPS liaised with HFS and support has continued since the initial request.

Background	The decision to transfer the care of bone marrow transplant patients from the Beatson Oncology Unit to the QEUH was made in June 2013. Construction of the QEUH was well established at this point and therefore the unit was not purpose built. When the new hospital opened patients transferred to ward 4b from the Beatson Oncology unit. Concern was raised following environmental and air sampling yielded high particulate counts and fungal spore growth. On identification of these results the patients were relocated back to the WOSBOC as a temporary measure whilst remedial work was undertaken in ward 4b. Currently the patients remain in the WOSBOC whilst works have been ongoing in ward 4B in an attempt to make the unit compliant. It is noted that there is no current UK guidance on BMT isolation rooms. General ventilation guidance is contained within SHTM 03-01 (Parts A and B) and SHPN 04-01 Supplement 01. Additionally, an SBAR was produced in May 2015 which provided GGC with recommendations to allow the provision of a protective environment for patients within the bone marrow transplant unit. The SBAR focussed primarily on the adult BMT transfer to ward 4B was produced by HPS/HFS in December 2015 (Appendix 1). Whilst NHSGGC has continued to work towards these recommendations it is noted that the solution proposed does not meet the guidance nor does it seek to address all the recommendations in the SBAR(2015). As a result HFS cannot comment on the effectiveness of the measures intended to be put in place. NHSGGC are working towards transfer of the patients from the BOSWOC to ward 4B by early 2018. A staged approach to repatriation of the BOSWOC BMT patients back to ward 4B has been proposed. This includes transfer of existing medical patients to other areas within the hospital, ventilation within the area turned back on once patients have vacated the area and external validation and commissioning of the unit will be undertaken. Once this has been completed and agreed with facilities, IPCT and management haemato-oncology patients from the South Glasgow are will occupy ward 4b for a period of 6 months will microbiological monitoring is undertaken. HPS have been requested to provide support relating to initial monitoring of the environment prior to transfer and during the first six months of the transfer to allow early identification of airborne fungal spore risks. A rapid literature review relating to microbiological risks was undertaken (Appendix 2) and support sought from Peter Hoffman (Public Health England)
-------------------	--

Assessment	The recommendations outlined in the SBAR (2015) relating to ventilation included: To allow the provision of a protective environment for patients within the bone marrow transplant unit (Ward 4B) • The rooms must be positively pressured at 10 pa • ALL air entering the room must be via the HEPA filter • The HEPA filter should as a minimum be E12 (H13) and located within the supply air diffuser • The rooms must be sealed and no air which has not passed via the HEPA filter should access the room • A strict protocol which minimises the length of time the door is opened and reduces air entry via an open door is required. • There must be a continuous pressure monitoring system for each room which alarms and gives an early indication of a pressure drop within the room • Bedroom Air changes of 10 ACH must be achieved • The walls and ceilings within the rooms and ensuite must be sealed. • All room services must be sealed • All service access hatches within the bedrooms/ensuite must be sealed NHSGGC have confirmed that the rooms meet 10Pa however fall short on air changes at 6 AC/hr instead of the recommended 10 AC/hr. Air changes dilute the microbial content of the room from what is already dispersed within the room. The main focus from protection of the immune-compromised patient is to ensure protection is provided from outdoor contamination via hepa filtration. The integrity of the hepa filter requires to be insitu checked with particles to ensure its efficiency and correct fitting. It is an engineering recommendation that the design philosophy as outlined in SHPN 04-01 Supplement 1 is followed as far as reasonably practicable and that the supply and extract branches to each suite are fitted with spring close gas tight dampers to allow individual suites to be closed for maintenance or cleaning. It should be noted that BSRIA are recommending that air permeability should be between 2.5-1.0m³/hr/m² at 50Pa and given the limitations of the existing solution, it may be prudent for NHS GGC to consider this. Extract ventilation ductwork should be separate and terminate as described in SHPN 04 Supplement 01.
-------------------	--

	<u>Ventilation rates:</u> Validation of the entire system should be as detailed in SHTM 03-01 part A and verification of the entire system should be as outlined in SHTM 03-01 part B. The frequency of verification should be at least annually, or more frequently if issues arise. <u>Sampling:</u> There are two ways of sampling: • Active air sampling • Passive air sampling Active air sampling involves using the air sampler and monitoring all patient rooms and corridor on the same day and sampling a high volume of air of at least 1 cubic metre of air from each room. There is no requirement for rooms to be empty during sampling as the testing is to identify fungi not bacteria Passive air sampling involves using settle plates in every room and allowed to remain in situ for a period of approximately 5-6 hours. Settle plates will sample fungal spores relatively inefficiently but can sample over a far longer time than active air samplers and so capture isolated contamination dispersion events that active sampling is likely to miss. The medium used should be selective medium which only allows the growth of fungi. (e.g Sabaraud's with appropriate selective supplements), Sampling should take place in an adjacent unprotected environment simultaneously to those within the rooms. Fungal levels in the outdoor environment (i.e. the challenge to any system of patient protection) will vary over time. A finding of low fungal counts in the protected may just be the result of a low challenge level. This sampling strategy allows the determination of a contamination ratio of the protected environment versus unprotected environment. A combined approach of both passive and active air sampling undertaken in parallel utilising media which selects fungi only , using the same medium, is the preferred method for commissioning and monitoring purposes, with both methods being undertaken simultaneously including an external unprotected control sample. Samples taken at weekly intervals for a period of 4-6 weeks at varying times should provide sufficient information on the integrity of the ventilation system with consideration being given to a follow up one month later. Thereafter sampling should return to the agreed boards protocol. Microbiological sampling is used as a validation of
--	---

	engineering and engineering controls and should only be done after the engineering parameters have been assured as adequate. Annual validation of engineering is important and must be undertaken. Results: Fungal growth does not require to be speciated. If controls are in place the optimal level should be zero growth. The presence of any fungal spores on active sampling should prompt a review. The following strategy per cubic metre of air sampled is proposed • Zero growth = optimal • Single digit = review room air supply, confirm direction of outward air passage at multiple gaps in the room's integrity, examine room for areas of dampness or fungal growth. Investigate possible errors in sampling technique and resample • Double digits and above = indication of a serious problem. Urgent investigation and clinical consideration of fungal prophylaxis It is worth noting that a zero result, whilst optimal, does not always assure engineering efficacy as it may be reflective of no circulating fungal spores at the time of testing. <u>Lighting and power:</u> Luminaires to be recessed into a solid ceiling and be (minimum) IP44 with clear access strategy for maintenance including gear and lamp replacement. Any power, trunking or other services penetrations into the space must be sealed. <u>Water:</u> The water systems should be to SHTM 04-01 and free of any waterborne pathogens at the point of use. <u>Contingency:</u> As it is proposed that only one air handling unit serves the BMT isolation rooms, planned shut downs or unplanned events (such as motor failures or power failures) require to be addressed. The result of these shutdowns may mean that patients may need to be relocated. It is suggested that contingency plans include:- • AHU complete failure for prolonged period • AHU complete failure for short duration • AHU maintenance (air related – filters, fans, cleaning,
--	---

	etc) • AHU maintenance (water related - cleaning, testing, inspecting) • Cleaning or deep cleaning of rooms following occupation. • If the AHU does not have a duty/standby arrangement, spare supply fans are sourced and stored locally to the AHU. • If ALL the ductwork is not fire rated, what happens in the event of a fire scenario. It may also be prudent to have contingency plans for local power failure and in the event of pathogens found in the local water supplies to the BMT isolation facilities
Microbiological monitoring Recommendation	• Both active and passive air sampling should be undertaken in parallel • Sampling should be undertaken weekly at varying times for a period of 4 -6 weeks and a follow up one month later • All patient rooms within 4b should be included in each sample period • An external adjacent unprotected area should be identified and passive sampling undertaken in parallel with protected (BMT unit rooms) sampling • Standard sample plates should be used which are selective for fungi and that inhibit bacterial growth • Any fungal colonies identified require to be counted but not speciated • As the medium used are selective for fungi and not bacteria, the rooms do not require to be vacated during the sampling period. • Passive sampling/settle plates should be left insitu for 4-6 hours approximately ensuring the plates do not dry out. • Active sampling volume should be approx 1,000 litres per room. • The air sampler should be placed on a clean trolley or stand • The medium for both passive and active sampling should be the same • Results should be interpreted: • Zero growth = optimal • Single digit = review room air supply, confirm direction of outward air passage at multiple gaps in the room's integrity, examine room for areas of dampness or fungal growth. Investigate possible errors in sampling technique and resample

	• Double digits and above = indication of a serious problem. Urgent investigation and clinical consideration of fungal prophylaxis • Annual validation of ventilation should be undertaken in line with the agreed protocol, based on selected components of SHTM 03-01 part B. • Once completion of commission monitoring as outlined above the normal monitoring protocol endorsed by NHSGGC should be resumed

Alberti et al. Relationship between environmental fungal contamination and the incidence of invasive aspergillosis in haematology patients. <i>Journal of Hospital Infection</i> (2001) 48:198-206	Prospective surveillance	BMT unit and 2 haematology wards France	Bi-monthly air and surface fungal sampling of patient rooms (some with HEPA filters and LAF systems) as well as communal sites (corridors etc) carried out over a 4-year period. Invasive nosocomial aspergillosis infections were monitored over the same period. Patterns of fungal contamination were comparable in the three wards, with a gradient ranging from high levels in common sites and conventional rooms (up to 6 cfu/m ³) to a virtual absence in rooms equipped with HEPA filters and LAF systems. Using a regression model, a significant relationship was found between	This study emphasizes the utility of environmental surveillance. The authors recommend that pressure measurement should be regularly checked , as a decreased air pressure within the ward can result in a fungal contamination from adjacent sites. Monitoring of air fungal contamination is also recommended based on the significant relationship observed between incidence of invasive aspergillosis and air contamination with <i>Aspergillus</i> and non- <i>Aspergillus</i> species. The authors also recommend environmental surface monitoring based on the relationship they observed between fungal contamination of surfaces and invasive aspergillus infections.

Reference	Study type	Setting	Summary	Conclusions/recommendations
			the incidence of invasive nosocomial aspergillosis and the degree of fungal contamination of air and surfaces in conventional patient rooms (not equipped with HEPA) and common sites. The study found that peaks of air contamination by <i>Aspergillus</i> ≥ 2 cfu/m ³ had a determining role in the relationship between environment contamination and the occurrence of invasive aspergillosis.	
Bellanger et al. Fungal aerocontamination exposure risk for patients in 3 successive locations of a paediatric hematology unit department: influence of air equipment and building structure	Prospective surveillance	Paediatric haematology department France	Monthly air fungal sampling carried out of patient rooms and weekly air fungal sampling of corridors over a ten-year period, during which time the unit was relocated twice: from a building without a	Based on their results, the authors suggest a threshold alert of 8 CFU/m³ for unit corridor aerocontamination.

Reference	Study type	Setting	Summary	Conclusions/recommendations
on air quality. <i>American Journal of Infection Control</i> (2017) 45: e109-e113.			filtration system (B1) to a renovated building with low air pressure (B2) to a new building with high air pressure and HEPA filters. Multivariate statistical analysis showed that B2 was approximately 2.9 times more contaminated by mould than B3 ($P = .004$), whereas B1 was approximately 1.8 times more contaminated than B3 ($P = .32$). The study also found that contamination of air in corridors was important. Whenever opportunistic fungi are >8 CFU/m ³ in unit corridors, the risk of fungal aerocontamination in rooms is multiplied by 4.	
Reboux et al. A 10-year survey of fungal of	Prospective surveillance	Haematology units	Study retrospectively assessed the	A trigger threshold of 40 cfu/m ³ in main corridors is suggested – the authors state

Reference	Study type	Setting	Summary	Conclusions/recommendations
aerocontamination in hospital corridors: a reliable sentinel to predict fungal exposure risk? <i>Journal of Hospital Infection</i> (2014) 87: 34-40	e		contribution of fungal aerocontamination measurement in haematology corridors and main hospital corridors as a sentinel to assess fungal exposure and risk of invasive mould infections over a ten year period. Air samples were taken every week in the same locations in haematology corridors and main hospital corridors. All fungal species were identified. The Haematology and Hospital Hygiene Departments were alerted systematically whenever a peak of opportunistic species was detected and corrective action was planned. 12 peaks of <i>Aspergillus fumigatus</i> (>40 CFU/m³) were	that at this level it was possible to keep the staff alert without warning them too often. A trigger level of >1cfu/m³ was set in haematology corridors. While the study found that while monitoring did not prevent all invasive aspergillosis cases, the authors felt that the absence of surveillance could reduce staff vigilance and consequently increase the risk of invasive fungal infection.

Reference	Study type	Setting	Summary	Conclusions/recommendations
			observed in the main hospital corridors, and <i>A. fumigatus</i> contamination was detected up to six times per year in the haematology corridors. Peaks in the main corridors were thought to be associated with outdoor works (building, excavation and construction), indoor works (removal of false ceilings) and turning on the heating system. It was not possible to establish a link between invasive aspergillosis diagnosis and recent <i>A. fumigatus</i> peaks in the main or haematology corridors.

Gonçalves Meneguetti et al. Assessment of microbiological air quality in hemato-oncology units and its relationship with the occurrence of invasive fungal infections: an integrative review. <i>Revista da Sociedade Brasileira de Medicina Tropical</i> (2013) 46(4):391-396	Review	Haematology/Oncology units	Integrative review that included 13 primary studies. The results of the studies suggest that suggesting that HEPA filtering of the ambient air in hemato-oncology units can prevent the incidence of invasive fungal infections. Currently, there is no consensus about the maximum allowable count of fungi in the air, which complicates filtration monitoring, including filter maintenance and replacement.	There is a requirement for consensus on maximum allowable count of fungi in air.
Morris et al. Sampling of <i>Aspergillus</i> spores in air. <i>Journal of Hospital Infection</i> (2000) 44: 81-92	Review	General healthcare	The review outlines many of the physical and environmental parameters that influence meaningful air sampling for <i>Aspergillus</i> and recommends a simple procedure that has been tried and tested in many aspergillosis outbreaks.	Interpretation of air sampling data and recommendations A single air sample will often underestimate the fungal contamination in the air: multiple air sampling has to be performed No strict numerical guidelines are available which are appropriate for assessing whether the contamination in a particular location is acceptable or not but the following threshold

Reference	Study type	Setting	Summary	Conclusions/recommendations
				levels have been recorded: • Outdoor air: total fungal count: 10^3 to 10^5 CFU/m³ • Aspergillus: 0.2–3.5 conidia/m³ Note: seasonal variation recognised • HEPA filtered air (> 95% efficiency and > 10 air changes per hour): <0.1 CFU/m³ • No air filtration: 5.0 conidia/m³ • Construction/defective ventilation: 2.3–5.9 conidia/m³ If total fungal count exceeds 1.0 CFU/m³ on several occasions the air systems or procedural practice in patient areas requires intensive evaluation.
Rupp et al, Routine sampling of air for fungi does not predict risk of invasive aspergillosis in immunocompromised patients. <i>Journal of Hospital Infection</i> (2008) 68: 270–282	Letter to the editor	Haematopoietic stem cell transplant Unit	In response to an outbreak of invasive aspergillosis, the authors implemented weekly fungal sampling in the unit, which continued for a 7 year period. <i>Aspergillus</i> spp. were recovered from 163 (16.7%) of the air samples. Of air cultures yielding <i>Aspergillus</i> spp., the quantitative results	Due to the fact that air sampling did not appear to be helpful in predicting the risk of invasive aspergillosis, as well as the fact that it takes 5–7 days for results of air samples making it too late to intervene to prevent exposure, the authors discontinued routine air sampling for mould. Instead, emphasis is now placed on

Reference	Study type	Setting	Summary	Conclusions/recommendations
			ranged from 1.8 cfu/m³ to 28.3 cfu/m³. Other non-<i>Aspergillus</i> spp. of fungi, predominantly <i>Penicillium</i> spp., <i>Cladosporium</i> spp. and <i>Alternaria</i> spp., were detected in 567 of the air cultures (58%). Analysis revealed that routine weekly quantitative air cultures did not appear to be helpful in predicting the risk of development of invasive aspergillosis in the subsequent 14-day and 28-day time periods.	maintenance of the ventilation system and the physical integrity of the HSCT unit, as well as environmental cleanliness.

Guidance

Reference	Key recommendations /information
Chang et al. Consensus guidelines for implementation of quality processes to prevent invasive fungal disease and enhanced surveillance measures during hospital building works. <i>Internal Medicine Journal</i> (2014) 44: 1389-1397	• Employ targeted air sampling prior to the commissioning of a new ward or air-handing system • Consider using targeted environmental sampling as a measure of enhanced surveillance during any hospital building works. • Consider using targeted environmental sampling to facilitate outbreak investigations. Air sampling: A written, defined, standardised, multidisciplinary protocol for sample collection and culturing is required in institutions where targeted air sampling is performed. Analysis and interpretation of results should use scientifically determined or anticipatory baseline values for comparison. Expected actions, based on the results obtained, should also be defined. Unfortunately, the

Reference	Key recommendations /information
	sensitivity, specificity and threshold values are unclear, and there are no uniform air quality standards. Microbiological sampling of air, water and inanimate surfaces is hampered by the variability in collection protocols, analysis and interpretation. Settle plates (sedimentation or depositional methods) are not recommended for sampling fungal spores as spores can remain suspended in the air indefinitely. There are no universally accepted standards or guidelines for the interpretation of fungal spore or colony counts collected in response to an outbreak. Fungal spore levels vary over time and with other factors, such as ambient light and humidity. An exposure level of <5 CFU/m³ of <i>Aspergillus</i> spp. in protective isolation areas and <0.1 CFU/m³ in HEPA-filtered environments, with limits of 15 CFU/m³ for gross colony counts of all fungal organisms, is recommended.
Dykewicz. Hospital infection control in hematopoietic stem cell transplant recipients. <i>Emerging Infectious Diseases</i> (2001) 7(2): 263-267	• Some experts suggest that hospitals routinely sample air, ceiling tiles, ventilation ducts and filters to test for molds, especially when construction or renovation occurs near or around the rooms of immunocompromised patients or when clinical surveillance demonstrates a possible increase in mold (e.g. aspergillosis) cases [CIII: This is an optional intervention because evidence is insufficient to support a recommendation or evidence for efficacy might not outweigh adverse effects/This is evidence from authorities' opinions based on clinical experience, descriptive studies, or reports of expert committees]. • In the absence of a nosocomial outbreak, HSCT units need not perform routine fungal cultures of devices and dust in the rooms of HSCT recipients and candidates undergoing conditioning therapy [DIII: Indicates that moderate evidence for lack of efficacy or adverse outcome supports against the intervention/ This is evidence from authorities' opinions based on clinical experience, descriptive studies, or reports of expert committees]
Sehulster LM et al.Guidelines for environmental infection control in health-care facilities.	Microbiologic sampling of air in health-care facilities remains controversial because of currently unresolved technical limitations and the need for substantial laboratory support.

Reference	Key recommendations /information
Recommendations from CDC and the Healthcare Infection Control Practices Advisory Committee (HICPAC). Chicago IL; American Society for Healthcare Engineering/American Hospital Association; 2004	Infection-control professionals, laboratorians, and engineers should determine if microbiologic and/or particle sampling is warranted and assess proposed methods for sampling. The most significant technical limitation of air sampling for airborne fungal agents is the lack of standards linking fungal spore levels with infection rates. Despite this limitation, several health-care institutions have opted to use microbiologic sampling when construction projects are anticipated and/or underway in efforts to assess the safety of the environment for immunocompromised patients. Microbiologic air sampling should be limited to assays for airborne fungi; of those, the thermotolerant fungi (i.e., those capable of growing at 35°C–37°C) are of particular concern because of their pathogenicity in immunocompromised hosts. Use of selective media (e.g., Sabouraud dextrose agar and inhibitory mold agar) helps with the initial identification of recovered organisms. Box 6. Unresolved issues associated with microbiologic air sampling • Lack of standards linking fungal spore levels with infection rates (i.e., no safe level of exposure) • Lack of standard protocols for testing (e.g., sampling intervals, number of samples, sampling locations) • Need for substantial laboratory support • Culture issues (e.g., false negatives, insensitivity, lag time between sampling and recording the results) • New, complex polymerase chain reaction (PCR) analytical methods • Unknown incubation period for <i>Aspergillus</i> spp. infection • Variability of sampler readings • Sensitivity of the sampler used (i.e., the volumes of air sampled) • Lack of details in the literature about describing sampling circumstances (e.g., unoccupied rooms vs. ongoing activities in rooms, expected fungal concentrations, and rate of outdoor air penetration) • Lack of correlation between fungal species and strains from the environment and clinical specimens • Confounding variables with high-risk patients (e.g., visitors and time spent outside of protective

Reference	Key recommendations /information
	environment [PE] without respiratory protection) • Need for determination of ideal temperature for incubating fungal cultures (95°F [35°C] is the most commonly used temperature) Settle plates, because they rely on gravity during sampling, tend to select for larger particles and lack sensitivity for respirable particles (e.g., individual fungal spores), especially in highly-filtered environments. Therefore, they are considered impractical for general use. Settle plates, however, may detect fungi aerosolized during medical procedures (e.g., during wound dressing changes). The use of slit or sieve impactor samplers capable of collecting large volumes of air in short periods of time are needed to detect low numbers of fungal spores in highly filtered areas. In some outbreaks, aspergillosis cases have occurred when fungal spore concentrations in PE ambient air ranged as low as 0.9–2.2 colony-forming units per cubic meter (CFU/m³) of air. On the basis of the expected spore counts in the ambient air and the performance parameters of various types of volumetric air samplers, investigators of a recent aspergillosis outbreak have suggested that an air volume of at least 1000 L (1 m³) should be considered when sampling highly filtered areas. Investigators have also suggested limits of 15 CFU/m³ for gross colony counts of fungal organisms and <0.1 CFU/m³ for <i>Aspergillus fumigatus</i> and other potentially opportunistic fungi in heavily filtered areas (≥12 ACH and filtration of ≥99.97% efficiency). No correlation of these values with the incidence of health-care– associated fungal infection rates has been reported.
National Guidelines for the Prevention of Nosocomial Invasive Aspergillosis During Construction/Renovation Work. National Disease Surveillance Centre, Dublin 2002	Contains an Appendix outlining a recommended air sampling method, drawn from Morris et al's 2000 review. No strict numerical guidelines are available, which are appropriate for assessing whether the contamination in a particular location is acceptable or not but the following threshold levels have been recorded: • Outdoor air (Note: seasonal variation recognised): • Total fungal count: 10³ to 10⁵ CFU/m³, • <i>Aspergillus</i>: 0.2-3.5 conidia/m³

Reference	Key recommendations /information
	• HEPA filtered air (>95% efficiency and >10 air changes per hour): < 0.1 CFU/m³ • No air filtration: 5.0 conidia/m³ • Construction/defective ventilation: 2.3-5.9 conidia/m³ If total fungal count exceeds 1.0 CFU/m³ on several occasions the air systems or procedural practice in patent areas requires intensive evaluation.
Ruiz-Camps et al. Guidelines for the prevention of invasive mould diseases caused by filamentous fungi by the Spanish Society of Infectious Diseases and Clinical Microbiology (SEIMIC). Clinical Microbiology and Infection (2011) 17(supplement 2): 1-24	• What is the usual spore concentration in hospital air? Studies must be carried out in each centre [unprotected hospital air] to determine the normal concentration and detect significant increases. Counts above 25 CFU/m³ can be considered to be very high. (Level II) • When should microbiological determinations of air be performed? It is advisable to carry out environmental cultures when required by current legislation and when there are cases of IFI [invasive fungal infection] caused by aerial fungi or when refurbishment and maintenance works are being carried out. However, some experts recommend carrying out cultures on a regular basis to verify the proper operation of the facility, both in operating theatres and in protected rooms. (Level IA) • What is the acceptable concentration of fungi (CFU) in protected air? The limit of CFU/m³ of air is 0.5, which means, as a maximum, it is possible to detect one colony of filamentous fungi in a sample of 2 m³ of air. (Level IC) • What is the acceptable concentration of fungi (CFU) in unprotected hospital air? Figures vary according to the study consulted. Under normal conditions, this should be below 25 CFU/m³. (Level II) • Do routine microbiological surveillance cultures have any additional value? They may be useful to determine the integrity of the filters of protected areas, although filter maintenance is more important. They may be helpful to determine the presence of unexpected contamination foci in centres that do not have adequate installations. They make it possible to have historical measurements to use for comparison purposes. (Level II)
Tomblyn et al. Guidelines for preventing infectious complications among hematopoietic cell transplantation recipients: a global	• Routine microbiologic air sampling for fungal spores in HCT units is not recommended, as its role has not been established (DIII). However, during a suspected outbreak, there may be a role for microbiologic air

Reference	Key recommendations /information
perspective. <i>Biol Blood Marrow Transplant</i> (2009) 15: 1143-1238 Yokoe et al. Infection prevention and control in health-care facilities in which hematopoietic cell transplant patients are treated. <i>Bone Marrow Transplantation</i> (2009) 44: 495-507	sampling in patient care areas (CIII). If microbiologic air sampling is performed as part of an outbreak investigation, sample volumes of at least 1000L may achieve a higher degree of sensitivity than smaller samples.

Ventilation Review Appendix K information discussed at meeting of 10/11/10

Noted that the review was on the preliminary design of 5 departments produced for GMP costing purposes and that flexibility in design is possible moving into the detail design phase. **Issues having wider implications and major effect on the energy consumption are highlighted.**

1.	Ventilation review	ZBP issues	Nightingale issues	Relevant drawing	Response/ discussion points	Action
2.	General and information requests					
2.1.	Resend as file corrupt	ZBP-XX--PL-534-301_02 ZBP-XX--PL-534-302_02 ZBP-XX--PL-524-304_02				
2.2.		ZBP-XX--PL-524-050_03				
2.3.		ZBP-XX--PL-524-023_01				
2.4.		ZBP-XX--PL-524-004_03				
2.5.		ZBP-XX--PL-524-005_02				
2.6.		ZBP-XX--PL-524-015_04				
2.7.		ZBP-XX--PL-524-007_02				
2.8.		ZBP-XX--PL-524-028_02				
3.	Zoning comments generally					
3.1.	AHUs serving ward areas A and C	Where there are areas within wards which are unlikely to be used at night , can ventilation be reduced to these areas- e.g. dayrooms, treatment rooms offices, school rooms etc?		ZBP-XX-03-PL-524-303_02		
3.2.	41 AHU 22 2 nd floor NCH admin areas	This only serves office and daytime use area – is there any potential for mixed mode here or for air flow related to internal temperature only? Is it full fresh air or can recirc be introduced here?			Minimal fresh air therefore no point in recirculation. Openable windows not possible at this stage	
3.3.	Isolation AHUs	Is there any form of control			Discussed and to be referred to	BE/ZBP

		so that when these areas are not in use, they shut down or go onto low volume and uncontrolled temperatures (indications and local control to bring areas up to "room ready" may be required)			Board – operational policy needed - note that room ready indication would be needed in any case for +ve,-ve operation and in case unit has a fault or is shut down for maintenance.		
3.4.	Circulation and storage	How are these heated/ventilated?			(please confirm response)	BE/ZBP	
3.5.	31AHU26 Endoscopy	Configuration for this unit? Is all extract through PHX?			Please confirm – this unit was either not on schematic or on a drawing we could not open	BE/ZBP	
3.6.	IT hubs	Do these have supplementary cooling and if so, how is this achieved?			Confirmed that this is from central chilled water. Further development needed here as 1. Chillers may be required all year to serve these distributed areas – free cooling via air only to be considered for majority of year 2. Need to combine with IT meeting to discuss target PUE and means of air distribution plus potential for natural cooling (possibly with chiller back up)	BE/ZBP/EL/NHSGGC	
3.7.	Control generally	Where AHUS serve rooms with varying heat gain, how is individual room temperature control achieved?			Needs further discussion – to be reviewed with controls	BE/ZBP/EL	
3.8.	33AHU01 renal? area		Staff base and store			BE/NA	

			if reversed would give staff view out				
3.9.	As above		Planning around the reception/plant/waiting / changing creates large internal office – could any re-planning here for example relocating the staff change create a better staff environment and reduced lighting energy consumption?			BE/NA	
3.10.	31AHU29 staff areas	There appears to be a mix of 24 hour and 12 hour areas here – how is the unit sub zoned?	The staff change areas have access to daylight via the atrium, whereas various offices and 4 person workstation area do not - could any re-planning here for example relocating the staff change create a better staff environment and reduced lighting energy consumption?		Consider sub zoning – need to develop with board more accurate and detailed occupancy patterns to establish the most efficient way of serving this and the remainder of the theatre areas.	BE/ZBP	
3.11.		Local override controls could be useful to overnight room			General issue where there are isolated 24 hour areas within	BE/ZBP	

		– to top up heating when rest of unit is on setback for example which time out automatically			zones which are otherwise 24 hour – to be considered on full review of detailed design	
3.12.	31AHU17 and all other theatre plant and recovery areas	How are these controlled and is there a setback facility to each?			Set back facility confirmed to all theatres but noted that extended hours and 24 operation to emergency theatre likely. Recovery – 2 areas – detailed discussion on usage patterns needed to establish if one area can be set back.	
3.13.	31AHU27	Is this a day case areas – it incorporates the lift lobby areas - is it 12 hour only or 24 hour and again what if any are set back arrangements ?			Please confirm – need to review lobbies generally.	BE/ZBP/EL/NHSGGC
3.14.	31AHU30	This appears to be a general clean area ancillary to theatres – presumably positive pressure area. – is there set back/ variable volume to this area and how is it controlled? Is there heat recovery to the extract?			Heat recovery confirmed in schematics. Set back confirmed as possible – see 3.12 above	
3.15.	41AHU25 and wards generally with regen kitchens	What is likely heat gain to the area, what happens to the extract and is there opportunity here for heat reclaim?		ZBP-XX-03-PL-524-305_02	Regeneration kitchens need further consideration and detail design. To be reviewed once equipment type more developed. Confirmed that heat reclaim from extract is planned. Consider serving regeneration	BE/ZBP/EL/NHSGGC

					kitchens from dedicated plant with no cooling	
3.16.	41AHU25 – children’s wards generally	There are quite large daytime only areas from grid R13.1 west – these could be mixed mode.			Sealed building decision now taken. Sub zoning of daytime only areas to be considered – where these are at the end of distribution, dampers would be possible to VSDs. Detailed patterns of use to be discussed,	BE/ZBP/EL/NHSGGC
3.17.	All Adult ward plant	Public core areas are served from ward plant – is it necessary for this area to have cooled air and would simple vent plant with heat recovery be more economical?		ZBP-XX-03-PL-524-306,7_02	These areas are circulation and waiting only. Extract and simple local vent to waiting rooms would appear to be sufficient. BE/ZBP to confirm	BE/ZBP/EL/NHSGGC
3.18.		As comment 3.1				
3.19.	121AHU07 122AHU07 CORE AREAS PLANT	What is confirmation of units and can these be simple vent without cooling?			As 3.17 above	BE/ZBP
3.20.	Kitchen 31AHU61	How is heat recovered from chilled areas – opportunity to preheat supply air – need to discuss refrigerant heat reclaim options for this area		ZBP-XX-03-PL-524-300_02	This area is understood to be under development. The chilled production areas would be capable of heat recovery and the heat used for adjacent areas	BE/ZBP
3.21.			I assume main kitchen layout still in production?		The kitchen layout is still in development. The schematics show full conditioned air to the kitchen. It was suggested that the canopies should be untempered filtered air only and conditioned air used for background ventilation to kitchen only	BE/ZBP

3.22.	22AHU25	Is this a basic vent unit as serving storage only? I would suggest demand based time out control to maintenance area heating as this is likely to be intermittent and entire area can then be heated to say 16C only with no cooling			To be confirmed	BE/ZBP
4.	Ventilation schematics					
4.1.	General comments based on 21AHU01	Is carbon filtration to be fitted and permanently active? This will significantly increase energy use and maintenance cost of plant even when there is no need of carbon filtration. Could a bypass be arranged so that carbon filter is only used when necessary?		ZBP XX XX SC 524 701_02	This needs discussion at main design meeting – it was acknowledged by all that the carbon filtration will have a high pressure drop and therefore high impact on the fan energy consumption. It was agreed that a whole life cost should be developed for a sample AHU looking at the life cost in energy, maintenance and capital cost terms for a range of options including carbon filtration – options for this include omission of carbon filtration or a bypass arrangement. The results to be contained in brief report for presentation to board.	BE/ZBP by next meeting
4.2.		I assume heat recovery device is a thermal wheel – please confirm, is there a control mode such that that when free cooling is possible, heat is not			To be developed further in controls discussion	BE/ZBP

		recovered from exhaust?				
4.3.		Motor drive - belt or direct? Belted and running to both motors or one – what is relative motor frame size for these options? Have integrated variable speed motors been considered?			The options for direct and belt driven to be considered in WLC terms as 4.1 above.	
4.4.		What are filter ratings and clean/dirty settings?			To be confirmed and reviewed.	BE/ZBP/EL
4.5.		How is VSD configured?			To be confirmed and reviewed.	BE/ZBP/EL
4.6.		Are MD1 and 2 for maintenance only? If so are these necessary as motorised – isolation plates decrease airstream resistance – for discussion			To be confirmed and reviewed.	BE/ZBP/EL
4.7.		VSDs- performance spec to consider efficiency and losses – what is best and worst on market and suppliers to be chosen on WLC			VSD choice and effect of best and worst to be part of WLC review	BE/ZBP/EL
4.8.		Have we now confirmed that the motors and fans are not to be oversized?			Discussion took place on the means of achieving the ER's requirement for 25% spare capacity. Option A Over sizing fans and motors is least favoured option as the fan efficiency is likely to be poor for the life of the plant. Option B Space for additional plant and	BE/ZBP by next meeting

					ductwork is possible but the additional plant and riser space is significant and the cost and complication of retrofitting additional plant is substantial Option C A further option which is favoured on carbon saving grounds is providing plant sized at 25% lower face velocity – i.e 2.0m/s as opposed to 2.5m/s. This is a modest increase in plant room and riser size compared to option B and has the further advantage of saving in fan power for the life of the plant until any upgrading is required. When upgrading is required, the fans would be changed to the higher duty which is a relatively simple and low cost operation. Option C is therefore recommended – to be confirmed by WLC cost exercise and to wider design team	
4.9.		Are all motors HEMs			Confirmed – to be checked through detail design.	
4.10.		What is face velocity? (payback 2.5 to 2.0 is <3 years typically)			See discussion in 4.8 above – to be part of WLC exercise	
4.11.		Fan efficiency- see design guide			Choice of DD or belt drive and the motor in or out of airstream	

Comment [SCL final1]: The choice of drive mechanism and motor type will also yield considerable energy-savings potential. Additional energy savings of 2 to 5 W/ft² (21.6 to 54 W/m²) may be achieved with the substitution of high-efficiency motors for standard-efficiency motors. The choice to use fans with motors outside the primary air stream will save 1.0 to 1.5 w/ft². (10.7 to 16.15 W/m²) due to motor inefficiency, but removal of the motor from the air stream by using belt-driven fans with lower mechanical efficiencies will reduce the energy savings. High-efficiency motors have an inefficiency of 6% to 8%, whereas belt-drive systems have inefficiencies of 4% to 6%. The use of special direct-drive fans with motors outside the air stream (bifurcated fan housings) may result in higher system effects and lower total efficiency.

		Discussion needed on whether proximity of HR will allow fan to develop full performance			to be considered as part of WLC exercise as above		
4.12.		Coli design – compare pressure drops between manufacturers which can vary considerably for the same performance			To be further developed in detail design.	BE/ZBP/EL	
4.13.		Overall what is target SFP _v ?			Calculate typical for WLC exercise – discussed that SFP overall would need to be calculated for Building Warrant but that this is likely to be an average value as AHU SFP likely to be higher than extract.	BE/ZBP by next meeting	
4.14.		See comments above re zoning- is clinical staff office 12 or 24 hour?			All zoning to be re-reviewed as detail design progressed	BE/ZBP	
4.15.		Reheat arrangements – can room temp sensors reschedule off coil to prevent wasteful reheat?			To be further considered during controls review	BE/ZBP/EL	
4.16.		Are cooling and main reheat coils in ahu interlocked to prevent simultaneous operation?			To be further considered during controls review	BE/ZBP/EL	
4.17.		What are economics for heat reclaim from dirty extract?			This required further discussion at wider team level. There are considerable economies to be gained both in space, capital cost, carbon and running cost terms by omitting separate dirty extract provision. HTM03-01	BE/ZBP	

					states that "Extract ventilation is required in sanitary facilities, dirty utilities and rooms where odorous but non-toxic fumes are likely; this is to ensure air movement into the space. A single fan/motor unit should be provided to meet this need. There is no healthcare requirement to provide a separate foul/dirty extract system." Whilst it is appreciated that the equivalent SHTM does not have this provision, it was agreed that as an update in the near future of the Scottish standard may follow the precedent set by the English standard, it is worth seeking derogation of the requirement for separate twin dirty extract. This will enable all heat from extract to be recovered	
4.18.		Is supplementary heating or cooling proposed in spaces served?			It was agreed that this was hard to follow across the various drawings issued to date. A marked up set of drawings is to be prepared which demonstrates the control	BE/ZBP by next meeting

					heating cooling and ventilation strategy to each space – this can be colour coded and initially cover the 5 designed departments		
4.19.	21AHU08-17 critical care isolation	As comments above 4.1 4.3 4.4-4.13 4.16 4.18	ZBP XX XX SC 524 707_02		See comments above		
4.20.		What are economics for heat reclaim from extract?			See comments above		
4.21.		Is fan to be sized for future HEPA – if so, how does this affect efficiency and would it be better to accept a future fan change if very inefficient selection likely?			Fan change suggested as a strategy – to be agreed with wider design team	BE/ZBP/EL	
4.22.		See also zoning comments re set back – room ready could be added to nurse panel			See comments in 3.3 above	BE/ZBP	
4.23.	Acute assessment ward 21 AHU24	As comments above 4.1 4.3 4.4-4.13 4.15-18 (single motor noted)		ZBP XX XX SC 524 714_02	See comments above	BE/ZBP	
4.24.		Are DE and CE volumes reversed?			To be confirmed and clarified	BE/ZBP	
4.25.	Adult A&E 21AHU28 and 29	What is the criteria for thermal wheel versus PHX and what is the impact in loss/gain of efficiency?			To be part of the WLC exercise	BE/ZBP by next meeting	

Comment [SCL final2]: Synchronous belts are stretch-free and can achieve higher efficiency than V-belts due to lower hysteresis, lower friction losses, and truly synchronous operation (no slip; no creep). The lower flexing losses result from the small thickness of the belt between the teeth. The absence of speed losses (slip and creep) is due to the positive mating of the teeth of the belt with the teeth of the sprockets. Because of these lower losses the synchronous belts have not only higher peak efficiency than V-belts, but also the efficiency curve is flatter. Synchronous belts require toothed pulleys (sprockets), which are more expensive than V-belt pulleys. In a retrofit application, the additional investment required is the cost of the sprockets, plus the extra cost of the belts and of the installation. In the cost-effectiveness calculations it is assumed that those extra costs fall in the range \$8-16/hp. This price variation is strongly dependent on the rating of the belt drive, with the large drives requiring a smaller price premium per horsepower. The sprockets typically cost 1.5-2 times the cost of belts (the second and third purchased at future times and thus discounted) and one set of sprockets. Additionally, it is assumed that there is an average 5% efficiency improvement and that the belt will last 24,000 operating hours. Synchronous belts provide slip-free synchronous operation, have a long lifetime, and can operate in wet and oily environments. Their operation can be noisy at high speed and their main weakness is the lack of capability to absorb shock loads.

4.26.		Is single temperature detection sufficient within spaces ?			Needs further discussion – to be reviewed with controls	BE/ZBP/EL

Proposal to Relocate Adult haemopoietic Stem Cell Transplant Service From Beatson West of Scotland Cancer Centre to Queen Elizabeth University Hospital

1. Introduction

This paper outlines the background to the current situation within BMT services. The paper details the enabling works and monitoring processes that have been undertaken since the last paper to the Acute Services Committee in March 2017.

The paper recommends that the service relocates from the Beatson West of Scotland Cancer Centre to Ward 4B at the Queen Elizabeth Hospital as originally intended.

The Acute Services Committee is asked to endorse this recommendation.

2. Background

NHS Greater Glasgow and Clyde is commissioned by National Services Division to provide all adult allogeneic donor stem cell transplantation for the population of Scotland. The national service covers both stem cell donation from family members and unrelated donors. The SLA value in 2016/17 was £7,904,092 for 70 transplants. This is proposed to increase to £8,114,359 for 73 in 2017/18, with on-going increases in activity predicted.

In 2013, a decision was taken to move the BMT service from wards B8/B9 at the BWoSCC to the new QEUH. This was to address concerns that the planned level of support for acutely unwell patients on the Gartnavel General Hospital (GGH) site would be insufficient for such a high intensity speciality as BMT and would not meet the JACIE accreditation standards. The move also allowed for an increase of beds from 19 to 24 to support the agreed increase in the national transplant programme.

Capital funding of £1million was invested to support enabling works to 4B, such as upgrade air filtration plant, and the BMT service moved to the QEUH in May 2015.

Following the identification of air quality issues in the new transplant unit, the service was, however, returned to B8/9, BWoSCC in July 2015. This return was predicated on it being short-term, with further remedial works to be undertaken to improve the air quality in ward 4B QEUH to acceptable levels. Remedial works were completed by October 2015 and at this time the service began to make plans to move back to QEUH.

The Infection Control Team raised concerns regarding the specification of works that had been completed and requested input from Health Protection Scotland (HPS) at this time. Following the receipt of recommendations from HPS with regard to the required specification, the Infection Control Team advised that the specification did not meet the required environmental standards for a BMT Unit and therefore, they were unable to support return to the QEUH. The BMT service has remained at BWoSCC since this time. The

clinical team have on-going concern about delivering a safe and sustainable service from the BWoSCC site, given high demand for critical care support and support from other medical and surgical specialties for transplant patients.

In the autumn of 2016, a further feasibility study commenced into potential options utilising retained estate on the QEUH site. A report was produced in January 2017 and a multi professional option appraisal was undertaken. From this, the conclusion drawn was that further options on the QEUH site at this stage were neither technically, clinically nor financially viable.

The two options that remained for consideration were remaining in the existing location on B8/9 in BWoSCC or relocation to 4B at QEUH as per the current specification. Following a detailed option appraisal process, involving clinical teams, infection control and Health Protection Scotland the Acute Services Committee at their meeting in March, 2017 approved a monitoring period of the ward 4B environment be undertaken to reassess the environmental suitability of transferring the BMT service to QEUH.

3. Process

Enabling works were performed from October to December 2017 to include new solid ceilings in the en-suite areas, replacement of filters, HEPA filtration unit installed in drug preparation area, heating controls rewired to eliminate control issues and door control devices fitted to improve the pressure differentials. Validations and permeability testing were performed and confirmed as satisfactory.

In October 2017, a robust process for assessing the effectiveness of this work to provide an appropriate protective environment for patients undergoing transplantation was developed in consultation with Health Protection Scotland, Health Facilities Scotland and expert external advice. An SBAR was produced and the subsequent monitoring and validation has been completed according to these recommendations.

4. Air Monitoring

Weekly monitoring started in January 2018 for an agreed period of 6 weeks, with non-transplant haemato-oncology patients in the ward to ensure testing in real-world conditions. The air sampling results were as expected with counts generally <1000 given the unit specification and are deemed satisfactory for the intended purpose of the unit.

Active air sampling has revealed low fungal counts including *Aspergillus* and *Mucor* – this is to be expected given the lack of a HEPA filtered corridor. These counts were mainly in the corridor area rather than the HEPA filtered rooms. In view of this, keeping doors closed to rooms is essential.

Moving forward we would plan to institute monthly air sampling with the same parameters as those used in the Beatson BMT unit i.e. particle counts <1000. Fungal colonies would trigger a review by the infection control doctor.

5. Water Monitoring

Water testing for *Legionella* and *Pseudomonas* is negative. Regular testing will be undertaken. There is a water contamination incident in QEUH and RHC with several different

Gram negative environmental bacteria and fungi. There have been no patient cases in ward 4B linked to water contamination. The source has been traced to the taps and showerheads and possibly contaminated pipework. The same taps and showerheads are in 4B therefore, the same control measures will be employed. Shower heads will be changed to disposable. All outlets in 4B have filters which is a short term control measure. Expert opinion is being sought with regards to long term control measures which will likely include different taps and chemical dosing. Fungi can be difficult to eradicate from water therefore the likely recommendation will be point of use filters in the long term.

6. Meeting to Review Monitoring Results

All relevant parties including representation from HPS, HFS, NSS met in March 2018 and agreed that testing to date was satisfactory and if confirmed in a final round of testing, the group would recommend the transplant unit to return to the QEUH. This has now been completed with recent results consistent with previous monitoring results.

7. Contingency Planning

There is an agreed contingency plan utilising mobile HEPA filter units in the event of a ventilation failure.

The costs associated with this are £100,000 to include 25 mobile units, 2 industrial supply units and critical spares.

8. Summary and Recommendation

The enabling works and subsequent validation and monitoring have been completed according to the SBAR recommendations and confirms the environment in ward 4B is appropriate for transplant patients. It is therefore recommended that the BMT unit return to the QEUH as soon as practicable with proposed date of 16th June 2018.

The Acute Services Committee is asked to endorse the recommendation that the BMT service moves back to QEUH in June 2018.

Gram Negative Bacteraemia (GNB) and Mycobacterium *chelonae* Incident Management Team

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status/Update
23/08/19	John Mallon will get new stickers to be made up which will easily identify water samples requiring testing in relation to this incident.	John Mallon	Ongoing	
23/08/19	IPCT to see if any surveillance has been carried out in the past regarding paediatrics which the IPCT can pick up on	IPCT	Ongoing	
23/08/19	Standard Operating Procedure is to be written to outline requirements if a patient is moved out with Ward 6A.	IPCT	Ongoing	
23/08/19	Biocide is to be introduced to the chilled beams water.	Estates	Ongoing	
23/08/19	Revised SOP regarding the cleaning of chilled beams is to be sent to Dr Inkster	Estates	Ongoing	
23/08/19	Public toilets out with ward 6A including the disabled toilet are to be closed.	Estates	Ongoing	
23/08/19	Increase the dosing of chlorine dioxide to 0.7 PPM	Estates	Ongoing	
23/08/19	HEPA filtration units are to be fitted to en-suite bathrooms in Ward 6A.	Estates	Ongoing	
23/08/19	Timeline of when the boiler lost pressure and increased condensation is being compiled by Estates and will be mapped against patient timeline	Estates	Ongoing	
23/08/19	Unfiltered water from Ward 6A DSR is to be tested along with water from DSR in PICU	Estates	Ongoing	
23/08/19	Point of use filter to be fitted to DSR within PICU	Estates	Ongoing	
23/08/19	Briefing communication for staff and patients/family are to be created	Lorraine Dick Jenn Rodger	Ongoing	
23/08/19	A holding statement for the press is to be written up	Lorraine Dick	Ongoing	
23/08/19	Peer review of ward 6A by someone from Great Ormond Street or Leeds Children Hospital is to be arranged	Dr Emilia Crighton	Ongoing	

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status/Update
23/08/19	Walk round to Ward 6A by HPS is to be organised.	Annette Rankin	Ongoing	
23/08/19	Air testing is to be carried out within the Room 6 en-suite as new HEPA filter unit has been installed.	Estates	Ongoing	
23/08/2019	William Hunter is to investigate the details of the new scrubbing machine that Emma Somerville reported on being used within Ward 6A.	William Hunter	Ongoing	
23/08/2019	Replace sink and IPS panel within Ward 6A DSR to enable a different tap to be fitted so a point of use filter can be installed.	Colin Purdon	Ongoing	
23/08/19	Access to filtered water domestics can use while the sink in Ward 6A DSR is not being used.	Estates	Ongoing	
23/08/2019	Check that Ward 2A/2B RHC refurbishment are not installing similar sinks within the DSR where point of use filters cannot be used.	Colin Purdon	Ongoing	
14/08/19	Stefan Morton is to carry out hand hygiene training for staff within Ward 6A.	Stefan Morton	Ongoing	Extra teaching has been planned for the next few weeks
14/08/19	Push fittings are to be replaced with mechanical fittings for the chilled beams.(4 replacement connectors in each room) This will be carried out as soon as possible.	Colin Purdon	Ongoing	
08/08/19	Environmental samples of the chilled beams are to be taken within Ward 6A and compared with samples taken of chilled beams in a spate area out with ward 6A.	Teresa Inkster	Ongoing	
08/08/19	Clinicians have requested 2 additional beds be made available within Ward 4B, BMT, QEUH to accommodate immunocompromised patients.	Dr Emelia Crighton	Ongoing	Dr Crighton will see if there is two additional beds for patients within Ward 4B, QEUH
08/08/19	An option appraisal meeting is to be held to set out possible solutions if Ward 6A is to relocate.	Kevin Hill	Ongoing	
08/08/19	Point of use filters to be fitted to taps within Clinic 2, RHC. Some sensor taps may need replaced in order to fit filters.	Colin Purdon	Ongoing	Estates haven't identified a suitable tap to replace sensor taps which are unable to be fitted with point of use filters. An alternative tap is to be procured.

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status/Update
03/07/19	Alan Gallagher is to create a detailed plan on what measures will be taken to minimise disruption to patients and clinical service when shock dosing treatment is implemented.	Alan Gallagher Teresa Inkster	Ongoing	Water experts were contacted on 13th August. They have requested for more extensive testing around the campus to ascertain how extensive mycobacteria is throughout the hospital. Dr Inkster has asked to see a report on what has been done regarding the water dosing, including water samples that have been taken. Water group are meeting on Friday 16th August to discuss further. Estates have concerns regarding the problems which occur when carrying our shock dosing to Ward 6A as a whole tower will need shut down to implement this. Increase of dosing has been carried out from 0.2 to 0.5 PPM on 5th July 2019
25/06/19	Annette Rankin is to obtain a list of all positive M.Chelonae cases in Scotland. She will also do a report of all gram negative bacteramias and compare them between hospitals. About the nature of the organisms	Annette Rankin	Ongoing	Annette will send an SBAR relating to this to Dr Inkster tomorrow morning. Last two cases will be added onto her report. AR will send out next week w/b 19/8

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status
COMPLETED				
08/08/19	Estates to explore if it is possible to add in Chlorine Dioxide to the sealed water supply within the chilled beams.	Tom Steele	Complete	Estates have spoken to the chilled beams service provider who have experienced dosing the system with biocides. They require to know what has been found in the system so they know what biocides are required but will need to make sure there is no chemical reaction. Adding more chemicals to the chilled beams may cause other problems if there are any future leaks from them.
08/08/19	Lorraine Dick is to set up a meeting to discuss how future correspondence can be given to patients/staff.	Lorraine Dick	Ongoing	Lorraine is meeting with Kevin Hill at the end of this week to discuss. Patients/parents are given a weekly update with staff given written communication so they can refer to if questioned.
08/08/19	John Mallon and facilities are to meet to discuss future labelling of samples.	John Mallon	Ongoing	Colin spoke to DMA not enough room on bottles to put location on it so they put codes on bottle and create a sheet with a list of codes. They will now send the list of codes. Getting lot of water samples through find easy way what to test water for. Look for a sticker or an analysis so that they know what the lab have to test for/target. DMA to have specific form or have a specific sticker for water testing regarding this incident. John Mallon will get office staff to come up with new stickers in which DMA can use for future water testing.
08/08/19	Sink within Nuclear medicine used to dispose of isotopes is to be investigated.	Colin Purdon	Ongoing	A partition has been placed between the two sinks. Colin Purdon will try and procure a tap that a point of use filter can be fitted to this sink. Been some resistant from department but this has since been resolved.
08/08/19	Updated timeline of all patients involved regarding this incident is to be sent out to the group. Dr Inkster will send Gillian Bowskill of a 2 nd possible case to be added onto the time	Gillian Bowskill	Complete	GB to send updated timeline electronically to clinicians. Sent out this morning.

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status
14/08/19	William Hunter is to find out if the scrubbing machines used in Ward 6A use Actichlor solution within them	William Hunter	Ongoing	William looked at scrubbing machine there was a slight residue of water after. Solution has been changed to Actichlor after finding out it was filled with unfiltered water with a neutral detergent solution. Emma Sommerville reported that there now seems to be different scrubbing machine being used within the ward which William Hunter will investigate.
14/08/19	Tom Steele is to send Dr Inkster the Data sheet regarding the a sample HEPA filtration unit which can be deployed within patients en-suites.	Tom Steele	Ongoing	This has been installed into Room 6, Ward 6A.
14/08/19	Toilet seat covers are to be fitted to patient en-suites	Colin Purdon	23/08/19	Complete
03/07/19	ARJO bath is to be removed from Ward 6A and cap the water outlet to the bath once approval has come from Anne Harkness	Darryl Connor	14/08/19	It was agreed that the water pipes will be capped so minimal disruption to ward. Scribe has been prepared and awaiting the go ahead for the decommission for this.
08/08/19	Look into a device that could gather all the condensation from chilled beams and be collected centrally within the ward	Colin Purdon	N/A	This has been taken off the action plan as there should be no condensation coming from the chilled beams.
08/08/19	Mechanical lock to be fitted to public toilet at the entrance of Ward 6A.	Colin Purdon	14/08/19	Complete
08/08/19	Alan Gallagher is to circulate his action plan regarding how estate/facilities issues are managed within Ward 6A.	Alan Gallagher	14/08/19	Complete
08/08/19	List of patient that are planned to come into Ward 6A is to be obtained.	Brenda Gibson	14/08/19	Complete
01/08/19	Water samples from the chilled beams are to be taken	Darryl Conner	08/08/19	Complete
01/08/19	The new algorithm regarding the functionality of the chilled beams is to be implemented	Colin Purdon	08/08/19	Complete
01/08/19	Chilled beams are to be cleaned every 6 weeks instead of 3 months. Estates will link in with SCN to ascertain availability of patient rooms	Darryl Conner	08/08/19	Complete

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status
01/08/19	Dr Inkster will send the en-suite room numbers from where the positive air samples originated room so estates can look into possible sources.	Teresa Inkster	08/08/19	Complete – no obvious source
01/08/19	The introduction of Ciprofloxacin is to be given to patients if clinicians are in agreement?	Brenda Gibson	08/08/19	Complete
01/08/19	Peer audit of patient central line care is to be carried out by the practice development educator in conjunction with the Infection Control Team.	Jenn Rodgers	08/08/19	Complete
01/08/19	Gillian Bowskill and Sandra Devine will complete HIORT to be sent to Dr Inkster then onto HPS	Gillian Bowskill Sandra Devine	08/08/19	Complete
01/08/19	Agreement on general communication that can be shared between patient's/parents and NHS staff.	Teresa Inkster Kevin Hill Lorraine Dick	08/08/19	Complete
01/08/19	Dr Kennedy will send out his epidemiology findings comparing infection rates from the old Yorkhill site to the new RHC site.	Iain Kennedy	08/0/819	Complete – this will be added to the agenda for the next IMT as Dr Kennedy was not present.
03/07/19	Sink within DSR may be getting a retrofitted filter attached to it. Currently speak to manufacturer	Darryl Conner	N/A	This was taken off action list as no Point of Use filter can be found that would fit this sink. Ongoing struggling to find a filter that is suitable to fit. This is not do able take off action plan.

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status
03/07/19	Drain cleaning is to be carried out in Nuclear Medicine and MRI where ward 6A patients have been visiting.	Darryl Conner	08/08/19	Complete - Work in progress, sink used in Nuclear medicine radioactive waste is put down the sink. Darryl will need to check drainage. Complete.
03/07/19	All point of use filters removed for routine replacement are to be labelled and kept until water results have been returned	Darryl Conner	01/8/19	Complete
03/07/19	Every 2 weeks water testing is to be carried out for half of Ward 6A then carried out for the other half	Darryl Conner	01/08/19	Complete - for water testing for all cold taps every 2 weeks
03/07/19	Karen Connelly will contact Anne Harkness to seek approval for the removal of the ARJO bath.	Karen Connelly	01/08/19	Complete
03/07/19	Tap within unused prep room in ward 6A is to be replaced as no point of use filter can be fitted.	Darryl Conner	01/08/19	Tap has been replaced but water is now hitting the back of the sink. The sink has been put out of use.
03/07/19	Dr Inkster & Prof Gibson are to meet up with Steve Russell to discuss the current development of ward 2A/2B, RHC	Teresa Inkster Brenda Gibson	01/08/19	Dr Inkster & Prof Gibson have met with Steve Russell and Hazel McIntyre from Capitol planning and signed off the design for Ward 2A/2B.
25/06/19	Patient recently transferred to Edinburgh Children's Hospital is to be included in the Gram Negative patient timeline	Susie Dodd	25/06/19	Complete
25/06/19	Dr Iain Kennedy is to contact Scottish water to obtain samples of water being sent to QEUH campus to be tested within our own labs. Samples have been obtained from properties beside the QEUH and also from the Gartnavel site.	Dr Iain Kennedy	01/07/19	Complete
25/06/19	Darryl and Gael to meet up to confirm when the best time to fit point of use filters to areas where Ward 6A patients are likely to attend i.e. Theatres	Darryl Conner Gael Rolls	01/07/19	Complete

Date Agreed Action	Action	Responsible Person/s	Completion Date	Status
25/06/19	Modification to the aluminium sphigots within CHWB in Theatres & CDU will be undertaken. Unable to carry out due to technicalities so it was agreed that bottle brushing the drains will be carried out instead.	Darryl Conner	01/07/2019	Complete
25/06/19	Increase dosing of chlorine dioxide is to be undertaken to the water supply	Colin Purdon	01/07/19	Complete
25/06/19	Additional hand hygiene step involving gelling of hands after being washed is to be introduced.	Gael Roll	01/07/19	Complete
25/06/19	Water samples are to be taken from chilled beams from Ward 6A	Darryl Conner	01/07/19	Complete
25/06/19	A log of when and where water leaks have happened due to the chilled beams is to be completed.	Darryl Conner	01/07/19	Complete
25/06/19	Air sampling for bacteria within Ward 6A is to be carried out while water is running into a CHWB to see if aerolisation is present	Dr Teresa Inkster	01/07/19	Complete
25/06/19	Kevin Hill & Dr Chris Deighan will take forward at Executive level regarding incidence of similar cases of Gram Negative Bacteraemia within similar units in with the rest of the UK.	Kevin Hill Dr Chris Deighan	01/07/19	Complete
25/06/19	Sandra Devine spoke to Dr Jennifer Armstrong about informing Edinburgh Royal Infirmary about testing their water supply before opening. She has requested that this should be carried out in a national forum and asked HPS for clarity. HPS informed the group that ventilation and water issues have been discussed at length between HPS and HFS	Sandra Devine	01/07/19	Complete
19/6/19	Compile Timeline of M.chelonae case (SJK)	Susie Dodd	20/06/19	Complete
19/6/19	Apply POUFs to theatre outlets	Colin Purdon	21/06/19	Complete
19/6/19	Check water cooler removed from 6A staff room	Colin Purdon	20/06/19	Complete
19/6/19	Carry out water testing in ward 6A pre and post POUFs (incl showers) and in theatres pre POUF application.	Colin Purdon	24/06/19	Complete

Date Agreed	Action	Responsible Person/s	Completion Date	Status
19/6/19	Water testing to be undertaken on outlets identified from timeline which currently have no filters.	Colin Purdon	24/06/19	Complete
19/06/19	Obtain Information from PAL to ensure that POUF are effective against Mycobacteria.	Colin Puirdon	24/06/19	Complete
19/6/19	Compile report of water sampling results across RHC site to establish extent of M.chelonae within water supply.	Colin Purdon	24/06/19	Complete
19/6/19	Situation update report for clinical staff	Dr Chaudhury	20/06/19	Complete
19/6/19	Prepare holding press statement	Mark Dell/Dr Inkster	20/06/19	Complete
19/6/19	Provide email update to senior management teams	Dr Teresa Inkster	19/06/19	Complete

Title

PMI/General/126 - A&C Hospitals - Omission of Carbon Filters

Description

The Board advise that they do not want carbon filters installed to the A&C Hospitals. (Cross reference EW 036). The Board wish to understand the cost saving of a) not fitting carbon filters to Air Handling Units which allow for the Carbon Filters to be retro-fitted and b) omission of carbon filters completely and fitting of air handling units which do not require carbon filters nor have the infrastructure for retro-fitting carbon filters.

EFFICACY OF HIGH-EFFICIENCY PARTICULATE AIR FILTRATION IN PREVENTING ASPERGILLOSIS IN IMMUNOCOMPROMISED PATIENTS WITH HEMATOLOGIC MALIGNANCIES

Theresa Hahn, PhD; K. Michael Cummings, PhD; Arthur M. Michalek, PhD; Brian J. Lipman, MD; Brahm H. Segal, MD; Philip L. McCarthy, Jr., MD

ABSTRACT

OBJECTIVES: To describe and investigate the cause of an outbreak of 10 cases of nosocomial invasive infection with *Aspergillus flavus* in a hematologic oncology patient care unit.

DESIGN: A retrospective cohort study.

SETTING: The hematologic oncology unit of a comprehensive cancer center.

PATIENTS: Ninety-one patients admitted to the hematologic oncology service between January 1 and December 31, 1992, for 4 or more consecutive days were included in the study.

RESULTS: Ten (18%) of 55 patients admitted from July to December 1992 were diagnosed as having invasive aspergillosis compared with 0 (0%) of 36 patients admitted from January to June 1992 to the same patient care units. Patient characteristics, mortality rate, autopsy rate, and admitting location did not change significantly during the course of the year to result in a sudden

increase in the number of aspergillosis cases. The source of the outbreak was the high counts of *Aspergillus* conidia determined from air sampling in the non-bone marrow transplant wing during the outbreak. After high-efficiency particulate air (HEPA) filters were installed as an infection control measure, there were only two additional cases of nosocomial aspergillosis in the 2 years following the outbreak.

CONCLUSIONS: This outbreak occurred among hematologic oncology patients with prolonged granulocytopenia housed in an environment with neither HEPA filters nor laminar air flow units. Our data demonstrate that in the setting of an outbreak of aspergillosis, HEPA filters are protective for highly immunocompromised patients with hematologic malignancies and are effective at controlling outbreaks due to air contamination with *Aspergillus* conidia (*Infect Control Hosp Epidemiol* 2002;23:525-531).

Fungal infections are a significant determinant of the morbidity and mortality of selected patients undergoing immunosuppressive therapy for hematologic malignancies.^{1,3} Early stage fungal infections are difficult to diagnose and treat, resulting in a high mortality rate.^{3,5} *Aspergillus* species are common organisms that cause fungal infections in patients with leukemia and lymphoma, second only to infections with *Candida* species.^{6,7} Aspergilli have a ubiquitous distribution in the environment and their conidia are easily transported to distant sites.⁸ In invasive pulmonary aspergillosis, the main route of entry of *Aspergillus* is by inhalation of conidia.^{9,10} Air concentration of conidia and duration of exposure are important factors in the pathogenesis of pulmonary aspergillosis.¹⁰⁻¹²

During the past two decades, invasive pulmonary aspergillosis has been encountered with increasing frequency in patients with hematologic malignancies.^{13,14} The principal host defenses against invasive *Aspergillus* infection are alveolar macrophages, which target inhaled conidia, and neutrophils, which target the hyphal stage. Impairment of these cellular defenses and mucosal immu-

nity by cytotoxic chemotherapy, corticosteroids, and other immunosuppressive agents predispose patients with hematologic malignancies, hematopoietic stem cell transplants, or both to invasive filamentous fungal infections. A major obstacle to successful treatment is the difficulty establishing an early diagnosis. Many *Aspergillus* infections are not diagnosed until late in the course of infection or until post-mortem examination.¹⁵ Thus, aspergillosis outbreaks are underestimated or unnoticed because of the low rate of positive cultures of tissue and sputum samples.

Reported outbreaks of nosocomial invasive pulmonary aspergillosis have been caused by concentration of conidia in hospital ventilation systems,¹⁶ air contamination from construction,^{12,17-24} contaminated fireproofing materials,²⁵ and other sources.^{26,27} Cancer and transplant centers are at high risk for aspergillosis outbreaks. Reported aspergillosis outbreaks have occurred mainly among patients with acute or chronic myeloid leukemia and prolonged neutropenia. Some patients also received cytotoxic chemotherapy, corticosteroids, an allogeneic bone marrow transplant (BMT), or all three. The duration of granulocy-

Drs. Hahn, Lipman, Segal, and McCarthy are from the Department of Medicine; Drs. Hahn and Cummings are from the Department of Cancer Prevention, Epidemiology and Biostatistics; and Dr. Michalek is from the Department of Educational Affairs, Roswell Park Cancer Institute, Buffalo, New York.

topenia is a consistently important risk factor for invasive aspergillosis.²⁸

METHODS

Study Design

Because of the availability of detailed medical records and air sampling, a retrospective cohort design was used to study an outbreak of nosocomial aspergillosis among the patients who were treated on the hematologic oncology unit. All 91 patients admitted to this unit for 4 or more consecutive days between January 1 and December 31, 1992, were included in the study. Patients who were admitted for less than 4 days were excluded because their length of stay was not long enough for them to develop a nosocomial infection and have it detected. All data were analyzed using SPSS software (SPSS Inc., Chicago, IL).

Definition of Aspergillosis

Because this was an outbreak investigation, we used stringent criteria and included only documented proven cases of aspergillosis in this analysis, although definitions of possible and probable cases are available.²⁹ A case of aspergillosis was defined as any patient who had a species of *Aspergillus* isolated from a sinopulmonary culture, from a tissue biopsy specimen, or at autopsy, and who had radiographic evidence of invasive disease, had invasive disease

determined at autopsy, or both. The first positive culture had to have been taken more than 72 hours after the patient was admitted to be considered indicative of nosocomially acquired infection. Because this was a population with neutropenic leukemia, any patient with at least one positive sputum culture and radiographic evidence consistent with invasive fungal infection was assumed to have invasive disease based on prior research.³⁰ Seven of the eight patients who died had an autopsy performed that confirmed the diagnosis of invasive aspergillosis. All patients had *A. flavus* (two also had *A. niger*) isolated from their specimens. Patients suspected of having aspergillosis had clinical symptoms (eg, cough, dyspnea, or neutropenic fever unresponsive to antibiotics) and radiographic findings compatible with invasive fungal infection without confirmatory culture or histopathology. They were treated for invasive fungal infection but were not included in this analysis.

Description of Facilities

In 1992, Roswell Park Cancer Institute facilities included an 8-story main hospital building connected by an aboveground pedestrian walkway to a 4-story satellite building. The satellite building's fourth floor consisted of an office wing and two patient care wings with a shared nurses' station (Fig. 1). The BMT wing had high-efficiency particulate air (HEPA) filtration and four rooms with laminar air flow units (LAFUs). The non-BMT wing housed patients with hematologic disorders who were usually admitted for high-dose chemotherapy without stem cell support. Most of these patients (> 70%) had leukemia. Each unit served as the overflow wing for the other, but all allogeneic BMT patients stayed in the HEPA-filtered environment (BMT wing). All of the rooms in these two units were private. Procedures of staff, cleaning personnel, and maintenance personnel did not differ between the two units.

Air Sampling

Routine surveillance air samples were collected weekly using Mattson Garvin Slit Air samplers (Fred Baker Scientific, Cheshire, United Kingdom). All samples were collected during 60 minutes at a flow rate of 1 cu ft/min, yielding a total volume of air sampled of 1.7 m³. The growth medium was Sabouraud Dextrose Agar, Emmons Formulation pH 7.0 (Remel, Lenexa, KS). Air samples were incubated at 27°C. Air samples were taken in each patient room, office, elevator, and storage room, at the nurses' station, and at intervals in each hallway.

Air Quality or Filtering

The air handling systems for the BMT and the non-BMT units established two different environments. The air intake on the ground floor brought in ambient air that went through two filtering processes, one with 30% efficiency and one with 95% efficiency. The filtered air was delivered to the fourth floor through a single ventilation shaft that split at the fourth floor to supply the two wings. The filtered air was delivered to each room on the non-BMT unit so that there was a positive pressure gradient in each room.

The same filtered air was delivered to the BMT unit. However, four patient rooms in the BMT wing had LAFUs with HEPA filtration (99.7% efficiency) mounted in the wall over the patient's bed. The LAFUs continually provided a uni-directional airflow of 90 linear feet per minute toward the door leading to the hallway. There were also freestanding HEPA filters at intervals in the hallway of the BMT unit. Each patient room on both the BMT unit and the non-BMT unit was filtered with 10 to 12 air exchanges per hour establishing positive pressure of clean to dirty air. Self-closing or air-lock doors were not installed in any patient rooms. No windows were operable and there were no air conditioners installed in individual patient rooms or elsewhere on either unit. The additional air filtering provided by the HEPA filters and LAFUs resulted in fewer *Aspergillus* conidia in the BMT unit compared with the non-BMT unit. This was confirmed with weekly air sampling (Fig. 1) during the outbreak.

RESULTS

There were 10 cases of invasive aspergillosis during 1992, all of which were diagnosed between August and December (Fig. 2). Table 1 summarizes the information on these patients. The incidence of acquiring aspergillosis during the second half of 1992 was 18%, yielding a relative risk estimate of 13.9 ($P = .004$) when compared with the first half of 1992. The presence of immunocompromised patients on two patient care units with different environments (HEPA filtration vs no HEPA filtration) established an unintentional, natural experiment testing the efficacy of HEPA filters.

FIGURE 2. The number of cases of aspergillosis during 1992 by month of diagnosis.

Timing of the Outbreak

The patients admitted during the first half of 1992 were compared with the patients admitted during the second half of 1992 to determine whether there were more high-risk patients during the second half of 1992. As detailed in Table 2, most of the patient characteristics remained unchanged. The median number of febrile days increased significantly ($P = .03$), whereas the median length of stay and duration of neutropenia increased marginally. The proportion of patients with myeloid leukemia increased from 47% to 58%, although this was not statistically significant. The duration of antifungal medication use increased significantly, although this was a result of prolonged antifungal therapy in the cases of aspergillosis.

The mortality rate (31% vs 33%) and the autopsy rate

(14% vs 18%) did not differ significantly between the two time periods. Although eight patients with aspergillosis died during the second half of 1992, the mortality rate did not increase significantly. We therefore believe that the increased number of cases of aspergillosis during the second half of 1992 was not biased by methods of detection.

Location of the Outbreak

The analysis of the location of the outbreak compared the patients admitted to the non-BMT wing with those admitted to the BMT wing during the second half of 1992, when 9 of the 10 patients with aspergillosis were admitted to the non-BMT wing.

The results given in Table 3 indicate that the patients in the BMT wing exhibited more of the risk factors for aspergillosis and would have been considered at high risk for fungal infection. The length of hospital stay (37 vs 30 days; $P = .02$) and the rate of BMT (65% vs 11%; $P < .001$) were significantly greater for patients in the BMT wing compared with patients in the non-BMT wing. The patients in the BMT wing also had trends toward a higher rate of steroid use and a longer duration of neutropenia. Despite these risk factors for aspergillosis, only one case occurred in this group. The outbreak occurred in the patient population considered to be at lower risk for aspergillosis due to high *Aspergillus* conidia counts (> 150 colony-forming units

[CFU]/ m^3) in the non-BMT wing compared with low counts (< 4 CFU/ m^3) in the BMT wing (Fig. 1). The difference in air quality was attributed to the lack of HEPA filtration and LAFUs in the non-BMT wing.

Comparison Between Patients With Aspergillosis and Patients Without Aspergillosis

Table 4 details the analysis of the patients with aspergillosis versus the patients without aspergillosis admitted to the non-BMT wing during the second half of 1992. Nine of 35 patients developed aspergillosis, 7 of whom died. The patients with aspergillosis had a significantly longer duration of fever and antifungal medication use, both of which are measures but not causes of the infection. The only other statistically significant differences between the two groups of patients were in the mortality and autopsy rates. More of the patients with aspergillosis had acute myeloid leukemia or chronic myeloid leukemia, but this difference was not significant. None of the patients with aspergillosis and 31% of the patients without aspergillosis had been admitted for or had had a prior BMT, although this difference also was not significant.

Source of the Outbreak

The source of the outbreak was determined to be the high *Aspergillus* conidia counts found in the non-BMT unit by

routine air sampling during the outbreak. The source of the high conidia counts was investigated and determined to be contaminated insulation in the wall of the fourth floor near the nurses' station, which was the point of the highest conidia counts. Another investigated source was the third floor office wing renovations, which were stopped on October 22, 1992, due to the possibility of contamination of the fourth floor. Although contact samples showed contamination of the work site with *A. flavus* and *A. niger*, the third floor had a separate air handling system. Thus, it was unlikely that the conidia were transported to the hematologic oncology units. Other sources that were investigated included the attic space above the fourth floor, the air handling system, and the outside ambient air, all of which had no conidia counts or counts that were lower than those from the BMT wing.

Air sampling data from the fourth floor taken between October 1 and November 15, 1992, showed the highest conidia counts ($> 150 \text{ CFU}/\text{m}^3$) around the shared nurses' station (Fig. 1). The BMT wing had relatively low conidia counts ($< 4 \text{ CFU}/\text{m}^3$), whereas the non-BMT wing had high conidia counts ($> 100 \text{ CFU}/\text{m}^3$) just inside the double doors separating the hallway from the nurses' station and a progressively declining gradient with low conidia counts ($< 5 \text{ CFU}/\text{m}^3$) at the end of the hallway farthest from the nurses' station. The HEPA filters in the BMT wing removed most of the conidia from the ambient air and the

absence of these filters in the non-BMT wing allowed the gradient to become established.

Infection Control Measures

The increased fungal conidia burden detected by environmental air sampling and the increased number of cases of aspergillosis led to the following infection control measures. On November 9, 1992, HEPA filters were placed at intervals in the non-BMT wing and at the nurses' station. Itraconazole was added to the antifungal prophylactic regimen, the wall insulation was decontaminated, and the third floor construction site was sealed with airtight barriers. Only two additional cases of invasive nosocomial aspergillosis were diagnosed in May 1993 after the initiation of these infection control measures. As of December 1994, 2 years after the outbreak, these were the only cases of nosocomial aspergillosis on the fourth floor. In December 1994, the patients on both wings were moved to two renovated floors of the main hospital with HEPA filtration. The fourth floor of the satellite building was converted to an outpatient clinic in 1995.

It is difficult to assess the efficacy of each infection control measure individually. In retrospect, the itraconazole fungal prophylaxis had little or no effect as a preventive measure due to its limited oral absorption. It is likely that the addition of HEPA filters to the non-BMT

wing led to the reduction in *Aspergillus* conidia and, consequently, to the reduction in the number of cases of aspergillosis.

DISCUSSION

A previous report from our institution of an outbreak of aspergillosis among BMT recipients demonstrated the need for HEPA filtration on BMT units.²⁶ This report demonstrates the efficacy of HEPA filters that have since been installed in our BMT unit and the additional need of this protective environment for patients with hematologic malignancies who are immunocompromised from therapies other than BMT. This study provides evidence-based information regarding the necessity and efficacy of HEPA filtration in hematologic malignancy units.

The main limitations of this study are the underestimation of cases, the unavailability of DNA analysis techniques, and the limited applicability and generalizability of this study to other institutions. Nine of the 35 patients admitted to the non-BMT wing were confirmed cases of aspergillosis. An additional 5 patients were suspected of having aspergillosis but were not included as cases because their sputum cultures were negative for *Aspergillus* and no biopsies or autopsies had been performed. The comparison between patients with aspergillosis and patients without aspergillosis on the non-BMT wing during

the second half of 1992 probably failed to yield any statistically significant differences because of the underestimation of cases and the small sizes of the groups.

Circumstantial evidence points to the wall insulation at the nurses' station as the source of the gradient of *Aspergillus* conidia in the non-BMT wing because it was located where the highest *Aspergillus* conidia counts were recovered. The moldy insulation we believe was the source of the outbreak was not suddenly disturbed by construction or other movement that would have contributed to a sudden increase in conidia concentrations. We speculate that the contamination of the insulation occurred concurrent to the sudden spike in *Aspergillus* conidia.

This outbreak occurred before the recent advances in the diagnosis of aspergillosis^{31,32} and the development of molecular techniques to determine point sources.^{33,34} These diagnostic tests may have detected additional cases; however, when molecular techniques became available, the samples either were not sufficient for adequate DNA analysis or had already been discarded. Random amplification of polymorphic DNA analysis could have helped identify the source of the outbreak or determine whether the patients with aspergillosis were infected from one or multiple sources. However, the identification of *A. flavus* from all cases is unusual and suggests a true outbreak from a single

source rather than multiple sporadic cases. On the basis of this study's results, we recommend that HEPA filters be used routinely in hospital units housing patients with hematologic malignancies and prolonged neutropenia. This study confirms previous findings of the efficacy of HEPA filters in controlling aspergillosis outbreaks.^{20,23,24,35,36}

The effect of pressure differential and care provider movement on airborne infectious isolation room containment effectiveness

Noah J. Adams, MS, David L. Johnson, PhD, and Robert A. Lynch, PhD
Oklahoma City, Oklahoma

Background: Airborne infectious isolation rooms (AIIRs) are maintained at a negative pressure relative to surrounding areas to prevent migration of potentially infectious droplet nuclei. Current US design standards require a pressure differential of only 2.5 Pascals (Pa), compared with 15 Pa in some other countries. The purpose of this work was to compare containment efficiency in a properly designed anteroom-equipped hospital AIIR at differential pressures ranging from 2.5 to 20 Pa under conditions of no provider traffic and simulated high provider traffic.

Methods: Fluorescent microspheres were released into the AIIR to simulate infectious droplet nuclei. Airborne concentrations were measured inside the AIIR, in the anteroom, and at the corridor-anteroom door both with and without care provider movement through the AIIR under differential pressure conditions of 2.5, 11, and 20 Pa. Particles were collected by air sampling onto filters, with enumeration via fluorescent microscopy.

Results: Reduced containment effectiveness during provider traffic was observed, consistent with previous studies. Containment increased with increasingly negative pressure differential and decreased with increasing provider traffic.

Conclusions: Provider traffic adversely affected containment. Containment improved with an increasing pressure differential. The anteroom plays an important role in limiting net particle escape, especially during provider movement through the space.

Key Words: AIIR; droplet nuclei; anteroom; air volume migration.

The Centers for Disease Control and Prevention (CDC) identifies two measures for controlling airborne disease in health care facilities: (1) the use of administrative measures to reduce the risk of exposing uninfected persons to persons who have disease that is infectious by the airborne route, and (2) the use of engineering controls to prevent the spread and reduce the concentration of infectious droplet nuclei.¹ The use of hospital airborne infectious isolation rooms (AIIRs) involves both of these strategies.^{2,3} AIIR ventilation systems maintain a negative air pressure inside the room relative to the surrounding areas by mechanically removing (exhausting) more air than is supplied,

causing the room to be at slightly negative atmospheric pressure relative to surrounding areas. This is intended to cause air to flow into rather than out of the room through open doors, cracks, or other penetrations and thereby prevent airborne droplet nuclei from escaping the space.³ Numerous factors can interfere with proper AIIR performance, and although a negative pressure differential is necessary for correct air flow direction, it does not guarantee it.³

AIIR DESIGN STANDARDS

The *Guidelines for Design and Construction of Hospital and Health Care Facilities*⁴ has been accepted as the primary standard governing AIIR design in the United States.⁵ The American Society of Heating, Refrigerating, and Air-Conditioning Engineers and the CDC have provided additional information and recommendations on ventilation design performance.^{5,6} These US standards require a minimum pressure differential of only 2.5 Pa,⁴⁻⁶ whereas international standards require a minimum differential of as much as 15 Pa.^{7,8} US and international standards are in agreement regarding a required exhaust rate of 12 air changes per

hour (ACH) in the AIIR, with at least 2 ACH of fresh air brought in from the outside. An anteroom is recommended as a transition from the potentially contaminated AIIR to the adjacent health care facility;⁶ health care providers typically use this space to don and doff personal protective equipment, such as respirators, gloves, and gowns.

EFFECT OF PROVIDER MOVEMENT ON AIIR CONTAINMENT

The literature contains little information regarding the airborne pathogen containment efficiency of AIIRs during provider movement into and out of the space at various ventilation conditions, but air volume migration (AVM), the escape of a parcel of air from the AIIR, has been demonstrated. Holding AIIR rooms at negative differential pressure relative to surrounding areas is essential. Beggs⁹ reported that the most common reason for loss of pressure differential in isolation rooms is the opening of doors. Several studies have demonstrated the adverse effects of door opening and provider movement on AIIR containment effectiveness,¹⁰⁻¹² including a tracer gas study by Rydock and Eian¹² that evaluated 4 “state-of-the-art” AIIR rooms in Norway with pressure differentials of 15 Pa between the corridor and anteroom and 30 Pa between the corridor and patient room, both of which greatly exceed US requirements. Sulfur hexafluoride (SF₆) was released at the patient bed position and allowed to mix in the room for 2 minutes before the release technician exited the room into the anteroom. The technician waited an additional 3 minutes in the anteroom before entering the adjacent corridor. Subsequently, SF₆ was readily detected in both the anteroom and the corridor, indicating that the AIIR did not contain all of the gas during provider movement even at this high pressure differential. Recent work by Johnson et al¹³ also demonstrated greatly reduced containment efficiency during simulated provider traffic into and out of an expedient isolation enclosure, such as might be used during a surge in demand for isolation capacity. We found no study that evaluated the effect of provider movement in a single facility over the range of recommended pressure differentials, however. The purpose of the present study was to compare containment efficiency in a properly designed, anteroom-equipped hospital AIIR at differential pressures ranging from 2.5 to 20 Pa under conditions of no provider traffic and simulated high provider traffic.

MATERIALS AND METHODS

This study evaluated the containment effectiveness of an AIIR with an anteroom under 3 different negative

pressure conditions with and without health care provider movement through the space. Uniformly sized 2- μ m-diameter green fluorescent polystyrene latex (PSL) microspheres (Duke Scientific, Palo Alto, CA), which simulate airborne pathogens, were distributed into an AIIR from water suspension using a medical air jet nebulizer. PSL microspheres were used because they are nonpathogenic, are the same size as many airborne pathogens, and fluoresce to make their identification more specific. Because the PSL microspheres are aerodynamically similar to airborne bacterial pathogens, they have the same transport behavior in air and thus have a similar potential to escape the AIIR. Once aerosolized, the particles were collected on preloaded 25-mm diameter, 0.8- μ m pore size mixed cellulose ester filters in conductive cowed cassettes (model 225-321; SKC, Eighty-Four, PA). The air sampling rate was 1.5 L/min. Each filter was transferred from the cassette to an oversized microscope slide (75 $\times$ 38 mm) and covered with a 35 $\times$ 50 mm slip tacked down with drops of clear fingernail polish. The sample was labeled with a unique identification number. To distinguish fluorescent particles from background particles, the filters were viewed using a Nikon Eclipse 80i top-illuminated fluorescence microscope fitted with a Prior Optiscan 29 motorized stage, Nikon DXM 1200 digital camera, and NIS Elements image analysis software (AR 2.10, Build 215) (all from Nikon Instruments, Melville, NY). Slides with dense particle deposition were counted at 40 $\times$ magnification using a random field technique, whereas the total surface of slides with light particle deposition was manually counted according to the method of Johnson and Lynch.¹⁴ The low (40 $\times$) magnification could be used because the fluorescent image of the deposited particle was much larger than its 2- μ m physical diameter. The time-weighted average airborne particle concentration estimate for each filter sample was calculated from the filter count, the average pump flow rate during the sample, and the sampling time.

The study took place in a major medical center in Oklahoma City, Oklahoma. The particular AIIR studied was selected because it had an anteroom, adjustable return air ventilation that enabled adjustment of the exhaust airflow and resulting negative pressure, and a high exhaust flow capable of achieving differential pressures exceeding 20 Pa. Swing-in type doors joined the corridor and the anteroom and the anteroom and the AIIR. Because this research project involved one human subject to simulate provider movement, Institutional Review Board approval was secured. The human subject wore surgical scrubs, rubber gloves, safety goggles, and an N95 respirator and played the role of a health care provider moving into and out of the space. Personal protective equipment was worn primarily to simulate a “real world” scenario.

The following protocol was followed during the trials that involved health care provider movement. The nebulizer was started remotely and allowed to operate for 15 minutes before the subject entered the room. After these 15 minutes, the subject opened the outer anteroom door, entered the anteroom, closed the door and waited 5 minutes, opened the inner anteroom door, moved into the patient area, closed the door and waited 5 minutes, opened the inner anteroom door and moved back into the anteroom, closed the door and waited 5 minutes, opened the outer anteroom door and exited the anteroom to the outside, and then closed the door and waited 5 minutes. The subject repeated these steps for a total of 3 cycles. The experiment involving the human subject was repeated 3 times for each of 3 pressure differentials, for a total of 9 trials. Each trial required 90 minutes of air sampling.

During the no-movement trials, the sampling pumps and the nebulizer were started remotely as in the movement trials, and after 90 minutes the cassette from each sampling pump was collected and labeled. No human subject moved to and from the rooms during the 90-minute no-traffic trials.

The initial 15-minute nebulization time before entry of the subject into the room was chosen to allow the room particle concentration to come to equilibrium after starting the nebulizer, and was based on the experimentally determined effective ventilation rate of the central area of the AIIR. The effective ventilation rate, Q'_{ACH} , expressed in air changes per hour (ACH), is the total fresh air ventilation rate, Q (eg, ft³/hour), divided by the room volume V (ft³/air change) and a dimensionless factor K that takes into account the reduction in dilution efficiency caused by less than perfect air mixing in the room, that is, $Q'_{ACH} = \frac{Q}{KV}$.¹⁵ Because K is generally unknown for a space, experimental determination of Q'_{ACH} is useful in estimating the nebulization time required to reach an equilibrium concentration. We estimated Q'_{ACH} for the AIIR using an approach similar to that of Pavelchak et al.¹⁶ In brief, air current tracing “smoke” (airflow indicator tubes model 810-500; SKC) was released into the AIIR in puffs as the investigator walked 3 times around the room. The multipoint release and motion of the investigator were intended to promote good particle distribution in the space. The ventilation system was operating at a 20-Pa pressure differential, with a supply flow rate of 185 cfm and an exhaust flow rate of 820 cfm. The subsequent “decay” in the smoke concentration was measured over time as it was diluted by the ventilation system. Theory predicts that once particle generation is stopped, the airborne particle concentration will decrease in an exponential fashion according to the equation $C' = e^{-\frac{Q}{KV}t}$ or $C' = e^{-Q'_{ACH}t}$, where C' is the normalized concentration (ie, the fraction of the initial concentration

remaining at time t). The $\frac{Q}{KV}$ or Q'_{ACH} exponential decay constant physically represents the effective ventilation rate of the AIIR expressed in air changes per unit time. The logarithmic form of the exponential decay equation is $\ln(C') = -Q'_{ACH}t$, and from this relationship we easily estimated the decay constant by linear regression with the line constrained to pass through a zero intercept. We took this value to be representative of the decay constant in the central area of the room in which the samplers were located. This estimate, which was 0.4745 air changes per minute or 28.47 ACH ($R^2 > 0.96$), then allowed us to calculate the time required to reach 90% of the equilibrium particle concentration C_{eq} during aerosol generation. Assuming exponential concentration buildup following the relation $C = C_{eq}(1 - e^{-Q'_{ACH}t})$,¹⁵ the nebulization time, in minutes required to reach 90% of C_{eq} , was calculated as

$$t = -\frac{1}{Q'_{ACH}} \ln\left(1 - \frac{C}{C_o}\right) = -\frac{1}{0.4745 \text{ min}^{-1}} \ln\left(1 - \frac{.9C_{eq}}{C_{eq}}\right) \\ = 2.303/0.4745 = 4.85 \text{ min.}$$

Measurement of exhaust ventilation rates at 20 Pa (185 cfm supply, 820 cfm exhaust), 11 Pa (175 cfm supply, 632 cfm exhaust), and 2.5 Pa (163 cfm supply, 295 cfm exhaust) indicated that the 15-minute nebulization period allowed before the start of sampling would be adequate to reach 90% of the equilibrium under all pressure (and exhaust flow rate) conditions used provided that no large differences in room air mixing characteristics occurred over this range of pressure differentials and air flow rates.

The nebulizer simulated a patient continually producing airborne particles through coughing, sneezing, and talking. A modified device was used that provided continuous replenishment of PSL particle source suspension via an injection pump (Figs 1 and 2). A dual-syringe infusion pump (model 200; KD Scientific, Boston, MA) fitted with two 30-mm-diameter, 60-mL syringes supplied the nebulizer with a constant suspension feed rate of 1 mL/min over a 90-minute period. An exit port that directed overflow to a 500-mL Erlenmeyer flask ensured a constant volume of suspension in the reservoir. A medical nebulizer compressor (ProNeb Ultra model 85B0000, Pari Innovative Manufacturers, Midlothian, VA) operating at 20 psi pressure provided a consistent air flow rate of 4.41 L/min, as measured with an air flow calibrator (DryCal model DC Lite, BIOS International, Butler, NJ).

AIIR containment was assessed by measuring PSL concentrations inside and outside the AIIR in the presence and absence of provider traffic. Particle concentrations were measured at 4 locations inside the AIIR, 2 locations in the anteroom, and 4 locations outside the corridor-anteroom door (10 total) at each of

Fig 1. Nebulization system. The nebulization system comprised a medical air jet nebulizer modified to allow the continuously replenishment of the reservoir with particle source suspension via an infusion pump.

3 pressure differential conditions (2.5 Pa, 11 Pa, and 20 Pa) for each of two traffic conditions (no traffic or 3 provider passes through the AIIR), with 3 replicates of each trial. This resulted in 10 filter samples $\times$ 3 pressure differentials $\times$ 2 traffic conditions $\times$ 3 replicates = 180 samples.

Pressure differentials for each experimental condition were measured between the corridor and patient room and between the anteroom and patient room using a digital micromanometer pressure meter (model DM-4; Infiltec, Waynesboro, MA). Pressure differential readings were taken by placing one of the two micromanometer sensing hoses inside the room and running the second hose under the doorway into the corridor. The instrument displayed the resulting pressure differential between the spaces. Visual smoke tests to trace air current direction also were performed throughout the study to ensure maintenance of appropriate pressure gradients. An Alnor standard balometer “flow hood” (TSI, St Paul, MN) was used to measure the exhaust air flow rates.

Fig 2. Modified nebulizer. Continuous replenishment with an excess of particle suspension prevented depletion of the suspension during the 1.5-hour nebulization periods.

During each trial, 4 air-sampling pumps (SKC 224-PCXR4 or MSA Escort ELF [Mine Safety Appliances, Pittsburgh, PA]) were placed in the 4 quadrants of the patient care area. Before sampling, the pumps were calibrated to a flow rate of 1.50 ± 0.03 L/min using the air flow calibrator, and the values were recorded. The flow was measured again after sampling to verify consistent operation and determine the average flow rate for the trial. The pumps were placed on tabletops approximately 30 inches above the floor. Each pump was fitted with a preloaded 25-mm-diameter mixed cellulose ester filter. Two pumps with filters were also placed on a countertop in the anteroom, and 4 additional pumps with filters were placed outside of the anteroom door in the corridor. The pumps in the corridor were placed on stands on each side of the door at elevations of 3 feet and 6 feet, with two on each side of the door. These pumps were positioned within 1 foot of each side of the doorway.

Conditions for the experiment were as follows. An extension cord was run from the nebulizer compressor

Table 1. Corridor-to-room and anteroom-to-room particle concentration ratios

	Mean measured differential pressure					
	Anteroom to patient care area			Corridor to patient care area		
	1.5 Pa	7.3 Pa	12.5 Pa	2.1 Pa	10.7 Pa	20.7 Pa
Without provider traffic	7.00×10^{-4}	2.38×10^{-4}	1.62×10^{-4}	3.55×10^{-4}	1.20×10^{-4}	0
	2.06×10^{-3}	2.72×10^{-4}	1.23×10^{-4}	3.07×10^{-4}	6.98×10^{-5}	0
	1.59×10^{-4}	0	0	1.05×10^{-4}	1.45×10^{-4}	3.90×10^{-4}
With provider traffic	5.12×10^{-2}	1.55×10^{-2}	1.10×10^{-2}	3.84×10^{-4}	6.04×10^{-4}	2.04×10^{-4}
	5.60×10^{-2}	1.79×10^{-2}	1.13×10^{-2}	5.03×10^{-4}	5.40×10^{-4}	2.86×10^{-4}
	4.25×10^{-2}	1.57×10^{-2}	1.08×10^{-2}	7.99×10^{-4}	1.21×10^{-4}	0

NOTE. Values represent the ratio of the mean particle concentration in either the corridor or the anteroom to the mean particle concentration inside the room for each sampling event.

into the hallway so that the nebulizer could be started without having to enter the room. The room's ventilation system was adjusted to provide a nominal differential pressure of 2.5, 11, or 20 Pa by controlling the amount of exhausted air. The AIIR chosen for this study had a normal operating differential pressure exceeding 20 Pa, so the target differentials were achieved by physically obstructing a portion of the exhaust air grill to "choke" the exhaust flow. At each pressure differential condition, smoke tests were conducted between the AIIR and anteroom and anteroom and corridor to visually verify the correct air flow direction, ensuring an appropriate pressure gradient. Corridor-AIIR and anteroom-AIIR pressure differentials were measured with a digital micromanometer for each pressure condition. Pump air flow rates were remeasured after each trial and recorded.

RESULTS AND DISCUSSION

Of the 180 filter samples obtained, 4 were discarded due to either pump failure during the trial or unacceptable variation in the before-and-after pump flow rate measurements ($>10\%$ or 0.15 L/min). Three of the discarded samples were from inside the AIIR and the other was from inside the anteroom, and no more than one sample was lost in any one trial. Owing to intermittent operation of the building's heating, ventilation, and air-conditioning (HVAC) system, pressure differentials were seen to vary somewhat from the target levels of 2.5, 11, and 20 Pa. The mean measured differentials were 2.1 Pa (range, 1.2-2.5 Pa), 10.7 Pa (range, 9.4-12.0 Pa), and 20.7 Pa (range, 20-21.3 Pa). These differentials were measured at one point in time before each trial, and due to the intermittent operation of the building's HVAC system might not represent the mean pressure differential for the entire 90-minute trial. Mean patient care area exhaust air flow rates were 208 cfm (range, 198-218 cfm), 434 cfm (range, 413-445 cfm), and 660 cfm (no variation). Mean

pressure differentials between the patient care area and the anteroom were 1.5 Pa (range, 0.9-3.1 Pa), 7.3 Pa (range, 6.6-7.5 Pa), and 12.5 Pa (range, 12.2-13.9 Pa). The anteroom did not have its own supply or exhaust; air was drawn into the anteroom from the corridor via a gap under the door and passed through to the patient care area of the AIIR.

The maximum particle count for any sample collected outside the corridor door was 5, compared with filter counts of approximately 2500-4500 inside the AIIR for the same period. The mean counts for the 2.5-, 11-, and 20-Pa pressure conditions were 1.08, 0.42, and 0.25 in the absence of provider traffic and 1.83, 1.50, and 0.42 with provider traffic. The corresponding mean corridor particle concentrations were approximately 8.1, 3.1, and 1.9 particles/ m^3 in the absence of provider traffic and 13.6, 11.2, and 3.1 particles/ m^3 with provider traffic.

The maximum particle count for any sample collected in the anteroom was 242. The mean counts for the 1.3, 7.5, and 12.5 Pa pressure conditions were 5.17, 0.60, and 0.33 in the absence of provider traffic and 156.5, 52.8, and 29.0 with provider traffic. The corresponding mean anteroom particle concentrations were approximately 38.2, 4.5, and 2.5 particles/ m^3 in the absence of provider traffic and 1149, 393, and 215 particles/ m^3 with provider traffic.

Table 1 presents the ratio of mean particle concentrations in the corridor to those in the AIIR patient care area, as well as the ratio of mean anteroom concentrations to mean patient care area concentrations, for each of the 9 trials. As noted by Johnson et al,¹³ the particle concentration measured in the corridor immediately outside the room entrance is only a relative measure of the degree of particle escape from the room. This is due to the inability to contain all of the air in the vicinity of the door during sampling, with subsequent particle dispersion by room currents. Thus, absolute containment efficiencies that might be calculated from the "escape fraction" estimates

Fig 3. Relative particle escape from the patient area to the corridor. Net particle escape to the corridor from the patient care area at different pressure differentials with and without provider traffic is shown relative to the observed particle escape under the 2.5-Pa, no-traffic condition.

represented by Table 1 would be overestimates of the true containment. However, the measures are illustrative of the *relative* containment under the various conditions when one of the conditions is taken as the baseline.

Figure 3 graphically presents corridor-to-room concentration ratios at the three pressure differential conditions with and without provider movement, relative to the ratio observed at the 2.5-Pa, no-traffic condition. That condition was chosen because it represents the US design standard. The figure reflects a decrease in particle escape as the negative pressure differential increases from 2.5 Pa to 20 Pa for both the no-traffic and with-traffic conditions. It also reflects much greater particle escape during provider traffic compared with the no-traffic condition at 2.5 Pa, but with a diminishing traffic effect at 11 Pa and little or no difference in escape at 20 Pa.

Figure 3 appears to indicate improved containment at pressure differentials above 2.5 Pa, especially in the presence of provider movement. However, although a two-way analysis of variance (ANOVA) of the data in Table 1 (data not shown) indicated a statistically significant difference ($P < .03$) in containment across the traffic conditions, it did not show a significant difference due to the pressure differential ($P = .09$); the traffic–pressure interaction term was also not statistically significant ($P = .36$). Whether this result is due to an actual lack of effect, to the small sample size, or to variations in differential pressure during trials or other sources of imprecision, with subsequently low statistical power to detect the real differences, is unclear. A larger-scale study is needed to improve statistical power and resolve this question.

Figure 4 illustrates the substantial contribution of the anteroom in limiting the net escape of particles

Fig 4. Relative particle escape from the patient area to the anteroom. Particle escape to the anteroom from the patient care area at different pressure differentials with and without provider traffic is shown relative to the observed particle escape under the 2.5-Pa, no-traffic condition.

from the patient care area to the corridor. Whereas a 50-fold increase in particle escape occurred during provider traffic relative to no traffic at the lowest differential pressure, this translated to only a roughly 2-fold increase in net particle escape to the corridor from the patient care area. There again appeared to be a decrease in particle escape with increasing pressure differential for both traffic conditions, as supported by a two-way ANOVA in which traffic condition, differential pressure, and their interaction were all statistically significant ($P < 10^{-6}$). The anteroom was clearly effective in limiting the migration of particles out of the AIIR, even though its only ventilation was by pass-through air.

Interpreting our results is complicated somewhat by the question of air flow rate into the AIIR through the door undercut and other leakage points while the door is closed, and through the door opening while the door is in operation. These flows were not measured in the present study. Gill^{17,18} and Streifel¹⁹ have suggested that a makeup air flow rate in the range of 100–130 cfm through one door to a well-sealed AIIR can effectively minimize air volume migration. Gill¹⁸ reported that a 130-cfm flow through the undercut of a closed AIIR door resulted in a pressure differential of about 12.5 Pa. Wiseman²⁰ recommended a differential air flow rate of 400 cfm that can be “throttled down” to a lower flow adequate to maintain a 2.5 Pa pressure differential when the AIIR door is closed. In an extremely well-sealed AIIR, a pressure differential of perhaps 11 Pa might be achieved with a much lower differential air flow rate than would be required in a less well-sealed AIIR. However, in that case the well-sealed AIIR might then have less effective containment when the door is open due to the lower differential

flow. Apparently, the most effective design approach would include a minimum pressure differential during door-closed conditions and a minimum differential air flow during door-operating conditions.

CONCLUSIONS

The reduced containment effectiveness during provider traffic observed in this study is consistent with previous studies that demonstrated substantial air volume migration during AIIR door operation and provider movement into and out of a space. Although the specific quantitative results presented here are particular to the conditions used in this study, they appear to indicate that AIIR containment effectiveness in the presence or absence of provider traffic may increase with increasing pressure differential. It may be that pressure differentials greater than the current 2.5 Pa US design standard (say, on the order of the 15 Pa standard used in other countries) would be more protective in controlling the escape of airborne droplet nuclei from an AIIR during care provider movement into and out of the room. The limited scope of the present study does not allow us to draw a firm conclusion in this regard, and additional work is needed to explore this question. As shown by Rydock and Eian,¹² even differential pressures in the 15 Pa range might not be sufficient to completely prevent air volume migration during provider movement, and it must be recognized that whether or not a particular pressure differential would be adequately protective in a specific circumstance is a complex question. "Adequate" protectivity depends on a variety of factors, including the infectivity and potential health effects of the threat organism, the frequency and pattern of provider traffic into and out of the AIIR, and the degree of droplet nuclei dilution provided in the interior of the AIIR by the HVAC system and perhaps supplemental free-standing HEPA filtration devices. In this study, the anteroom was found to play an important role in controlling net particle migration from the AIIR patient care area to the corridor, especially in the presence of provider traffic. Additional studies of AIIR containment effectiveness under real-world patient care conditions, in the presence and absence of an anteroom, would provide the more detailed information needed to consider further refinements to AIIR design standards.

The authors gratefully acknowledge the staff members of the Environmental Health and Safety Office and the Pediatric Intensive Care Unit of the Integris Baptist Hospital, Oklahoma City, for their kind assistance and cooperation in allowing the use of one of their AIIR units for this study.

A Nosocomial Outbreak of Multidrug-Resistant Tuberculosis

Thomas A. Kenyon, MD, MPH; Renee Ridzon, MD; Roberta Luskin-Hawk, MD; Carol Schultz, RN; William S. Paul, MD, MPH; Sarah E. Valway, DMD, MPH; Ida M. Onorato, MD; and Kenneth Castro, MD

Background: An outbreak of seven cases (in six patients and one health care worker, all of whom had AIDS) of multidrug-resistant tuberculosis occurred in a hospital in Chicago. The hospital had a respirator-fit testing program but no acid-fast bacilli isolation rooms.

Objective: To identify risk factors for transmission of *Mycobacterium tuberculosis*.

Design: Retrospective cohort study.

Setting: Private hospital.

Participants: Patients and health care workers exposed to *M. tuberculosis*.

Measurements: Analysis of *M. tuberculosis* isolates, tuberculin skin testing, assessment of exposure, and assessment of participant characteristics.

Results: All seven *M. tuberculosis* isolates had matching DNA fingerprints. Of patients exposed to *M. tuberculosis*, those who developed tuberculosis had lower CD4⁺ T-lymphocyte counts ($P = 0.02$) and were more likely to be ambulatory ($P = 0.03$) than those who did not. Of 74 exposed health care workers, the 11 (15%) who had conversion on tuberculin skin testing were no more likely than those who did not have conversion to report that they always wore a respirator with a high-efficiency particulate air filter.

Conclusions: Transmission of *M. tuberculosis* occurred in a hospital that did not have recommended isolation rooms. A respirator-fit testing program did not protect health care workers in this setting.

Nosocomial outbreaks of tuberculosis have affected recommendations for infection control practices in hospitals in the United States (1–8). Administrative and environmental measures and respiratory protection for health care workers have been recommended (9, 10). Evidence suggests that adherence to these guidelines may be effective in preventing nosocomial transmission of *Mycobacterium tuberculosis* (11–13).

Of the 34 cases of multidrug-resistant tuberculosis (resistant to at least isoniazid and rifampin) that were reported to the Chicago Department of Health from January 1994 through April 1995, 6 occurred in patients with AIDS who had been admitted to one floor of one hospital. Because nosocomial transmission of multidrug-resistant tuberculosis was suspected, an investigation was initiated.

Methods

Potential outbreak cases—cases of tuberculosis in persons whose isolates were resistant to at least isoniazid and rifampin—were identified by matching the names of patients and health care workers at the hospital to state and local tuberculosis registries and by reviewing laboratory records and death certificates. We performed DNA fingerprinting of *M. tuberculosis* isolates using IS6110 and pTBN12 probes (14, 15).

Medical records were reviewed for patients who were admitted to the outbreak floor when a patient whose sputum smears were positive for acid-fast bacilli was present. Patients who died within 30 days of exposure were excluded.

Private providers of patients who may have been exposed to *M. tuberculosis* were contacted by telephone or by mail. All were advised to screen their patients for tuberculous disease and infection by tuberculin skin tests and symptom checks. A positive result on a tuberculin skin test was defined as induration of 5 mm or more, and an increase in induration of at least 5 mm was considered a skin test conversion. Severely immunocompromised patients (CD4⁺ T-lymphocyte count < 50 cells/mL) who did not receive skin testing were assumed to be anergic (16).

To assess exposure of health care workers to *M. tuberculosis*, we reviewed work schedules, chart signatures, and patient assignments. Results of testing for fit of respirators with high-efficiency particulate air (HEPA) filters and results of annual tuberculin skin tests were obtained from employee records. Health care workers also completed a form about infection control practices and exposure to *M. tuberculosis*.

Acid-fast bacilli isolation rooms (that is, rooms in

Figure. Timeline demonstrating two chains of nosocomial transmission of tuberculous organisms between August 1994 and September 1995 in a hospital in Chicago.

which the air pressure is negative in relation to the hallway and that have ≥ 6 air changes per hour) were installed in December 1994. The design of the ventilation system on the outbreak floor was reviewed, and smoke tube testing was done to assess the direction of air flow.

Data analysis was conducted using Epi Info, version 6 (17). Categorical variables were compared using the chi-square test, and relative risks with 95% CIs were derived. Continuous variables were compared using the Wilcoxon rank-sum test.

Results

Seven persons had outbreak cases of tuberculosis: six patients already known and one health care worker identified during the investigation. All of these persons had AIDS. All of their *M. tuberculosis* isolates were resistant to isoniazid and rifampin and had identical DNA fingerprints. Two generations of nosocomial transmission were identified (**Figure**). Case-patient 1 was admitted to the hospital with a diagnosis of tuberculosis; was placed in a private room; and began receiving therapy with isoniazid, rifampin, pyrazinamide, and ethambutol. From the time this patient was admitted, persons entering the patient's room were required to use HEPA-filter respirators. Case-patient 1 refused to remain in the room and was the source of infection for case-patient 2, who was hospitalized at the same time across the hallway.

Case-patient 2 was readmitted to the hospital 10 weeks later with fever, sinus pressure, and cough. Because the chest radiograph at admission was normal, tuberculosis was not initially suspected. A spu-

tum smear obtained 3 days after admission was positive (3+) for acid-fast bacilli. Treatment with isoniazid, rifampin, and ethambutol was started, and persons entering the patient's room were required to use HEPA-filter respirators. It was reported that the door to the patient's room was malfunctioning and failed to remain closed. Case-patient 2 remained in his room and yet was the source of infection for case-patients 3, 4, 5, and 6, who were hospitalized on the same ward. Transmission to case-patient 6, who was restricted to bed rest, occurred during this patient's short 23-hour hospitalization. Case-patient 7, the health care worker, drew blood from case-patient 2 before case-patient 2 received a diagnosis of tuberculosis and occasionally worked on the outbreak floor while case-patients 1 and 2 were present. For case-patients 2, 3, 4, 5, 6, and 7, no exposure to *M. tuberculosis* other than that which occurred in the hospital was identified. Case-patients 1 and 2 were never in an acid-fast bacilli isolation room while they were infectious because no such rooms were available until December 1994. Case-patients 4, 5, 6, and 7 were all placed in acid-fast bacilli isolation rooms when tuberculosis was suspected; case-patient 3 did not have sputum samples smear-positive for acid-fast bacilli. Smoke tube testing done in April 1995 revealed that the rooms occupied by case-patients 1 and 2 while these patients were infectious had air pressure that was positive in relation to the hallway. The acid-fast bacilli isolation rooms had air pressure that was negative in relation to the hallway. Ultraviolet germicidal irradiation was not used in the hospital.

The outbreak floor was composed of two separate wings with a central nursing station. Of the 169 patients on the floor, 5 had tuberculosis (case-

patients 2, 3, 4, 5, and 6). Of the 164 patients who did not have tuberculosis, 71 (43%) had AIDS. Fifty-three of the 164 patients died before completing screening; none (including 37 patients with AIDS) received a diagnosis of tuberculosis. Of the remaining 111 patients, 5 had positive results on tuberculin skin testing, 34 had negative results, 5 had previously had positive results, 27 were anergic, and 40 had unknown test results. All 5 patients with positive test results had other risk factors for *M. tuberculosis* infection (for example, foreign birth).

All 5 patients were on the same ward as case-patients 1 or 2 while these patients were infectious. No evidence of transmission among patients who did not have AIDS or patients exposed only to case-patients 3, 4, 5, or 6 was identified. Twenty-six patients with AIDS (all of whom were known or presumed to be anergic) were exposed to case-patients 1 or 2. At the time of exposure, case-patients had lower CD4⁺ T-lymphocyte counts than non-case-patients and were more likely to be ambulatory (Table).

Of the 104 exposed health care workers, 17 who had previously had positive results on skin tests and 13 who had resigned from the hospital were excluded from analysis. Of the remaining 74, 11 (15%) had tuberculin skin test conversions (6 nurses, 4 housestaff physicians, and 1 ward secretary) and 4 had positive skin test results, but no baseline test results. None had any other identified exposure to tuberculosis. The remaining 59 (80%) had negative results on skin testing at least 12 weeks after exposure. Except for case-patient 7, no health care worker developed tuberculosis.

Case-patient 2 was the source of most of the episodes of transmission to health care workers. While case-patient 2 was hospitalized with infectious tuberculosis, health care workers with skin test con-

versions worked more days on the floor than did health care workers with negative test results. Health care workers who had conversion were no more likely to have provided direct care to a case-patient, including case-patient 2, than were workers with negative test results (Table).

Forty-two (57%) of 74 exposed health care workers responded to questions about infection control practices. Those with negative test results were no more likely than those with skin test conversion to report always wearing a HEPA-filter respirator when entering the room of a patient with tuberculosis (25 of 29 workers compared with 4 of 5 workers; 8 workers did not recall whether they used HEPA-filter respirators). The results of respirator-fit testing before exposure were available for 68 health care workers; 62, including 80% of those with skin test conversions, passed this testing.

Discussion

This investigation provides evidence of nosocomial transmission of multidrug-resistant *M. tuberculosis*, including 1) exposure of case-patients who had secondary cases of tuberculosis to a source case-patient on the same floor of the hospital; 2) consistency of incubation periods with those of previous nosocomial outbreaks among patients with AIDS (1–3); 3) isolates with matching patterns of drug susceptibility and DNA fingerprints; 4) lack of any other identified exposure to tuberculosis; and 5) exposure of all health care workers with skin test conversion to a case-patient who was not in an acid-fast bacilli isolation room.

Several factors may have contributed to the transmission of *M. tuberculosis*, but the evidence for the role of insufficient environmental controls is

Table. Risk Factors for Nosocomial Transmission of *Mycobacterium tuberculosis* among Patients and Staff

Risk Factor	Persons with Tuberculosis (n = 5)	Persons without Tuberculosis (n = 21)	Rate Ratio (95% CI)	P Value	Persons with Conversion on Tuberculin Skin Testing (n = 11)	Persons Negative on Tuberculin Skin Testing (n = 59)	Rate Ratio (95% CI)	P Value

* Values given are numbers of patients.

† Values given are numbers of health care workers.

most compelling. Case-patients 1 and 2 were both infectious, and the flow of contaminated air from their rooms (which had air pressure that was positive in relation to the hallway) facilitated the spread of infectious droplet nuclei throughout the outbreak floor. Organisms were transmitted to health care workers who did not directly care for a patient with infectious tuberculosis and to one secretary who did not have patient care responsibilities. In this situation, a respiratory protection program did not prevent transmission to health care workers; these findings are consistent with previous evidence that inadequate environmental controls were an important factor in nosocomial transmission (8). Case-patients 1 and 2 were both placed on antituberculous medication either at admission or within 3 days of admission, but the delayed recognition of and inadequate therapy for multidrug-resistant tuberculosis could have contributed to transmission. In many other reports (2-7), delayed recognition was a common reason for transmission of tuberculous organisms.

Case-patient 2 shows that a patient with AIDS can have infectious tuberculosis despite a normal chest radiograph. Active pulmonary tuberculosis should be suspected in patients who have AIDS, fever, and cough, regardless of radiographic findings (10). The evidence of transmission to a patient exposed for only 23 hours underscores the urgency with which patients who have signs and symptoms compatible with tuberculosis should be immediately isolated and evaluated.

Limitations of this investigation include the possible underestimation of transmission to exposed patients as a result of a high patient mortality rate. In addition, immunosuppression among patients may have made tuberculin skin testing unreliable. Skin test results were not available for 40 of the patients who may have been exposed; however, most of these patients were not known to have HIV infection, and their private physicians did not consider them to be at high risk for tuberculous infection or disease. The number of exposed health care workers who became infected without directly caring for a patient with tuberculosis may have been overestimated because chart signatures and assignment sheets may have been incomplete. Information is lacking for health care workers who resigned from the hospital or did not complete the questionnaire. Use of respirators may have been overestimated as a result of self-reporting.

As of 1993, 38% of hospitals in the United States reported not having acid-fast bacilli isolation rooms consistent with guidelines from the Centers for Disease Control and Prevention (18). Inadequate isolation facilities and delayed diagnosis of tuberculosis may contribute to the airborne spread and nosoco-

mial transmission of *M. tuberculosis*. Germicidal ultraviolet irradiation may be used as a supplemental environmental control measure to reduce the concentration of infectious droplet nuclei in the environment (10). The excellent skin testing program in this hospital facilitated the detection of new infections. A respiratory protection program alone cannot protect all health care workers from infection with *M. tuberculosis*, especially those who work on the wards but do not enter patient rooms. Hospital infection control programs should emphasize the prompt identification of patients with tuberculosis and isolation consistent with the recommendations of the Centers for Disease Control and Prevention. Although all cases of active tuberculosis in this outbreak were seen in persons with AIDS, inadequate administrative and environmental controls put all patients and hospital staff at risk for tuberculous infection and disease.

Acknowledgments: The authors thank the staff of the Chicago Tuberculosis Control Program, particularly Ms. Carla Lee, and the physicians of the exposed patients for their assistance and support. They also thank Mr. Tony Thompson of the Illinois Department of Public Health and Ms. Laura Mosher and Mr. Stephen Dietrich of the Michigan Department of Public Health for assistance with laboratory aspects of the investigation and Dr. Jennifer Lightdale for assistance with data collection.

Grant Support: In part by the Centers for Disease Control and Prevention, St. Joseph Hospital, and the Chicago Department of Public Health.

Those people who have no knowledge of ethics, who are fearful of people because of fearfulness of soul, who when struck by misfortune or disaster wail and weep, and who when they receive something good, though joy is great, given the defective education of their souls, imagine that they have received an uncommonly great good and in their pride become more arrogant. However, for those who decide in favor of ethics, their souls gain in strength. They are truly heroes, so that their souls are always slightly influenced and altered by good and evil. The more spiritual training a man has, no matter his religion or change of circumstances, then happiness or unhappiness when receiving a great good or evil is less unsettling than those who do not believe. When struck by a great happiness or unhappiness, those who have the ethical and philosophical belief are less elevated by or unsettled and therefore bear happiness or sorrow more bravely.

Nosocomial aspergillosis and building construction

DONNA HAIDUVEN

University of South Florida, College of Public Health & Center for Biological Defense, Tampa, Florida, USA

Healthcare-associated infections (HAI) with *Aspergillus* pose a serious threat to those most severely immune suppressed patients. Outbreaks of nosocomial aspergillosis have occurred mainly among neutropenic patients, but with several important exceptions. HAI due to aspergillosis has occurred in association with environmental disturbances including but not limited to: hospital construction, maintenance, demolition and renovation; contaminated fireproofing materials; air filters in hospital ventilation systems, and via contaminated carpeting. It behooves those in the practice of patient care to prevent these situations before they occur, as opposed to dealing with them once they happen. The framework of the six links in the infectious disease process will be used to examine healthcare-associated invasive aspergillosis: causative agent, portal of entry, susceptible host, portal of exit, reservoir and mode of transmission. Two particular interventions: the Protective Environment (PE), and the Infection Control Risk Assessment (ICRA), will be outlined. Building construction projects and the number of neutropenic patients are likely to continue to increase. Therefore, future directions need to focus on reducing the susceptibility of the susceptible host and reducing the exposure to *Aspergillus* from environmental sources. In addition, recently released guidelines with control measures aimed at reducing environmental exposure to *Aspergillus* need to be further studied.

Keywords nosocomial aspergillosis, healthcare-associated aspergillosis, construction, aspergillosis outbreaks, nosocomial infections

Introduction

Healthcare-associated infections (HAI) with *Aspergillus* pose a serious threat to those most severely immune suppressed patients. Outbreaks of nosocomial aspergillosis have occurred mainly among neutropenic patients, but with several important exceptions. HAI due to *Aspergillus* have occurred in association with environmental disturbances including but not limited to: hospital construction, maintenance, demolition and renovation; contaminated fireproofing materials; air filters in hospital ventilation systems, and via contaminated carpeting. The framework of the six links in the infectious disease process will be used to examine

healthcare-associated invasive aspergillosis. Two infection control measures designed to protect the severely immune suppressed form HAI due to aspergillosis, the Protective Environment and the Infection Control Risk Assessment will be described in detail. Finally, implications for the future will be presented.

Background

It is estimated that healthcare-associated infections (HAI) account for approximately 1.7 million infections and 99,000 associated deaths each year in the United States. Of these HAI: the breakdown is as follows: 32% urinary tract infections, 22% surgical site infections, 15% pneumonia, and 14% bloodstream infections [1]. It is important to note that even though pneumonia is not the most frequently occurring form of HAI, this type of HAI carries with it the highest mortality rate [2]. Fungal infections comprise 9% of all HAIs. Among fungal infections, *Candida* accounts for 85.6% and

Aspergillus 1.3% (<2%) respectively. It has also been estimated that between 1980 and 1990, 2.0–3.8%/1,000 patient discharges had HA fungal infections [2,3]. Healthcare-associated *Aspergillus* infections are most frequently due to *A. fumigatus*, *A. flavus*, and then followed by other species. Pneumonia is the most common clinical presentation for aspergillosis and therefore patients who acquire aspergillosis have a very high mortality rate. The mortality rates reported in the literature have been as high as 95% in certain cases [3,4].

It is difficult to provide a specific incidence for aspergillosis cases, as this is not one of the nationally notifiable diseases or conditions. Thus, currently no national surveillance data exists. As an example, a population-based study conducted in San Francisco, California estimated the incidence of aspergillosis to be 1–2 cases/per 100,000 persons/per year. Currently, the Centers for Disease Control is conducting active surveillance among hematopoietic stem cell transplants & solid organ transplant recipients in selected US hospitals [4].

Components of the infectious disease process in relation to healthcare-associated aspergillosis

It is important to note that healthcare-associated aspergillosis is a global problem. Numerous outbreaks have been reported in the literature from many countries [3,5]. In this section, the components of the infectious disease process and their relationship to acquisition of healthcare-associated aspergillosis will be outlined. Case examples to illustrate these components will be included.

There are six links in the chain of the infectious disease process. These are: causative agent, mode of transmission, susceptible host, portal of entry, portal of exit, and reservoir [6]. The ‘causative agent’ is defined as a biologic, physical or chemical entity capable of causing disease. In cases of healthcare-associated aspergillosis, the causative agent includes all species of *Aspergillus* that have caused infection in patients. Rather than limit the number of species, it is important to emphasize that *Aspergillus* is a fungus, ubiquitous in nature, which has been recovered from numerous environmental sources and may continue to be present as long as there are activities which disrupt it from its reservoir. The species of *Aspergillus* most frequently acting as the causative agent in 53 outbreaks of healthcare-associated invasive aspergillosis affecting 458 patients was *fumigatus* (154 cases), *flavus*

(101 patients), and no species identification was conducted in 108 cases [5].

The ‘mode of transmission’ is the mechanism of transfer of an infectious agent from a reservoir to a susceptible host. In the HAI context, despite one report to the contrary, aspergillosis is not transmissible from person to person. In one report, debridement and dressing of a wound infected with aspergillus was the documented source of airborne transmission of this pathogen between patients in a transplant intensive care unit [7]. There have been no other reports to date where person-to-person transmission resulted in cases of invasive aspergillosis. Thus, in this context, the mode of patient-to-patient transmission is not a major component in the infectious disease process on which to place focused intervention efforts to prevent healthcare-associated aspergillosis.

The ‘portal of entry’ is defined as the path by which an infectious agent enters the susceptible host. Portals of entry associated with human hosts are numerous, and similar to the portals of exit. In healthcare facilities, patients have many portals of entry and numerous opportunities for the entry of infectious agents, when the first line of defense, the skin, is entered or interrupted. When specifically examining HAI with *Aspergillus*, the portal of entry in the majority of reported cases has been through the pulmonary tract, by inhalation of conidia. [3,5]. However, there are other reports in the literature describing a different portal of entry than the pulmonary tract. One notable report was a case series from Saudi Arabia. Five cases of *Aspergillus* ophthalmitis occurred within a 3-week period coinciding with hospital construction. The outcome for all five cases was enucleation or evisceration. The authors noted that the primary period for optimal growth and multiplication of *A. fumigatus* (the causative organism in these cases) is January through March, and this cluster occurred during January and February [8].

In another report, the portal of entry was direct inoculation of *Aspergillus* spores into surgical and burn wounds of five patients. In these cases, the outside of the dressing supply packages became contaminated during construction in the central inventory control area, resulting in direct inoculation of *Aspergillus* spores into large exposed skin surfaces. [9]. In a report from Switzerland, two cases of fatal pulmonary aspergillosis occurred in patients who were intubated and mechanically ventilated after a routine air filter change had occurred in the same intensive care unit room. In these cases, it is postulated that the portal of entry was by a high inoculum of spores during mechanical ventilation [10].

This is an important aspect regarding the portal of entry for HAI *Aspergillus*. Even though the pulmonary tract has been the most common portal of entry, these other examples underscore the importance of reducing patient exposures to *Aspergillus* conidia released from environmental reservoirs.

The definition of a 'portal of exit' is the path by which an infectious agent leaves the reservoir. Portals of exit associated with human and animal reservoirs are the following: the respiratory tract, genitourinary tract, gastrointestinal tract, the skin/mucous membranes, transplacentally from mother to infant, and via blood. In a healthcare-associated situation, the portal of exit is closely related to the mode of transmission. As the majority of HAI with *Aspergillus* are not transmitted from person to person, the emphasis on focusing control measures on preventing the exit of that organism from the infected patient does not appear to a major component. The one noted exception, person-to-person transmission by the airborne route, was theorized to occur from aerosolization of a patient's wound infected with *Aspergillus species* when the wound was debrided and dressed. Aerosolization of spores from the wound was the portal of exit in this instance [7].

The 'susceptible host' is a person or animal lacking effective resistance to a particular agent. Susceptible hosts for healthcare-associated *Aspergillus* infections have included, in decreasing order of frequency, patients with hematological malignancies (in particular, allogeneic hematopoietic stem cell transplant patients (HSCT), solid organ transplants, other immune suppressed patients, and non-immune suppressed patients [5]. The majority of reports have been from HSCT patients, with high fatality rates [5]. One report described two cases of fatal invasive aspergillosis in two patients with chronic obstructive pulmonary disease but without immune suppression. Risk factors for the cases included room placement and intubation. Both patients had been in the same room and died 16 and 22 days after intubation respectively. Both had negative sputum cultures before they were intubated [10]. In the previously mentioned outbreak causing five cases of *Aspergillus* ophthalmitis, the affected cases were patients undergoing cataract surgery [8].

The 'reservoir' is a place in which an infectious agent can survive but may or may not multiply. The three most common reservoirs associated with hospital-acquired infectious agents include patients, healthcare personnel and the healthcare equipment/environment. When focusing on HAI due to *Aspergillus*, there have been numerous reports tracing the source of cases or outbreaks to construction conducted in healthcare facilities. The two main environmental sources have

included unfiltered outside air entering hospital through gaps in filters, windows, backflow of contaminated air; and moist environments (e.g., plumbing, leaks, rainwater, air conditioning condensate, etc.). However, it is important to note that there have been no reported outbreaks of *Aspergillus* traced to water sources [5].

Examples of additional areas which have served as reservoirs for HAI aspergillosis include but are not limited to the following: air filters, fireproofing materials, air conditioners, duct systems, and dust above false ceilings [10–14]. These examples illustrate the need for efforts to be undertaken to reduce the opportunities for *Aspergillus* spores to leave their reservoirs during construction and other activities which release and disperse the spores.

When outbreak investigations have been conducted, positive cultures have been found from ceiling tiles, carpet, fireproofing materials, and particleboard frames of air filters. This raises issues regarding environmental culturing for *Aspergillus*. In general, routine culturing of the environment is not recommended except in a few specific circumstances. These include monitoring of dialysis water and dialysate, infant formulas, and when implicated in an epidemiologic investigation. This culturing, when conducted, should be done in conjunction with Infection Control & the Hospital Epidemiologist [15].

Another issue with environmental cultures is determining how much *Aspergillus* is required to cause an infection. In 24/53 outbreak articles, the concentration of airborne fungi in patient care areas ranged from 0–100 spores/m³. However, even spore counts <1 cfu/m³ were sufficient to cause infection in high-risk patients [5]. This is an area requiring more investigation.

Reviewing the six links in the chain of the infectious disease process in relation to HAI aspergillosis leads to the following issues. First, as an infectious agent, *Aspergillus* species are ubiquitous in nature. The portal of entry for most cases to date has been the respiratory tract, with some notable exceptions. The portal of exit and mode of transmission have for the most part, not been as important factors in nosocomial transmission. The HSCT patient and solid organ transplant patients have been the susceptible hosts in the majority of reports. The reservoir of *Aspergillus* spores is the most problematic link in this chain, and control efforts to prevent release of the spores during activities such as construction, demolition and renovation must be emphasized. When this is unavoidable, then the most susceptible hosts need to be protected in the healthcare environment.

Control measures

It is clear up to this point, that environmental reservoirs of *Aspergillus* disturbed during periods of construction, demolition and renovation have been suspected as the source in numerous case and outbreak reports in healthcare facilities. Control measures that have been used to reduce risk of healthcare associated aspergillosis have included high efficiency particulate airflow (HEPA) filter air purifiers, application of copper-8-quinolinolate (fungicide for non-porous construction materials), sealing windows, replacement of dust-accumulating horizontal blinds with vinyl, roller-type blinds, and systematic and regular surface cleaning (eliminating upholstered furniture and carpets) [15,16]. One study from Canada had, as its goal, to determine the incidence of aspergillosis in patients with leukemia or bone marrow transplants during a construction-associated outbreak and the effect of environmental control program on the incidence of aspergillosis. Thirty-six cases of healthcare-associated invasive aspergillosis occurred from January 1988 through September 1993. The incidence density preconstruction was 3.16/1000 days at risk. During construction activity before control measures were initiated, the incidence density increased to 9.88/1000 days at risk. When control measures were started and continued during the construction period, the incidence density decreased to a pre-construction level, to 2.91/1000 days at risk [17]. In a retrospective cohort study from a cancer center in the USA, 10(18%) of 55 hematology unit patients admitted from July to December 1992 were diagnosed as having invasive aspergillosis with *A. flavus* as compared with 0(0%) of 36 from January to June 1992 in the same unit. High air counts of *Aspergillus* conidia in a neighboring unit were considered to be the source of the cases. Once high efficiency particulate air filtration was added to the ventilation system of the hematology unit, there were only 2 more nosocomial aspergillosis cases in the 2 years after this outbreak. [18].

Protective environment

In 2003 and then again in 2007, the Centers for Disease Control and Prevention have recommended an infection control strategy to reduce the risk of healthcare-associated aspergillosis. This strategy is termed the 'Protective Environment' (PE) [15,19]. This recommendation applies only to acute care hospitals that provide care to hematopoietic stem cell transplant (HSCT) patients. Included in the PE recommendation are single-patient rooms, specific ventilation requirements,

and increased cleaning frequency to decrease dust accumulation. The 2007 guideline recommends respiratory protection (such as an N-95 particulate respirator) for HSCT patients, who are medically fit, when leaving the Protective Environment during periods of construction [19].

It is interesting to note the evolution of the Protective Environment concept. In the 1970s, the CDC first introduced a category of isolation called 'Reverse Isolation'. This required use of an aseptic environment, protective apparel for all entering the room, and special ventilation. In their next two guideline revisions 1983 and 1996, the category was removed altogether with the caveat that studies had not demonstrated the effectiveness of this category in reducing nosocomial infections. Reports of numerous outbreaks of nosocomial aspergillosis infections and their links to hospital construction and renovation were responsible, in part, for the latest term 'Protective Environment' which applies to a specific type of immune suppressed patient group, those with hematopoietic stem cell transplants [15,19]. The CDC states that there are no published reports to support the use of a Protective Environment for either solid organ transplant patients or other immune suppressed patients [19]. The numerous recommendations have varying categories, from IA to II, depending upon what types of studies can support them and /or whether there is a strong theoretical rationale or panel of experts to support them. This is an area with need for further investigation to determine the effectiveness of specific recommendations in reducing healthcare-associated aspergillosis.

Infection control risk assessment

An additional infection control strategy is the Infection Control Risk Assessment (ICRA). The ICRA is a multidisciplinary process focusing on reducing risk from infection throughout facility planning, design, and construction (including renovation) activities. A multidisciplinary team considers the environment, infectious agents, human factors and the impact of the proposed project in this process. The ICRA is a step-by-step process that begins with identifying the type of construction project activity, assessing the at-risk patient population and concludes with determining infection control recommendations for each class of activity rated A-D. The ICRA is part of the American Institute of Architects' *Guidelines for Design and Construction of Health Care Facilities* [20].

Even though designed as guidelines, the Joint Commission for the Accreditation of Healthcare Organizations (JCAHO), in their Environment of Care

Table 1 Levels of infection risk, from low to high, according to hospital department/unit [22].

Low risk	Medium Risk	High Risk	Highest Risk
Office areas	Cardiology Echocardiography Endoscopy Nuclear Medicine Physical Therapy Radiology/Magnetic Resonance Imaging Respiratory Therapy	Critical Care Units Emergency Department Labor & Delivery Laboratories Newborn Nursery Outpatient Surgery Pediatrics Pharmacy Post Anesthesia Care Unit Surgery Units	Any area with immune-suppressed Burn Unit Cardiac Cath Lab Central Sterile Supply Intensive Care Unit Medical Unit Negative Pressure Isolation Room Oncology Operating Rooms (including C-Section)

section, requires that the ICRA be followed by all healthcare facilities. In addition to these guidelines, JCAHO requires daily logs to be kept during the construction projects (including weekends and holidays) and that facilities comply with the AIA guidelines. Therefore, if a healthcare facility wishes to receive JCAHO accreditation, these guidelines must be followed [21].

There are four steps in the ICRA process. Step One is to identify the type of construction project activity. There are four categories of construction project activity ranging from A–D. Type A activities are those that are non-invasive, including, not limited to: (i) removal of ceiling tiles where no dust is expected, (ii) painting without sanding, and (iii) wall covering, electrical trim work, minor plumbing, and activities which do not generate dust or require cutting of walls or access to ceilings other than for visual inspection. The important condition for an activity to fit into Category A is that it does not produce any dust. Type B activities include small scale, short duration activities that create minimal dust. Examples include: (i) installation of telephone and computer cabling, (ii) access to chase spaces, and (iii) cutting of walls or ceilings where dust migration can be controlled. The key to being categorized as a Type B activity is a project of short duration where minimal dust is produced. Type C Activities include work generating moderate to increased level of dust or requires demolition/removal of any fixed building components. Examples include but are not limited to (i) sanding of walls for painting/

wall covering, (ii) removing floor coverings, ceiling tiles, and casework, and (iii) new wall construction. Type C also includes any activity which cannot be completed in a single work shift. Type C activities are dust generating and/or of longer duration. Type D Activities apply to major demolition and construction projects, including renovation. Examples of Type D activities include those requiring heavy demolition or removal of a complete cabling system or new construction. The key to type D is that this includes major demolition or construction [22].

Step Two in the ICRA process is to identify the patient risk group that will be affected (see Table 1). If more than one risk group is affected, the higher group should be selected. It is important to mention that for all construction classes, the patient must be removed from the room while work is performed [22].

Step Three is to match the patient risk group (Low, Medium, High, and Highest) with the construction project type (A, B, C, D) to find the class of precautions (I–IV) that need to be followed (see Table 2). To determine the class of precautions required during a particular project, select the risk group, and then follow it to the corresponding project type. The classes of precautions are the levels of infection control activities required to be followed during the particular project.

To illustrate how this process works, suppose there needs to be a new computer system installed in the Nuclear Medicine Department. This job will require three days to complete. Thus, this is a Type C activity.

Table 2 Matrix of project category type, patient risk group and class of required infection control precautions [22].

Patient Risk Group	Project Type A	Project Type B	Project Type C	Project Type D
LOW Risk	Class I	Class II	Class II	Class III/IV
MEDIUM Risk	Class I	Class II	Class III	Class IV
HIGH Risk	Class I	Class II	Class III/IV	Class IV
HIGHEST Risk	Class II	Class III/IV	Class III/IV	Class IV

The Nuclear Medicine Department is a medium risk area. Given this information, one can determine that Class III precautions need to be followed for this project.

Conclusion

Building construction projects and the number of neutropenic patients are likely to continue to increase in number, thus augmenting the risk and occurrence of healthcare-associated aspergillosis. It is also possible that advances in technology may require neutropenic patients to remain in protective environment for longer than the 100 days currently necessary. Such patients must be protected from infections. Based upon an analysis of the infectious disease process in relation to healthcare-associated *Aspergillus* infections, future directions need to focus on reducing the susceptibility of the host and reducing the exposure to *Aspergillus* from environmental reservoirs. Future research questions may need to include how to detect the smallest numbers of colonies in the environment, how to make additional materials fungicidal, how to make patients non-neutropenic and the potential for vaccines against *Aspergillus*. Investigators in this field are encouraged to review research that has been conducted with a critical eye and contribute to future study designs. It behooves those in the practice of patient care to prevent aspergillus infections before they occur, as opposed to dealing with them once they happen. Recently released guidelines, such as the Protective Environment and the Infection Control Risk Assessment, take this proactive approach, with control measures related to reducing environmental exposure to *Aspergillus* spores by susceptible patients. However, these measures need to be further studied for their effectiveness in reducing healthcare-associated aspergillosis.

Grading scheme for recommendations used in *M. abscessus*

The criteria for the grading of recommendations in this document are based upon a paper by Petrie et al (1995) published on behalf of the Scottish Intercollegiate Guidelines Network.

Much of the data in the document is derived from observational studies where randomisation is not appropriate or possible, however a lot is also from peer reviewed scientific studies. The above grading is therefore not always appropriate.

Levels of evidence

Level	Type of evidence (based on AHCPR, 1992)
Ia	Evidence obtained from meta-analysis of randomised controlled trials.
Ib	Evidence obtained from at least one randomised controlled trial.
IIa	Evidence obtained from at least one well designed controlled study without randomisation.
IIb	Evidence from at least one other type of quasi-experimental study.
III	Evidence obtained from well-designed, non-experimental, descriptive studies, such as comparative studies, correlation studies or case control studies.
IV	Evidence obtained from expert committee reports or opinions and/or clinical experience of respected authorities.

Grading of recommendations

Grade	Type of recommendation (based on AHCPR, 1992)
A (levels Ia, Ib)	Requires at least one randomised controlled trial as part of the body of literature, of overall good quality and consistency, addressing the specific recommendation.
B (levels IIa, IIb, III)	Requires availability of well conducted clinical studies but no randomised clinical trials on the topic of the recommendation.
C (level IV)	Requires evidence from expert committee reports or opinions and/or clinical experience of respected authorities. Indicates absence of directly applicable studies of good quality.

Summary of main recommendations

- All cystic fibrosis (CF) services must have a local infection control guideline that addresses *M. abscessus*.
- All CF services must routinely screen for non-tuberculous mycobacteria (NTM) and forward *M. abscessus* isolates to an appropriate reference laboratory for sub-speciation and strain typing.
- All patients with *M. abscessus* colonisation/infection must be segregated.

1. Introduction

This document provides guidance on infection control measures for *Mycobacterium abscessus* in cystic fibrosis. A separate working group (jointly representing the European Cystic Fibrosis Society and North American Cystic Fibrosis Foundation) has published guidelines on screening and treatment for non-tuberculous mycobacteria (NTM).¹ Guidance from the British Thoracic Society on the diagnosis and management of NTM is also available.²

2. Background

Recent research has found evidence for cross-infection by *M. abscessus*.³⁻⁵ Cross-infection outbreaks have been reported at a US CF centre involving five patients³ and at a UK CF centre involving 11 people with CF, despite having infection prevention policies and guidelines based on best practice at the time.⁴ Another UK study found no clear evidence of direct cross-infection.⁶ A study published in 2016 provided evidence of shared strains of *M. abscessus* species among patients with CF across a number of CF centres worldwide.⁵ At present, the mode of transmission is unclear.

At the US CF centre that reported the cross-infection outbreak, no further new cases were detected after implementation of infection control measures comprising staff and patient education, environment sterilisation and patient isolation.⁷

A suspected *M. abscessus* outbreak was reported involving 9 of 19 patients at a joint adult/paediatric clinic in Hawaii. The source of the outbreak was not identified but an investigation revealed potential issues with adherence to local infection control guidance for cleaning and maintenance of shared equipment, including bronchoscopes and spirometers.⁸

Data from the UK CF Registry show that the prevalence of *M. abscessus* colonisation/infection has remained relatively static between 2014 and 2016 (table 1).⁹

Table 1

	2014 (n=9532)	2015 (n=9587)	2016 (n=9695)
<i>M. abscessus</i> prevalence	300 (3.1%)	321 (3.3%)	337 (3.4%)

Specialist CF care has been shown to be beneficial, with improved clinical outcomes for people with cystic fibrosis.^{10, 11} Avoiding clinic attendance due to concerns about *M. abscessus* infection is likely to be harmful as it may seriously interfere with medical care, which will far outweigh any potential risk of acquiring *M. abscessus* infection.

3. Definition of patients with *M. abscessus* colonisation/infection for the purpose of infection control measures

A patient is defined as having *M. abscessus* colonisation/infection if they fall in to one or more of the following groups.

1. Patients who have had *M. abscessus* isolated from sputum or bronchoalveolar lavage (BAL) cultures within the last 12 months (whether or not they are symptomatic for *M. abscessus* infection).
2. Patients who are currently prescribed treatment for *M. abscessus*.
3. Patients who have completed treatment for *M. abscessus* within the last 12 months.

For the above patients to be subsequently considered free of *M. abscessus*, quarterly sputum samples must have tested negative for mycobacteria when a patient is not receiving treatment, with an interval of one year between the first negative sample and last negative sample. For instances where sputum cannot be obtained, a negative BAL one year off treatment would suffice.

Current evidence suggests that in applying infection control recommendations there should be no distinction between smear positive and smear negative cases of *M. abscessus* colonisation/infection.⁴

3.1 Recommendations

- The patient should be kept informed of their infection status [C].
- If subsequent sputum samples become negative for *M. abscessus*, the patient should still be regarded as a potential carrier from the date of the first negative sample for a total of at least twelve months. A minimum of four negative sputum samples are required during this twelve-month period, with the final negative sample at least twelve months after the first negative sample. For instances where sputum cannot be obtained, a negative BAL one year off treatment would suffice [C].
- For infection control, there should be no distinction between smear positive and smear negative cases of *M. abscessus* colonisation/infection [C].

4. Screening of patients with CF for *M. abscessus* infection

Screening for NTM is an important part of the care of patients with cystic fibrosis. The US Cystic Fibrosis Foundation/European Cystic Fibrosis Society consensus guidance¹ on NTM screening for people with cystic fibrosis is published and accessible via this link:

http://thorax.bmj.com/content/71/Suppl_1.toc.

4.1 Recommendations

- Routine screening for NTM is recommended at least once a year for all individuals able to produce sputum, with microbiological processing of samples [C].
- Cough swabs should not be used [C].
- Consider induced sputum or BAL for patients unable to produce sputum at will (where there is clinical suspicion of infection) [C].
- For CF centres where cross-infection with *M. abscessus* is suspected, more frequent sampling for NTM should occur [C].
- All *M. abscessus*-positive patients must have an isolate referred to the appropriate reference laboratory for sub-speciation and strain typing [C].

5. Preventing spread

The mode of transmission of *M. abscessus* in cross-infection outbreaks is unclear. General infection control measures should be adhered to.¹¹

5.1 Recommendations

- Each CF service must have its own local infection control guideline that covers *M. abscessus* and its use by regular audit is recommended [C].
- The specialist CF centre/CF clinic and local infection control team should know the incidence and prevalence of *M. abscessus* in their CF population [C].
- Current inpatient and outpatient facilities should be evaluated for their present air exchange and air flow and measures taken to optimise this wherever possible [C].

- Patients with CF with *M. abscessus* colonisation/infection must be segregated from each other and from all other people with cystic fibrosis. The methods used to segregate patients should be determined by local guidelines and must take into account communal areas such as pharmacy and radiology [C].
- CF centres should educate staff, patients and visitors in the need to adhere to cross infection prevention measures within all areas of the CF centre and the wider, communal areas of the hospital [C].
- A high standard of hygiene should be practised by staff, in particular hand washing; alcohol gels or other suitable preparations must be available in every room [C].
- If CF clinics suspect they have cross-infection with *M. abscessus*, advice from the local infection control team should be sought [C].
- Patients must be seen in well-ventilated rooms [C].
- Rooms must be left with the door closed, with at least an hour (amended depending on knowledge of air flow/exchange) between patients to allow for dispersion of possible airborne contamination and then cleaned according to local infection control guidelines [C].
- Gloves and aprons/gowns must be worn and hand washing with soap and water must be performed before and after contact with each patient with *M. abscessus* colonisation/infection and/or their immediate environment [C].
- Staff may wish to wear masks when in contact with patients with *M. abscessus* colonisation/infection. There is currently insufficient evidence to recommend the routine use of masks by healthy staff. Staff should follow local policies [C].
- Patients may wish to wear masks. There is currently insufficient evidence to recommend the routine use of masks by patients, but local policies should be followed [C].
- Patients must wash their hands with soap and water before use of a spirometer or other handheld apparatus [C].
- Spirometry should be performed in the patient's own room. Other respiratory function tests should be performed in a well-ventilated room away from other patients [C].
- Collection of respiratory samples must take place in the patient's own room [C].
- Sputum pots should be covered and soiled tissues must be disposed of in the clinical waste bin immediately after use. Sputum should not be expectorated down toilets, sinks, washbasins or in showers [C].
- Airway clearance techniques and any other physiotherapy procedures must be carried out in the patient's own room [C].
- Equipment must be single-patient use where possible [C].
- Patients should be encouraged to use their own possessions and equipment in hospital [C].
- All other equipment and surfaces must be cleaned and dried between patients, according to local infection control guidelines [C].
- After a room is vacated by a patient with *M. abscessus* colonisation/infection it should undergo terminal cleaning as per local hospital guidance [C]. An example from the CF centre in Papworth can be found in **Appendix 1**.
- Inpatients should have well-ventilated single rooms with their own bathroom. Negative pressure rooms should be used where available [C].
- Exercise should be performed in a patient's own room with the door closed and any equipment appropriately decontaminated after use. If exercise is performed in a communal area this must be on an individual basis, at the end of the day and the room terminally cleaned after use [C].
- Disinfection of bronchoscopes, irrespective of the purpose they are used for, should comply with the national policy 'Management and decontamination of flexible endoscopes (HTM 01-06)' [C]. The policy is accessible via this link: <https://www.gov.uk/government/publications/management-and-decontamination-of-flexible-endoscopes>.

6. Future recommendations for cystic fibrosis clinic facilities

6.1 Recommendations

- Any new facilities for patients with CF must take into account the potential for cross-infection with *M. abscessus*. This must include the provision of enhanced ventilation for both inpatient and outpatient care and adequate ventilation in other areas [C].
- Any new facilities should consider the space required for integration of exercise equipment into inpatient rooms [C].

Appendix 1: Example of terminal cleaning protocol from Papworth Hospital

Stage 1	<i>M. abscessus</i> + ve in-patient (LOS 1 night +) plus post bronchoscopy day cases and any patients isolated with pink precautions*	Ambulatory <i>M. abscessus</i> care episode (no overnight stay) CTBI*
	Nursing staff Dispose to clinical waste any disposable items/ items that cannot be cleaned.	Ventilate the room as soon as the patient vacates the room (open door and window)
	Dispose of any bed linen into red water soluble bag and then into a white plastic laundry bag.	Nursing staff Dispose to clinical waste any disposable items/ items that cannot be cleaned.
	Domestic staff/PEA Dispose to orange bag (offensive waste stream) any disposable curtains from room.	Domestic staff/PEA Dispose to orange bag (offensive waste stream) clinical waste/curtains from room.
	Leave room for an hour before taking any further action.	Ventilate the room for one hour prior to cleaning.
Stage 2	Nursing staff Wearing Personal Protective Equipment (long-sleeved gown, gloves, surgical mask, eye protection) and taking care not to splash, use bottle brush or sponge stick to clean sink and shower outlets ensuring all visible gunk rinsed away. Flush shower and sink outlets with tap water for five minutes.	Nursing staff Use a chlorine based product (Tristel™ product, with the appropriate contact time as provided by the manufacturer) to clean all surfaces and medical equipment.
Stage 3	Nursing staff Use a chlorine based product (Tristel™ product, with the appropriate contact time as provided by the manufacturer) to clean all surfaces and medical equipment.	Domestic staff/PEA Complete final exit clean.
Stage 4	Domestic staff Complete final exit clean	
Stage 5	Nursing staff Contact ISS through operational support to arrange HPV clean.	Re-introduce room for clinical use.
Stage 6	Nursing staff If the room is being swabbed please contact trained nursing staff for environmental sampling.	
Stage 7	Re-introduce room for clinical use

Preface

About Health Technical Memoranda

Health Technical Memoranda (HTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of Health Technical Memorandum guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle.

main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of nine subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering, technology and sustainability;
- provides a structured reference for healthcare engineering.

Figure 1 Healthcare building life-cycle

Healthcare providers have a duty of care to ensure that appropriate governance arrangements are in place and are managed effectively. The Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

It is not the intention within this suite of documents to unnecessarily repeat international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Health Technical Memorandum guidance is the

Structure of the Health Technical Memorandum suite

The series contains a suite of nine core subjects:

Health Technical Memorandum 00

Policies and principles (applicable to all Health Technical Memoranda in this series)

Health Technical Memorandum 01

Decontamination

Health Technical Memorandum 02

Medical gases

Health Technical Memorandum 03
Heating and ventilation systems

Health Technical Memorandum 04
Water systems

Health Technical Memorandum 05
Fire safety

Health Technical Memorandum 06
Electrical services

Health Technical Memorandum 07
Environment and sustainability

Health Technical Memorandum 08
Specialist services

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Health Technical Memorandum 06-02 represents:

Electrical Services – Electrical safety guidance for low voltage systems

In a similar way Health Technical Memorandum 07-02 represents:

Environment and Sustainability – EnCO₂de.

All Health Technical Memoranda are supported by the initial document Health Technical Memorandum 00 which embraces the management and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.

DH Estates and Facilities Division wishes to acknowledge the contribution made by professional bodies, engineering consultants, healthcare specialists and NHS staff who have contributed to the production of this guidance.

Figure 2 Engineering guidance

Executive summary

During 2002/2003, the NHS in England consumed 40.3 million cubic metres of water and produced 34.4 million cubic metres of sewage. This comes at a cost – not just financial, but at a cost to the environment.

Financial savings of up to 20% may be achieved through water-efficiency measures, with little or no cost in investment. This translates to a possible saving of £9.5 million per year.

Much of these savings can be immediately realised through minor repairs to existing infrastructure and through staff behaviour, while others may require an initial capital investment that can be recovered within a specified payback period.

This Health Technical Memorandum encourages investigating these possible savings. Its principal remit is

to encourage the efficient management of water and to promote the economic and environmental benefits of doing so. Additionally, it examines water-management decisions in the context of:

- patient health and well-being;
- social and behavioural aspects; and
- available and appropriate technology.

Methods for auditing facilities are outlined, with common areas of high water use discussed and technical solutions proposed. Guidance on establishing necessary social and behavioural aspects such as staff awareness, appropriate use of technology and a clear definition of responsibilities are also outlined.

1 Introduction

1.1 This guidance document lays out the steps to developing a water strategy for healthcare facilities. Its principal remit is to encourage the efficient management of water and to promote the economic and environmental benefits of doing so. Additionally, it examines water-management decisions in the context of:

- patient health and well-being;
- social and behavioural aspects; and
- available and appropriate technology.

It is relevant to all healthcare facilities, not just hospitals.

1.2 The document refers to national or NHS policy and guidelines where appropriate, outlining a comprehensive approach to water management (see Figure 1).

1.3 Methods for auditing facilities are outlined, with common areas of high water use discussed and technical solutions proposed. Guidance on establishing necessary social and behavioural aspects such as staff awareness, appropriate use of technology and a clear definition of responsibilities are also outlined.

Action checklist

1.4 The following table is a summary of actions and their associated savings in terms of water and costs. It is not an exclusive list, but rather represents a first glimpse of how water savings can be accomplished. These items are discussed in more detail in [Chapter 6](#).

Figure 1 Efficient water management in context

Item	Typical percentage of total healthcare consumption	Typical consumption rate	Potential actions
WCs	24	6–9 L flush	• Install a cistern displacement device – saving approximately 1 L per flush • Retrofit to a dual flush or lower flush system – giving the option for a half flush. (Note: Where dual-flush toilets are specified, they should have guidance or symbols instructing the user on the appropriate operation of the flushing device) • Replace old WCs with those that give a flush volume of up to 6 L (maximum)
Urinals	5	500–900 L per day	• Controlled flushing through foot triggers or motion sensors can reduce consumption by 120–200 L per day • Waterless urinals
Taps	13	400 L per day	• Flow restrictors, non-concussive self-closing taps and sensor^a taps can reduce consumption by up to 50% (Note: the choice of tap should be appropriate for the intended use)
Leak detection	15–30	Small leak: 6 L per hour Large leak: 400–800 L per hour	Inspect all fixtures and fittings, graph monthly bills, or conduct internal monitoring through submetering to identify possible leaks
Boiler	Variable	Intense energy consumption means costs are much higher than water alone	• Adjust boiler blowdown amount and frequency to reduce waste and to control total dissolved solids (TDS) • Collect and reuse steam condensate • Control steam losses

See Health Technical Memorandum 00 for guidance on recommended sanitary assemblies in healthcare facilities.

Also refer to the compliance criteria in BREEAM Healthcare.

^a Automatic or sensor taps will only be effective when properly maintained and kept in good working order.

2 Managing water wisely in healthcare facilities

Water resources in the UK

- 2.1 The UK's water resources are coming under increasing pressure. There is a risk that demand might exceed the total amount of water that can be abstracted from rivers and underground supplies, a situation that could lead to environmental damage and degradation. The Environment Agency has estimated that many aquifers are already over-abstracted. (Figure 2 summarises the water resource availability for each catchment in England and Wales.)
- 2.2 In highly urbanised regions such as southern England, the natural environment is now seriously under threat from water abstraction. For some areas of the South East, the availability of water per head has grown sufficiently serious to be comparable with that of some Middle-Eastern countries. There is a need, therefore, to relieve pressure by implementing better and more informed water-management strategies.
- 2.3 In addition to growing pressures on water resources from housing and commercial development,

Figure 2 Water resource availability for England and Wales

climate change will significantly alter the way the UK uses its water resources, as well as the nature of water resources themselves. Summers are projected to become hotter and drier, and winters wetter. Accompanying this change in seasons will be an increased incidence and intensity of droughts and floods. Water will therefore be a crucial aspect of climate-change adaptation.

- 2.4 Furthermore, water use has a direct association with climate-change mitigation. Significant amounts of energy are used in the supply and treatment of water. Water UK (2007) estimates place the carbon costs of water supply at around 0.271 grams of CO₂ per litre, a figure likely to be much higher if the water is heated. Therefore, a more efficient use of water in healthcare facilities could result in a significant reduction of their carbon footprint.
- 2.5 In the context of increased development, climate change and limited water resources, the Department for Environment, Food and Rural Affairs (Defra) has observed that maintaining a reliable supply of water is no longer uniquely the remit of water suppliers. Measures need to be taken on the part of those using water to improve efficiency (Defra, 2007).

Social responsibility and sustainable development

- 2.6 The NHS has the largest and most complex estate portfolio in Europe. These estates will have an impact on their surroundings, be it in terms of culture, economy or the environment.
- 2.7 Managing water efficiently across the healthcare estate will require a wide range of approaches and will ultimately have a large impact on the healthcare sector's environmental footprint.
- 2.8 A clear and ambitious water strategy (see [Chapter 5](#)) will not only help to mitigate the environmental impacts of healthcare facilities, but will also serve to promote the sustainability of those facilities to those who use them and to the wider public.

Refer also to:

- BREEAM Healthcare;
- The Good Corporate Citizenship model.

3 Legislative and policy-related responsibilities

3.1 In addition to Defra's broad twin-track policy on water resources (Defra, 2008), a mounting volume of national and international policy and legislation specifically calls for actions to be taken to improve water efficiency and management.

European policy and legislation

3.2 The European Commission's communication on drought and water scarcity (COM (2007) 414 final) estimates that 20% of all water consumed in the EU is wasted and states that:

"Water saving must become the priority and all possibilities to improve water efficiency must therefore be explored."

3.3 The Water Framework Directive (2000/60/EC) sets out requirements and measures to improve water efficiency.

3.4 The Integrated Pollution Prevention and Control (PPC) Directive (96/61/EC) has now been transposed into law by the Pollution Prevention and Control Act 1999 and the Pollution Prevention and Control (England and Wales) Regulations 2000 (as amended).

National policy and legislation

Water Act 2003

3.5 The Water Act 2003 established that it is the responsibility of all public bodies to conserve water.

3.6 The Act also:

- introduced time limits for all new abstraction licences;
- introduced the facility to revoke abstraction licences that cause serious environmental damage;

- introduced greater flexibility to raise or lower licensing thresholds;
- deregulated small and environmentally insignificant abstractions;
- extended licensing to abstractors of significant quantities presently outside the licensing system.

3.7 The Environment Agency is developing catchment abstraction management strategies (CAMS) that aim to provide a structured approach to local water resources management, recognising the reasonable needs of abstractors and the needs of the environment. This fits in with the needs of the Water Framework Directive (2000/60/EC) mentioned in paragraph 3.3. The Environment Agency assesses any new application for a licence against the CAMS.

In Scotland, the Scottish Building Standards Agency has issued guidance on water use and efficiency.

In Northern Ireland, under the Water Act (Northern Ireland) 1972, the Environment and Heritage Service (EHS) is required to promote the conservation of the water resources of Northern Ireland and to promote the cleanliness of water in waterways and underground strata.

Water Supply (Water Fittings) Regulations 1999

3.8 All water fittings are covered by the Water Supply (Water Fittings) Regulations 1999 for England and Wales. This legislation includes information on the water use of individual appliances.

3.9 Implementation of the Regulations is overseen by the Water Regulations Advisory Scheme (WRAS).

Note

In England and Wales, the Water Supply (Water Fittings) Regulations and the Building Regulations are to be updated to include greater emphasis on water efficiency.

In Scotland, water fittings are covered by the Water Byelaws (2004).

In Northern Ireland, water fittings are governed by the Water Regulations (Northern Ireland) 1991. The Water and Sewerage Services (Miscellaneous Provisions) (Northern Ireland) Order 2006 introduces provisions relating to information sharing in connection with water and sewerage charges and introduces controls on the abstraction and impounding of water.

- 3.11 Defra's (2008) current water strategy cites water efficiency as playing a prominent role in achieving a sustainable supply–demand balance, and encourages industrial and commercial sectors to lead by example through initiatives such as voluntary agreements.

Code for Sustainable Homes

- 3.12 All new public-building developments are subject to obligatory water efficiency benchmarks as defined in the 2006 Code for Sustainable Homes. It is likely that a non-domestic version of the Code will be produced in the next two years.

A list of regulators and other independent bodies involved in water management is given in [Chapter 9](#).

Water strategy

- 3.10 The Government has set a target of a 25% reduction in water use in its office and non-office estates by 2020, relative to 2004/2005 levels (Defra, 1999).

4 Economic benefits

- 4.1 It is likely that the trend of emerging policy and legislation with regard to water efficiency and management will continue, as will increases in water prices. In highly stressed areas, restrictions on water use may be enforced more frequently during drought periods. Acting sooner rather than later will establish standards of water management and reporting, which pre-empt these changes and limit the associated risks to healthcare services.
- 4.2 During 2002/2003, the NHS in England consumed 40.3 million cubic metres of water and produced 34.4 million cubic metres of sewage. Healthcare estates are likely to be classified as non-domestic and charged through a combined flat rate and a volumetric rate, the flat-rate portion being determined by the size of the supply pipe and/or meter entering the property. This Health Technical Memorandum encourages investigating the possible savings that can be achieved not only through a reduction in the volume of water consumed, but possibly through a downsizing of supply pipes and/or meters in order to match the reduced consumption.

Note

The Water Services Regulation Authority (Ofwat) has published proposals to change the water supply licensing (WSL) regime to extend competition in the water and sewerage industry. The aim is to deliver economic as well as environmental benefits. Visit Ofwat's website for more information.

Potential savings

- 4.3 Water UK (2003) estimated that, in total, financial savings of up to 20% may be achieved through water-efficiency measures in healthcare estates, with little or no cost in investment. This translates to a possible saving of £9.5 million per year (at 2001 prices).
- 4.4 Much of these savings can be immediately realised through minor repairs to existing infrastructure and through staff behaviour, while others may require an initial capital investment that can be recovered within a specified payback period.
- 4.5 Some types of water-efficiency activity will also incur savings in energy costs, as less water is required to be heated.

Reducing water waste and its associated savings

- 4.6 The following examples show the types of measure – and their associated savings – that can be taken to reduce water consumption. They are examples of practical actions that have been used in the healthcare sector.
- 4.7 Examples 1 and 2 show how large savings can be made with very little capital expenditure and no actual or perceived impact on hygiene. Examples 3 and 4 show that large savings can be made with payback periods of a couple of years, if more money is invested. In addition, example 4 shows that action can be taken in clinical areas without compromising hygiene.

Note

Other actions to save water may be more appropriate for different estates, and a choice of the best action to take can only be made after a preliminary audit.

Example 1: identifying leaks

It was estimated that 15–30% of hospital consumption could be attributed to leakage. A small leak was potentially found to lose around 6 L per hour, leading to the loss of 53 m³ per year. More significant leaks were found to potentially lose up to 3500–7000 m³ per year, costing approximately £6400 a year. After identifying and repairing two major leaks, one NHS hospital reported savings of £100,000 a year (source: Water UK, 2003).

Example 2: urinal flushing

Public urinals in one hospital were set to flush automatically every 20 minutes and retrofitted with water-saving devices, which limit unnecessary flushes. Each fitting cost £120 per unit, saving £234 of water each year, resulting in a six-month payback period (source: Water UK, 2003).

Example 3: steam traps

South Manchester Hospital Trust installed a low-maintenance steam-trap system to conserve water. The cost of the project was £24,000, saving £1750 a year on water costs and £8600 on energy costs. The payback period was around 28 months (source: Carbon Trust, 2000).

Example 4: wastewater recycling

East Kent and Canterbury Trust made huge savings in its renal unit. A significant amount of wastewater was produced by the hospital's reverse osmosis plant. The project installed holding tanks and pipework that allowed the wastewater to be reused for urinal and WC flushing in the main operating theatres and the emergency care department, topped up with mains water when needed. The project reduced mains water consumption by 33%, saving £7000 a year. This allowed for project costs to be recovered in less than three years (source: Environment Agency, 2005).

5 Developing a water strategy

- 5.1 The best way to approach water management within any site or building is to develop a strategic plan. One of the main aspects of a water strategy is water efficiency, but it should be much wider than that, encompassing all water issues. The strategy should cover everything from flooding to hygiene – even if specific sections just state that the issue is covered elsewhere. The aim is to act as a central reference for all water issues.
- 5.2 A water strategy will not be static; rather it will be a continuous process of monitoring, adaptation and implementation, which feeds into a live document (see Figure 3). The process can be entered at any stage, depending on where the site/building is with regard to water management. However, it is recommended that the first step is an audit.

Figure 3 The water strategy process

Establishing and maintaining a framework of management

- 5.3 In developing a water strategy, stakeholders from various organisational levels should be involved (see Figure 4).

Senior management

- 5.4 In preparation for developing a water strategy, the issue of water management should be raised at a senior management level and support secured. Senior management should also discuss the possibility of integrating water-efficiency goals into key performance indicators.

Water champions

- 5.5 Senior management should designate a water champion and provide the necessary resources and powers to conduct a water audit and coordinate the

water strategy. Champions will act as coordinators for implementation, sources of information and a channel for reporting to senior management.

Staff involvement

- 5.6 Water is often misconceived as effectively limitless and costless. Efficient management is hampered by a lack of staff awareness, leading to potential savings in water bills and increased environmental integrity being overlooked in the past.
- 5.7 The development of a water strategy should be seen as an opportunity to raise staff awareness as well as to gather input.
- 5.8 Water use is an emotive issue, and staff should be informed of the project to develop a water strategy and be given regular information during the process.

Figure 4 Framework of responsibilities for water management

- 5.9 The development of the strategy should also, where possible, be an interactive process with adequate provision for staff to comment or contribute to the strategy. All staff will have a view on water, but the strategy should particularly involve those who use water in their duties or would be affected by the strategy.
- 5.10 Daily routines should be investigated to identify patterns of water use.
- 5.11 Finally, it may be of particular significance to discuss changes in water management with medical, nursing and infection-control staff in order to ensure that all parties are satisfied that there is no compromise to clinical care, hygiene or infection control.

Building management systems

- 5.12 A building management system (BMS) is a computer-based centralised procedure that helps to manage, control and monitor certain engineering services within a building or a group of buildings. If used appropriately, such a system ensures efficiency and cost-effectiveness in terms of labour and energy costs, and provides a safe and more comfortable environment for the building's occupants.
- 5.13 A BMS is operated from a central station, usually a personal computer, from which the user is able to analyse updated monitor values received from outstation sensors, actuators and stand-alone controllers.
- 5.14 With the installation of water submeters, temperature sensors and reporting procedures at key points in a building, a BMS may support water management through the following:
- monitoring of water consumption and the identification of leaks or excessive consumption (see [paragraphs 5.27–5.39](#));
 - monitoring of water temperature for health and safety reasons (see [paragraphs 5.25–5.26](#) and [paragraphs 7.22–7.30](#));
 - management of boilerhouses and cooling-tower cycles and maintenance (see [paragraphs 6.1–6.14](#));
 - scheduling of maintenance events.
- 5.15 Water champions should be assigned responsibility to cooperate with BMS managers in integrating water management into the BMS.

- 5.16 Further information on BMS installation and operation can be found in Health Technical Memorandum 2005 – ‘Building management systems’.

Metering and submetering

Metering

- 5.17 Information from water meters can be used by both water and sewerage service providers to carry out assessments for charging purposes and to aid water management within a facility.
- 5.18 Beyond the main service meter, additional submeters may be installed at floor, section or appliance level to provide data on internal rates of consumption. In all cases, it is important that the meter be appropriately sized according to average flow rate measured.
- 5.19 Main service meters that measure water entering from the supply network should be appropriately sized, as there is often a component of service charges which is based on meter size. Sizes may need to be reviewed after efficiency measures have been made inside the building, as flow rates may decrease.
- 5.20 Water meters should be properly installed, maintained and used according to the manufacturer's instructions. The meter supplier should calibrate the meter and check its accuracy.

Submetering

- 5.21 Submeters allow for management to measure consumption according to sections of the system. These can be especially useful for conducting water audits, by which areas of high use can be more precisely detected.
- 5.22 For monitoring purposes, submetering will also show area-specific rises in water consumption, indicating possible leakage.
- 5.23 The possibility of integrating submeters into building management systems should be considered.
- 5.24 For a case study of the use of meters in water management, see [Chapter 13](#).

Water quality, infection control, staff and patient welfare

- 5.25 While this document's principal focus is on water efficiency in healthcare facilities, many decisions

regarding water management will be affected by priority areas of water quality, infection control, and patient and staff welfare.

- 5.26 Where standards in water efficiency overlap with those in infection control and patient and staff welfare, existing guidance is referred to and should be consulted before management decisions are made (see Table 1). Further discussion of water quality issues can be found in [paragraphs 7.22–7.30](#).

Conducting an audit

- 5.27 A water audit is similar to a financial audit and can be as simple or as detailed as appropriate to meet circumstances and needs. In short, the audit looks at the amount of water entering the site, the amount leaving the site and the amount consumed. This basic calculation should provide an overview of costs, potential savings and areas of wastage. It will also highlight discrepancies, which will indicate leakage or other losses. The initial audit should

Table 1 Key health concerns and relevant documents

Key quality and health concerns	Relevant document
The control of water-borne infections, in particular legionellosis	- Health Technical Memorandum 04-01 – ‘The control of Legionella, hygiene, “safe” hot water, cold water and drinking water systems’ - Health Facilities Note 30 – ‘Infection control in the built environment’
The control of infection transmission pathways through appropriate choice of technology and through staff training on cleaning and personal washing	- Health Facilities Note 30 - Health Building Note 00-10 Part C - NHS Healthcare Cleaning Manual
The needs of vulnerable patients, such as vulnerability to scalding, ergonomic design and accessibility	- Health Technical Memorandum 04-01 - Health Building Note 00-02 – ‘Sanitary spaces’ - Health Technical Memorandum 00
Providing adequate points of access for drinking water and promoting the health benefits of hydration within the NHS estate and in the wider community.	Water UK has established the Water for Health Alliance, an industry initiative to promote the health benefits of hydration. The initiative includes guidelines for hospitals, available at www.wateratwork.org.uk/?page_id=13

Note

Planning teams should note the contents of ‘[The Health Act 2006: Code of practice for the prevention and control of healthcare associated infections](#)’ (Department of Health, January 2008). This code of practice sets out criteria by which managers of healthcare organisations are to ensure that patients are cared for in a clean environment and where the risk of healthcare-associated infections is kept as low as possible. The document contains a comprehensive list of the Department’s guidance on the prevention of healthcare-associated infection.

Case study: combining water efficiency and infection control and patient welfare

Dorset County Hospital, Dorchester, has embarked on a programme to change all of its WC flush valves and taps to non-touch types. This is partly due to the water efficiency achieved, but mainly because there is mounting evidence that non-touch products offer significant benefits to improving hand hygiene.

The same hospital had an outbreak of *Clostridium difficile*. There were no cases of the disease in areas

where non-touch taps were used. While it may be coincidental to some extent, it demonstrated the potential of hand hygiene and the benefits of non-touch taps.

Non-touch products not only offer water-saving and infection control benefits, but also convenience and ease of use for children and people with disabilities.

also aim to establish a framework for ongoing monitoring of water consumption inside the building or site (see Figure 5).

Figure 5 The water auditing process

- 5.28 In seeking support for conducting an audit, healthcare organisations should designate a key accounts manager to liaise with the local water company. Some water companies are able to offer water audits to high-consumption customers (see also [Chapter 11](#)).

Calculating water coming in

- 5.29 Existing data (such as bills, records and spatial plans of the site) should be collated, and also any other previous audits or reports on water. These should then be used to identify the main sources of water in the building or site, which may consist of private water supplies (for example boreholes), mains supply, bottled water, rainwater harvesting or water recycled within the building.
- 5.30 Plotting monthly water bills against time on a graph can help to analyse trends in water use and identify a departure from normal consumption levels. A gradual increase in monthly consumption may indicate a leak.

- 5.31 The possibility of downgrading to a smaller supply-pipe meter should be investigated, based on the data gathered, as this will reduce standing charges for water and sewerage services.

Note

In the analysis of water bills, account needs to be taken of any price increases, any appliances installed or removed, and significant changes in usage such as any ward closures etc.

Identifying areas of high use and leaks

- 5.32 Once the net use of water for a building has been estimated, areas of high use should be identified, as these provide the largest potential for savings. In some cases, a simple paper audit listing water-consuming fixtures and fittings within the facility, as well as their condition, will be a sufficient preliminary audit. Reference to [Chapter 6](#) should be made when considering which components to include in the audit.
- 5.33 In larger facilities, submeters provide a means of mapping water flows and analysing consumption according to different sections of the building. For more detailed audits, it may be worth installing submeters for audit and monitoring purposes. Gathering data on water use in different sections of the building may also identify leaks that are not immediately visible in monthly building-wide water consumption.
- 5.34 Identifying and repairing leaks is relevant to both efficiency and health in facilities. Metered charges will be reduced, as will the risk of contamination of the water supply. Engineering work that exposes pipework and/or produces a large amount of dust should be screened for infection risk (see [Health Facilities Note 30](#)).
- 5.35 Measuring flows during periods of low use (typically at night-time) can reveal unusually high base flows, which can indicate a leak in the area supplied. This may not be the case for buildings such as hospitals, in which daily patterns of water use are erratic and do not drop sufficiently at night-time. In such cases, metering may only be able to identify major long-term leaks (see [Figure 7](#)).
- 5.36 [Figure 6](#) is a hypothetical example, showing baseline consumption standing at 30 L per hour during night hours, possibly indicating a leak. [Figure 7](#) is an actual example of a hospital's

monthly consumption, illustrating a major leak that occurred in March 2000.

- 5.37 The healthcare facility's local water company should be able to assist in identifying leaks and anomalously high use. Almost all companies will offer free advice and some will offer free hands-on support.
- 5.38 They will also be able to advise on which types of meter to install and whether advanced metering technology would be useful.

In Scotland and Northern Ireland, Scottish Water and Northern Ireland Water, respectively, are the single providers of water. (With regard to commercial customers in Scotland, 1 April 2008 saw the introduction of competition in water services. Therefore, service providers are likely to vary.)

Welsh customers are mostly served by Dŵr Cymru (Welsh Water), with small portions served by Dee Valley Water and Severn Trent Water.

Calculating water coming out

- 5.39 As water services are charged according to separate water and sewerage charges, the amount of

wastewater discharged into sewerage pipes should be calculated. Often this is more difficult than calculating the water coming in, as it tends not to be metered. It is advisable to check the following:

- the location of sewer outflows;
- where rainwater drainage goes;
- whether there are any septic tanks or soakaways;
- whether any water is taken off site;
- steam losses.

Identifying objectives and developing an action plan

- 5.40 Having conducted a water audit, it should be possible to identify key objectives. These may be focused on identified leaks or may involve changing the management of water in those sections of the building with high water use.
- 5.41 In developing an action plan, both behavioural and technological options for management should be considered. As mentioned above, staff involvement in the design as well as the implementation of an action plan is essential. The initial results of the

Figure 6 Hypothetical daily consumption

Figure 7 Example of annual consumption for a hospital

water audit should be circulated to staff, and an opportunity to discuss the most appropriate actions provided.

- 5.42 Once a picture of water use and wastage emerges, the costs of each type of water should be calculated; this will indicate potential volumes and cost savings associated with water-efficiency options (outlined in [Chapter 6](#)).
- 5.43 The next action is to assess the capital costs of implementing changes to reduce wastage. Capital costs can then be compared against operational savings; this should provide a hierarchy of water-saving actions based on whole-lifecycle costs.
- 5.44 In making final decisions on water conservation actions, other factors should be taken into account, such as infection control, health and safety, staff acceptability, environmental costs and benefits, the implications for sewerage, and any energy savings or costs associated with the water-saving measures. When choosing the appropriate technology, it is important to consult with staff and the control of

infection team in order to identify any health risks or patients' needs that may be relevant.

- 5.45 A plan should consist of a clear, measurable set of key objectives that can be easily monitored and updated.

Note

The formulation of an action plan is considered best practice. It is not mandatory.

Implementation

Outreach

- 5.46 Once an audit is produced or a strategy is in place, it should be disseminated. A strategy should seek to empower and engage staff and patients, as half of all water savings can be generated through behaviour change, which can be free if the right atmosphere is created. Some suggestions for outreach are:

- an information pack or other communication that highlights the importance and value of efficient water use both in and out of the workplace;
- management rewards and ring-fencing of water savings;
- signs and notices on appropriate use next to water-using appliances; and
- informing local media (via a healthcare organisation's communications manager) of the new plan to raise the profile of water efficiency and local environmental policy.

Procurement and installation

- 5.47 Information on water-efficient devices is included in **Chapter 10**. When corresponding with contractors and consultants, water efficiency should be stressed as a priority.

Monitoring and maintaining standards

Benchmarking: hospital water consumption

- 5.48 Benchmarking helps to inform a manager about appropriate parameters for water efficiency.
- 5.49 As the size, design and use of healthcare facilities will vary considerably, a means of normalising water consumption across buildings is necessary. Normalisation may be achieved by calculating water consumed:
- per square metre of floor space (Table 2);

- per bed day (Table 3); or
- by person type (Table 4).

- 5.50 In each case, it may also be necessary to distinguish between building types in order to achieve a more realistic benchmark. It is recommended that benchmarking be used as a guideline for management rather than a stringent target.

Table 2 Hospital water use (expressed in cubic metres per square metre of floor area per year)

Type of hospital	Typical use	Best practice benchmarks
Small acute or long-stay hospitals without personal laundry	1.17	0.90
Small acute or long-stay hospitals with personal laundry	1.56	1.24
Large acute/teaching hospital	1.66	1.38

Source: Water UK (2003)

Recommended benchmarks

- 5.51 Table 2 reflects the findings of a Water UK study conducted in 2003, in which cubic metres of water per square metre of floor space per year was found to most accurately reflect data analysis. It was also found that the only activity within hospitals which significantly influenced consumption was laundry washing.

Table 3 Hospital water use (by patient bed days)

Type of hospital	Water per patient bed-day (m ³)			
	Very poor	Poor	Average	Good
Acute (>100 beds)	1.138	0.711–1.137	0.531–0.710	<0.530
Long-stay (>25,000 patient days per year)	0.690	0.412–0.689	0.331–0.411	<0.330
Long-stay (<25,000 patient days per year)	0.380	0.298–0.379	0.218–0.297	<0.217

Source: Audit Commission (1993)

Table 4 Hospital water use (expressed in litres per person per day)

Person type	Litres per person per day
Employee (full-time without canteen)	25–50
Employee (full-time with canteen)	40–90
Resident employee	180
Hospital patient (in-patient)	450

Source: Audit Commission (1993)

Other benchmarks

5.52 The benchmarks in Tables 3 and 4 are provided for information purposes only. However, if data necessary for calculating water consumption according to Table 2 (for instance total floor space) is not available, they may be used as guidance for water management.

Benchmarking: water consumption in healthcare facilities other than hospitals

5.53 The benchmarks given in Tables 2–4 may not be appropriate for other types of healthcare facility. Where the facilities are largely used for office work, it is advisable that building managers use the current government performance target of 4 m³ per employee per year (CIRIA, 2006).

5.54 In other instances, data for water consumption per square metre of floor space (collected through a recent Estates Return Information Collection (ERIC) survey) may help to indicate an appropriate consumption level.

Northern Ireland and Scotland have similar data-gathering systems.

5.55 Table 5 and Figure 8 provide figures for a number of healthcare facilities. Data is given according to upper and lower quartiles and median values. These values should be taken as indicators only.

Table 5 Annual water consumption (litres per occupied floor area)

Building type	Consumption (m ³ per m ² per year)		
	Q1	Median	Q2
Ambulance	0.969	0.716	0.535
PCT	1.092	0.798	0.567
Children's services	1.116	1.088	1.053
Mental health	1.39	1.222	0.973
Care trust	1.636	1.227	0.776
Community	1.412	1.248	1.135
Acute specialist	1.844	1.29	1.128
Orthopaedic	2.018	1.458	0.902
Acute teaching – outside London	1.771	1.596	1.39
Learning disabilities	2.072	1.682	1.422
Acute – outside London	1.906	1.7	1.499
Multi-service	2.219	1.702	1.492

6 Suggested components of a water strategy

Boilerhouses

- 6.1 Optimising boiler performance and maintaining the system can save large amounts of water. This can be very cost-effective and will have a significant impact on reducing a facility's carbon footprint, since hot water and steam have a great deal of embedded energy.
- 6.2 When making any changes to boiler management or alterations to design, suitably trained personnel or companies must be employed.
- 6.3 In addition to manufacturers' instructions, the Health and Safety Executive's (HSE) Guidance Note PM5 – 'Automatically controlled steam and hot water boilers' should be consulted prior to any action.

Boiler feed-water pre-treatment

- 6.4 Feed-water entering the boiler will frequently need to be demineralised in order to reduce solid deposits in the system. This process often involves the use of ion-exchange beds. These beds require frequent regeneration, typically through the use of hydrochloric acid or caustic soda. Water is used to flush the regeneration agents from the beds and is then considered effluent.
- 6.5 Water may be conserved by conducting the regeneration process only when needed, rather than at regular daily intervals. Trigger levels for regeneration can be defined either by volume of water treated or by monitored conductivity breakthrough of the bed.

Boiler blowdown

- 6.6 Throughout operation, boiler units gradually build up concentrations of total dissolved solids (TDS). At sufficient concentrations, these TDS precipitate from the water and form solid material in the boiler unit, impairing efficiency and heat transfer. In order to avoid the water reaching high concentration of TDS, water should occasionally be dumped from the boiler; this is called "blowdown".

- 6.7 Older models of boiler may continuously remove water from the top of the water tank or they may flush the system out at predetermined intervals. A blowdown system that is activated only when TDS concentration exceeds a certain threshold may provide significant energy and water savings. Calculations and decisions should be made by a competent person.

Steam losses, leaks and condensate recovery

- 6.8 As steam travels through the outlet pipes of a boiler, its temperature decreases and water condenses in the pipes. This condensate can be collected and recycled into the boiler system, reducing energy and water consumption as well as slowing the build-up of TDS (as the condensed water tends to have a much lower TDS content).
- 6.9 The energy required to produce steam is extremely high. Approximately 80% of the energy used in a boiler is used in providing the necessary latent heat to produce steam, with only 20% attributed to raising water to boiling point; care should be taken to prevent steam losses from the system and to ensure that the necessary safety precautions are in place.
- 6.10 Installing heat exchangers (sealed thermal units) should be considered, as this will reclaim otherwise lost heat and will help to curb the risk of *Legionella* growth.

Cooling towers

- 6.11 Cooling towers are used to transport heat from processes within the building to the roof. The process involves pumping water to holding tanks on the roof where water is allowed to evaporate – cooling the remaining water. In a similar manner to boilers, as water is lost through evaporation, the concentration of TDS grows. In order to prevent the build-up of solid materials in the tower, water must occasionally be bled from the system and make-up water introduced.

- 6.12 Alternatives to using cooling towers for temperature control are outlined in the Building Research Energy Conservation Support Unit's (BRESCU) General Information Report 85 (GIR085) – 'New ways of cooling: information for building designers'. (See also the Health and Safety Executive's (2000) 'Approved Code of Practice: Legionnaires' disease – the control of legionella bacteria in water systems'.)

Cycles of concentration

- 6.13 The rate at which water is replaced in cooling towers is determined by the "cycles of concentration" (CoC) value. This value describes the acceptable ratio between the TDS bled from the cooling tower system and those introduced. Systems at lower CoC will use more water to maintain the required TDS value. Calculations and decisions should be made by a competent person.

Additional losses

- 6.14 Losses due to factors other than evaporation and bleed water can be calculated using the following equation:

$$\left(\frac{\text{Make-up water}}{\text{Cycles of concentration (CoC)}} \right) \times \text{Bleed water}$$

Catering department

- 6.15 The catering department constitutes a significant portion of total water consumption in healthcare facilities, and may benefit from being submetered for monitoring purposes. Reducing water waste in this department requires a combination of behavioural change in staff and appropriate changes to technology. Suggestions for informing staff on how to conserve water are outlined below, followed by technical advice.

Washing and preparing food

- 6.16 Staff awareness concerning efficient use of water in food preparation should be raised on the following points:
- **Taps:** A running tap can typically consume 12 L/min. An effort not to leave unused taps running should be made – signs next to taps may be effective. Technology such as flow restrictors and automatic shut-off mechanisms will also reduce waste.
 - **Defrosting:** Defrosting food under running hot water should be avoided when possible.

Changing management of frozen foods to avoid using hot water for defrosting will save water and may be more energy-efficient.

Waste disposal

- **Recycling:** When preparing packaging for recycling, the recycling authority should be consulted on whether it is necessary to wash/rinse packaging.
- **Automatic potato peelers:** Peelers often require a water supply to flush out potato peelings. Flows should be set at the minimum amount required. A flow-restricting valve can be used to achieve this.
- **Food waste disposal channels:** Larger kitchens occasionally use channels of water running through the facility to transport organic waste to a macerator, which is then released into the sewers. If an alternative method of collecting food waste cannot be implemented, channels should be managed with the following in mind:
 - channels should only flow when the kitchen is in use and there is a need for them;
 - the number of channels should be kept to a minimum;
 - flow rates in the channel should be regulated and kept to a minimum.
- **Reducing waste:** Where the amount of waste entering the sewerage system is significant, water companies may charge an additional "trade effluent" charge. Reducing the amount of waste entering the sewerage system will help to reduce or remove such charges where present.

Washing

- **Dishwashing and laundry:** Daily uses should be evaluated for dishwashers and washing machines, and a washing routine which ensures that machines are completely full before turning them on should be established. When replacing machines, water-efficient models should be selected. In larger facilities, industrial-standard machines will be required, and procurement should be based on the most efficient model, taking into account whole-life costings.

In the case of smaller estates where domestic (as opposed to industrial) washers are used, a database of domestic dishwashers and their efficiency ratings is available from the Waterwise website.

- **Washing food-preparation areas:** In larger kitchens, surfaces and equipment are often washed down using a hose. If hoses are used, there is a need to reduce the risk of aerosol formation.

Sanitary appliances

- 6.17 Non-process uses of water are commonly referred to as “domestic”. Domestic appliances consist of WCs, urinals, taps, baths and showers. It is likely that domestic uses will be the most cost-effective area for water efficiency as they constitute a large portion of water consumption in hospitals and other healthcare facilities. This section outlines options for upgrading technology and changing staff behaviour and the resulting water savings.
- 6.18 The use of water-efficient fittings and appliances may not be appropriate to the needs of the patient and may adversely affect the incidence and propagation of infections (see Health Technical Memorandum 00 and Health Building Note 00-02 for further guidance). Managers are also advised to refer to the control of infection team before any measures are taken (see also Health Technical Memorandum 04-01).

WCs

- 6.19 Water consumption per flush for WCs will depend on the age of the model, as will options for upgrading or retrofitting. Often WCs are the first choice for water efficiency, as they constitute a large portion of domestic use. Older models may use as much as 12 L per flush, whereas newer models consume around 4–6 L. The Water Supply (Water Fittings) Regulations 1999 (Water Byelaws in Scotland; Water Regulations in Northern Ireland) require any new WC installations to use a maximum of 6 L per flush (7.5 L in Northern Ireland) (see Health Technical Memorandum 00 and Health Building Note 00-02 for further guidance).

Cistern displacement devices (CDDs)

- 6.20 A cistern displacement device (CDD) may be used to displace a set volume of water inside the WC

cistern, saving water on each flush. CDDs typically save around 1 L of water per flush.

- 6.21 Care should be taken to install a CDD appropriate for the WC model and that still provides an adequate flush volume. CDDs offer a simple low-cost method of reducing WC flush volumes; however, consideration should be given as to whether it is better to use CDDs or to upgrade WCs to low-flush models, which may also be easier to maintain and ergonomically better to use.
- 6.22 Generally, CDDs may be useful for clinics and WCs in GP surgeries, but large-scale use of CDDs in a hospital may indicate the need to refurbish the WCs.

Retrofitting flush mechanisms

- 6.23 As mentioned in paragraph 6.19, WCs manufactured after 2001 are subject to regulations enforcing a maximum flush of 6 L. Older WCs that consume as much as 12 L per flush can be retrofitted with flushing mechanisms that allow the user to vary the flush volume. Depending on the age of the WC, water savings of up to 5 L per flush are possible. Users control the flush either through a choice between a full and a half-flush (dual flush) or through releasing the flush handle to cut the flow of water (variable flush). If such a device is installed, clear instructions on its use should be displayed near the WC.

Installing new water-efficient WCs

- 6.24 When installing a new WC, it should be confirmed that the model has been approved by WRAS. WRAS-approved WCs consume as little as 4 L per flush and 2.6 L per reduced flush. When upgrading WCs, a dual-flush water-efficient model should be considered (see Health Technical Memorandum 00). Drainage facilities for new sanitary equipment should be designed to cope with the maximum expected production of waste.

Urinals

- 6.25 Urinals are often controlled through an automatic flush system which is triggered at regular intervals. A typical system will flush volumes of approximately 7.5–12 L of water at 20-minute intervals. This can amount to as much as 197 m³ per year per urinal, resulting in unnecessary water and sewerage charges. Installing passive infrared detectors in urinals typically reduces water consumption by 60%. Costs stand at £120–£150,

but payback is rapid. Further options include installing more water-efficient models when upgrading, or considering waterless urinals for certain areas; however, the infection control team should be consulted before installing waterless urinals (see Health Technical Memorandum 00 and Health Building Note 00-02 for further guidance).

Note

With regard to waterless urinals, there may be issues over perception and maintenance, as cleaning staff may not be familiar with these types of urinal. It is recommended that the use of waterless urinals is discussed with medical and cleaning staff before a decision on installation is made. There are also ultra-low-flush urinals available that may overcome any perceived hygiene issues.

Some waterless urinals use disposable cartridges or other devices, which need changing routinely. The system also needs to be flushed occasionally to remove any debris. Both of these tasks will need to be accounted for in an agreed maintenance contract, which must then be evaluated in terms of additional costs introduced versus the water savings, as well as the appropriate levels of maintenance necessary to ensure good hygiene.

Taps

Leakage

6.26 Taps are prone to leakage. It is estimated that a dripping tap may consume around 15 L per day. Staff should be informed of the importance of reporting leakage and a reporting system should be put in place.

Design

- The uses of taps should be considered before reducing flow rates. In some cases, reducing flow rates may be inappropriate. For instance, where taps are used to fill containers, reducing flow rates will only increase the time taken and will have little effect on efficiency. In other cases, where the risk of spread of infection is particularly high (for example surgical scrubbing), sensor-, lever- or foot-operated taps may be most appropriate.
- Taps typically use about 9 L of water per minute, but may use as much as 18 L per

minute. Staff should be informed of the importance of using taps appropriately.

- Sensor (non-touch) taps may in some cases be ideal, as they both conserve water and reduce the risk of infections spreading.
- The fitting of non-concussive self-closing taps can also reduce unnecessary flow.
- Flow regulators may also be fitted to taps, as appropriate.

See Health Technical Memorandum 00 for guidance on the appropriate types of tap for use in healthcare facilities.

Baths and showers

6.27 Baths typically use around 80 L per event and showers around 9 L per minute. Where possible, showers should be favoured over baths; however, the care needs of patients must take priority. Reducing the water used for showers and baths may also potentially reduce energy bills due to a reduction in hot water used.

Shower technology

- Flow restrictors may be used to reduce the flow rate of water in showers.
- Shower location and design can significantly reduce the amount of water wasted due to waiting for showers to reach the desired temperature. In addition, in healthcare facilities there is a risk of scalding for vulnerable patients, the very young, older people and patients with mental-health illnesses. Upgrading to thermostatic mixing valves will minimise this risk (see Health Technical Memorandum 04-01 and Health Technical Memorandum 00).
- Fitting water-efficient showerheads may reduce water consumption significantly.
- There should be efficient ventilation to control aerosol dispersion.

Medical activities

Surgical scrubbing

6.28 The NHS carries out about 7 million operations a day; each one will require a minimum of two staff to scrub. Scrub taps are generally lever- or sensor-operated. This is an essential area of water use;

reduced flow taps should not be used (see also Health Technical Memorandum 00).

Dialysis unit

- 6.29 In a renal unit, water quality should meet the recommendations specified by the European Renal Association-European Dialysis and Transplant Association's (ERA-EDTA) 'European best practice guidelines for haemodialysis'. To ensure purity, water is passed through a reverse osmosis (RO) unit. This means that water can be reused (for WC flushing, for instance) as the RO unit can remove almost any level of contamination (see also "Example 4" after paragraph 4.7).

Patient care

- 6.30 Patient bathing, WC use, washing and drinking can use a large amount of water. However, the best way to reduce waste is by ensuring all the appliances used by patients are efficient. Indeed, patients should be encouraged to use more water through good hydration and personal washing. All hospitals should provide easy access to drinking water for patients, and the promotion of good hydration should be stated in any water management plan.

Laser cooling

- 6.31 Medical lasers are generally water-cooled. Owing to the cost and sensitivity of the equipment, water efficiency should be a secondary consideration after ensuring water purity (to prevent corrosion) and cooling efficiency. Depending on the type of laser, it may be possible to use thermoelectric cooling or air cooling, but water efficiency should not be a driving factor in choosing cooling systems.

Hydrotherapy pools and swimming pools

- 6.32 Hydrotherapy is a therapeutic whole-body treatment that involves moving and exercising in water – physiotherapy in a pool. Hydrotherapy pools are usually different from ordinary pools – the temperature and movement of water is controlled and changed according to who is using the pool and why. Pool covers can reduce evaporation losses. Filtration units can be used to recirculate water. This is common on modern pools, but is expensive to retrofit; however, the Health Protection Agency's (1999) 'Hygiene for hydrotherapy pools' states that most pools should have a filter.

Birthing pools

- 6.33 Birthing pools can use around 500 L of water per use. For hygiene reasons, the water cannot be reused without extensive treatment. The only way to increase water efficiency is through the shape of the pools; however, medical and comfort considerations should take priority over water efficiency. If considering installing birthing pools, there are three points to take into account:
1. They will use a great deal of water.
 2. They are very heavy – therefore, the structural integrity of the building should be considered if a number of pools are situated in the same area of a floor.
 3. They require a great deal of cleaning, which will use much water.
- 6.34 Some hospitals may also have mobile birthing pools.

Decontamination

Endoscopy

- 6.35 This is an area where water efficiency is unlikely to be acceptable from a clinical perspective and where water reuse may pose an infection threat. For further guidance on decontamination in endoscopy, see Health Technical Memorandum 01-06 – 'Decontamination of flexible endoscopes'.

Sterile services departments

- 6.36 It is very difficult to improve water efficiency in essential support services such as sterile services. While trying to promote water-efficiency measures, it is important to remember that the decontamination process should not be compromised in any way.
- 6.37 However, it is recommended that:
- all decontamination equipment (washer-disinfectors and sterilizers) operates with full loads;
 - wash cycles are evaluated for water-use efficiency.

Outdoor use

- 6.38 Few healthcare facilities have considered the amount or type of water used for outside watering, or the selection of plants. Given that a single water sprinkler may consume as much as 900 L of water

an hour, the costs of outdoor use are potentially large. Consider the following solutions to reducing outdoor use:

- **Rainwater harvesting:** this may be ideal for plant watering, as the collected water requires little or no treatment (see [paragraphs 7.9–7.11](#)).
- **Plant choice:** consideration should be given to installing drought-resistant or perennial plants in estate grounds; these will need little water and will add diversity.
- **Sprinkler timings:** sprinkler timings should be adjusted such that they are active in the early morning or late afternoon; this will reduce water loss due to evaporation.
- **Mulching:** mulch and bark should be used in flower and tree beds; this will reduce the loss of water through evaporation by up to 70%.

7 Whole building concerns

- 7.1 Achieving good water management in healthcare facilities will demand that decisions about issues such as security of supply, water quality and flood risk are assessed in terms of impacts on the entire building (see also Health Technical Memorandum 00 and Health Technical Memorandum 04-01 for further guidance).

Alternative supply sources

Boreholes/private supplies

- 7.2 The use of water abstracted from private sources may be feasible in some circumstances.
- 7.3 Where water quality is not required to be at a potable standard (for instance in cooling equipment or flushing urinals and WCs), it may be possible to use water directly abstracted from a borehole.
- 7.4 Where water is to be used for human consumption or cleaning, filtration and/or further treatment may be necessary to comply with the Private Supplies Regulations 1991 and Water Industry Act 1999.

In Northern Ireland, this is covered by the Water and Sewerage Services Order 2006, and in Scotland by the Water Supply (Water Quality) Regulations 2001.

- 7.5 Boreholes are drilled through underground strata that contain water (known as aquifers). Water is then abstracted through a submersible pump at depths varying from 20 to 200 m. The water is then stored in a holding tank on the surface.
- 7.6 In each case, feasibility of abstraction will depend on the availability and quality of groundwater, which can be established through a preliminary survey. Once this has been verified, abstraction will require a licence.

In England and Wales, licences are managed by the Environment Agency and often depend on the density of abstractors in the area, managed through local CAMS. In the case of Scotland, abstraction licences are provided by the Scottish Environment Protection Agency, and in Northern Ireland by the Department of Environment.

- 7.7 There are potentially large financial savings to be made through private abstraction; however, the long-term costs of water supply from water companies must be balanced against the following:
- the capital costs of the construction of works, mains, plumbing, treatment plant etc;
 - the operational costs of electricity for pumping, water treatment chemicals, direct and indirect maintenance, and associated management costs.
- 7.8 Once all factors are taken into account, a decision to develop a private water supply can be made. **Figure 9** is an example of a decision tree outlining the key factors.

Rainwater harvesting

- 7.9 Harvesting rainwater that falls on property roofs may be economically feasible for larger buildings. Water collected from roofs may be used for low-quality purposes such as laundries and WC/urinal flushing. The payback period will vary depending on the size of the roof and annual rainfall values.
- 7.10 Systems supplied should have an alternative automatic supply (for instance where rainfall is insufficient).
- 7.11 Depending on where the water is harvested from, there may be issues with water quality (bird droppings and pesticide deposits are commonly present on roofs). It should always be presumed that rainwater is non-potable, and it should not be used where ingestion is a possibility.

Figure 9 Decision tree for establishing a private water supply

At the time of writing this guidance, industry standards for rainwater and greywater harvesting have not yet been developed, but a British Standard is in preparation.

Visit the UK Rainwater Harvesting Association's website for further information.

Greywater reuse

7.12 Greywater and rainwater are often discussed together. Greywater is water that has been previously used and is almost certainly contaminated.

7.13 Greywater should not be used in healthcare premises. However, there may be circumstances where its use may be acceptable on a case-by-case basis. Where greywater is to be considered, a risk assessment should be undertaken that considers all the potential microbiological risks that may result from such a change of use. This assessment should involve a microbiologist and infection-control staff.

7.14 Technology for greywater reuse is advancing very quickly and there may be certain circumstances where the type of greywater or the certainty of the

technology can allow greywater reuse. Each case should be judged on its merits, balancing risks and benefits, and should be discussed fully with staff before implementation. Any implementation should also ensure that all pipes and equipment carrying or using greywater are clearly labelled.

Water security

7.15 To guard against an interruption in supply, Health Technical Memorandum 04-01 stipulates that at least 12 hours' supply of cold water should be stored on site. Guidelines also state that a maximum of 24 hours' supply of water should be stored in order to avoid stagnation of water in supply tanks and the resulting risk of *Legionella* growth and transmission.

7.16 Where actions are taken to reduce water consumption in existing buildings, the amount of water required to supply the building for 12 hours will reduce, as will the turnover rate of water in the storage tank. Where it is calculated that a building has significantly reduced the amount of water used per day, the possibility of reducing storage tank sizes should be investigated.

7.17 The required storage volume should be calculated for a 12-hour demand scenario, including peak periods of demand. Similar calculations should be made if there is a reduction in turnover times for wall-mounted calorifiers, with a maximum of two hours' storage time available, including peak demand.

7.18 In addition, the turnover rate of water in all pipes within the building should be considered. The risk of water remaining stagnant in the distribution pipes will rise – particularly in deadlegs.

7.19 Where fixtures are rarely used, the possibility of removing the fixture and any deadlegs supplying it should be considered.

7.20 A water management strategy should consider the logistics of ensuring water supply. The following questions should be addressed:

- In the case of a "boil water" notice from the local water company, how will water be boiled and distributed around the site?
- In the case of interruption to the supply, where are the connection points for water supplied by a tanker?

7.21 It may be necessary to have arrangements for bringing in drinking water to ensure patients

do not dehydrate (see also Health Building Note 00-07 – ‘Resilience planning for the healthcare estate’).

Water quality

- 7.22 In all circumstances, water efficiency should not compromise water quality and safety requirements. Issues relating to these requirements are discussed below.

***Legionella* and internal hot and cold distribution networks**

- 7.23 Related to the issue of security of supply is the overall risk of *Legionella* growth. High-risk scenarios of *Legionella* growth include those where water remains stagnant in tanks and distribution pipes for extended periods of time, particularly under favourable temperatures. For cold water supplies, water temperature should not exceed 20°C and should aim to be no more than 2°C warmer than the temperature recorded at the main supply pipe. For hot water supplies, flow temperatures should be set to 60°C, and a minimum of 55°C should be maintained at all points in the network (see Health Technical Memorandum 04-01 for further guidance).

Water hardness

- 7.24 Water hardness is expressed in terms of milligrams per litre of calcium carbonate (CaCO₃). The hardness of water supplies will depend largely on the region in which the water is abstracted.

For a map of hardness, see the report ‘Water hardness in the British Isles’ on the Waterwise website.

- 7.25 Higher hardness levels may adversely affect equipment – as water is heated, its capacity to carry dissolved salts decreases, leading to calcium deposits on pipe walls and heating elements, thus decreasing efficiency. It may therefore be appropriate in some cases to install water softeners for certain uses. Possible uses that may benefit from softening are:
- boilers and hot-water supply systems – to prevent sludge and limescale build-up;
 - mixing devices and blending valves – to avoid clogging of control ports and showerheads by limescale;
 - laundries – water hardness leads to high maintenance costs and the uneconomic use of soap detergents.

- 7.26 In the case of drinking water, epidemiological studies have shown that the incidence of cardiovascular disease tends to be higher in areas of soft-water supplies than in areas with hard water. The association is clearest in supplies which contain less than 150 mg/L. The explanation is not known, but it is advised that where water is used for drinking supplies, it should not be softened.

Metal contamination

Water softness and monitoring

- 7.27 Where water is acidic and particularly soft, its capacity to dissolve metals is higher. In such cases, regular sampling through the building should be conducted to identify possible contamination from the original source or the internal distribution network.

Lead

- 7.28 The Water Supply (Water Quality) Regulations 2000 stipulate an upper limit of 0.01 mg/L to be achieved in all supply by 2013; this value is likely to be exceeded if lead pipework or solder containing lead has been used in building plumbing systems. Should a value higher than 0.01 mg/L be detected, remedial action should be taken.

Copper

- 7.29 Copper concentrations above 1 mg/L may cause staining of laundry and sanitaryware and increase the corrosion of galvanised iron and steel fittings. While the maximum allowable copper concentration in water supply is 2 mg/L, a typical supply will be below 1 mg/L.

Specialist units

- 7.30 In general, the supply of water to certain specialist units such as maternity departments, neo-natal units, children’s units and renal dialysis areas should be monitored to ensure that water quality is within acceptable limits. Epidemiological advice should be sought concerning the exact water quality requirements for each specialist unit.

Wastewater and sewage

Sewage

- 7.31 Sewage accounts for over 50% of water and sewage costs to the NHS. Unlike water, which is metered, sewage bills are normally based on water use.
- 7.32 Standing charges for sewage depend on the size of the incoming water meters and the volume of water consumed.
- 7.33 It is possible to negotiate an allowance with water or sewerage companies for water that is not returned to the sewer. For clinics and GP surgeries, where water use is domestic, sewage rates are based on 95% return, but hospitals have higher evaporation losses, and returns to sewer could be as low as 70%.
- 7.34 Once an audit has been carried out or the water balance has been assessed, a rebate with the water or sewerage company should be negotiated. In some areas, water and sewerage are provided by a single company; in others, there may be two separate companies.
- 7.35 Water and sewerage companies classify effluent discharges as either domestic or trade. Most healthcare facilities' wastewater is classified as domestic. However, parts of certain sites, such as laundries or laboratories, could possibly be classified as trade. The classification varies between water companies.
- 7.36 Charges for trade effluent depend on the toxicity of the wastewater. If a healthcare facility has a trade tariff, it should contact its local water or sewerage provider about how to reduce toxicity and thus reduce charges.
- 7.37 The volume flow of effluent is the most important factor in determining the bill. However, it is very common for trade effluent flows not to be measured. In such circumstances, the volume of effluent is assumed to be the same as the volume of water purchased, as recorded on the site's incoming water meter. This figure may be used as it stands or after some modification for losses as steam or in product use.
- 7.38 In general, what is going into the drains at the facility should be assessed. Increasing water efficiency will reduce sewage bills as well as water bills, and it will also highlight areas where wastewater can be reused. As the level of wastewater

reuse increases, consideration should be given to opportunities to renegotiate the sewage return rate.

- 7.39 It is therefore very important to take all steps to reduce water consumption and, where practical, to measure or make a reliable estimate of the flow of effluent that enters the sewer. The flow of water and effluent through the premises should be mapped and analysed; all opportunities for reducing water use should be noted. It should be determined whether any cooling water or rainwater that flows to sewer would be sufficiently clean for direct discharge to a ditch; this may require discharge consent from the Environment Agency (England and Wales).

In Northern Ireland, discharge consent is given by the Department of Environment, and in Scotland by the Scottish Environment Protection Agency.

- 7.40 It is also worth monitoring the contents of wastewater; this will enable a reduction of the contaminants in sewage and will enable optimised chemical use in certain processes. A reduction in contaminants may also reduce trade effluent charges.

Sustainable urban drainage systems (SUDS)

- 7.41 Discharge of clean wastewater or drainage water to a soakaway, swale or infiltration area is often classified as a sustainable urban drainage system (SUDS). This method can reduce sewage or drainage bills, but may require discharge consent from the Environment Agency.

In Northern Ireland, discharge consent is given by the Department of Environment, and in Scotland by the Scottish Environment Protection Agency.

- 7.42 When designing new buildings, re-landscaping or adding car parking, a SUDS should always be considered. Well-designed drainage systems can reduce landscape watering requirements, add biodiversity through the creation of wetland areas, reduce drainage charges, and – if the water is captured in rainwater tanks – provide water for irrigation, WC flushing and fire-fighting. However, water quality should be assessed before using rainwater or greywater inside any healthcare facility (see also [paragraphs 7.9–7.14](#)).

Hospital sources of sewage pollution

7.43 Freshwater quality in healthcare facilities is paramount; however, the contamination of wastewater should not be overlooked. Reducing contaminants released into the sewerage system will significantly contribute to improving the natural environment, into which the contaminants could otherwise be released (see Table 6).

- It can cause or exacerbate leakage.
- It causes a higher flow-rate of water through appliances.

Calculating changes in flow rate due to water pressure

7.46 In general, the following approximation for change in flow rates due to a change in pressure can be used to determine the effects on taps, showers, hoses etc.

$$\text{New flow rate} = \text{Old flow rate} \times \sqrt{\left(\frac{\text{New pressure}}{\text{Old pressure}}\right)}$$

Equation (1)

Discharges to sewers: red list chemicals

7.44 The chemicals shown in Table 7 must not be discharged to sewer.

Water pressure

Effects of high pressure

7.45 Excessive water pressure can contribute to waste in the following ways:

- It places additional and unnecessary wear and tear on the distribution system.

See also Figure 10, which shows an example calculation for a tap with a base flow of 8 L per minute at 1 bar pressure.

Table 6 Possible contaminants to the sewerage system from hospital sources

Source	Main contaminants	Officer responsible
X-ray	Photographic fixer	Superintendent/senior radiographer
Nuclear medicine	Aqueous radioactive isotopes	Medical physicist
Pathology laboratories	• Aqueous radioactive isotopes • Solvents • Heavy-metal compounds • Tissues: human/animal	Laboratory manager
Dental departments	Mercury	Chief dental technician
Dispensing pharmacy	Drugs	Chief pharmacist
Manufacturing pharmacy	Batch failures of products	Chief pharmacist
Medical illustration	• Photographic fixer • Photographic developer	Chief technician
Laundry	• Detergents • Contaminants on laundry	Laundry manager
Sterile services department, endoscopy unit	• Detergents • Disinfectants • Microbial contaminants	Unit manager
Catering	• Cleaning agents • Macerated food	Catering manager
Incinerators	Ash	Estates manager
Domestic maintenance	Cleaning agents	Domestic services manager
Vehicle maintenance	Spent oil	Transport manager
Grounds maintenance	• Pesticides • Nitrate fertilisers	Grounds manager
Blood transfusion centre	• Aqueous radioactive isotopes • Crushed glass	Unit manager

Table 7 Red list chemicals

All flammable and water-immiscible substances
1,2-Dichloroethane
Aldrin
Atrazine
Azinphos-methyl
Cadmium and its compounds
Dichlorodiphenyltrichloroethane (DDT)
Dichlorvos
Dieldrin
Endosulfan
Endrin
Fenitrothion
Gamma-hexachlorocyclohexane
Hexachlorobenzene
Hexachlorobutadiene
Malathion
Mercury and its compounds
Pentachlorophenol and its compounds
Polychlorinated biphenyls
Simazine
Tributyltin compounds
Trichlorobenzene
Trifluralin
Triphenyltin compounds

Sources of high pressure

- 7.47 Water is supplied according to minimum flow and pressure regulations, typically at around 2–4 bar; however, maximum pressure would not typically exceed 10 bar. High pressure supplies may occur where buildings are located down-gradient from storage reservoirs (for example when a reservoir is located on top of a hill and the building is in a neighbouring valley).
- 7.48 High pressures may also occur due to building design. Lower floors of multi-storey buildings in which water is supplied under gravity from a break tank in the roof may experience high pressures. High pressure may also occur when water is delivered via booster pumps inside the building.

Managing water pressure

- 7.49 Pressure-reducing valves (PRVs) can act as pre-set or adjustable pressure controls. Typically a valve can accept up to 25 bar pressure, and control this to a delivered 1.5–6 bar.
- 7.50 Valves can be installed in incoming mains pipes and are also commonly used to regulate supply pressure on each floor of a building in gravity-fed or pumped systems.
- 7.51 When selecting the size and setting of PRV, input and output pressures should be taken into consideration. The valve should be suited to the

Figure 10 An example calculation for a tap with base flow of 8 L per minute at 1 bar pressure (with further flow rates calculated using Equation (1))

level of incoming pressure and should ensure an adequate flow rate for all appliances it supplies. This is particularly the case for mixer taps and showers (see Health Technical Memorandum 04-01).

Water temperature

7.52 Owing to the risk of *Legionella* growth, hot and cold water supply temperatures should be closely monitored and maintained (see [paragraph 7.23](#)). Insulating distribution pipes will help to maintain

stable temperatures and will reduce waste by decreasing the waiting time for water to reach the desired temperature in taps and showers.

7.53 When designing new buildings, efforts should be made to reduce the length of hot-water supply pipes to fixtures, as this will reduce the time allowed for heat to dissipate through pipes. Point-of-source heating may be appropriate where there is a particularly large lag-time in water temperatures (see Health Technical Memorandum 04-01).

8 Flood risk

- 8.1 The water strategy should contain contingencies for flooding. Flooding can be coastal flooding, river flooding, localised flooding due to high rainfall, or groundwater flooding where water seeps up from below.
- 8.2 In addition to the immediate threat of flood waters, flooding may disrupt water supplies through contamination of the mains supply or damage to pumping stations. Contamination of water within the building's own system is also a risk.
- 8.3 Guidelines on developing new build and extending existing building in the context of flood risk are provided in the Department for Communities and Local Government's Planning Policy Statement 25 – 'Development and flood risk'.

In Northern Ireland, guidance is provided in Planning Policy Statement 15 – 'Planning and flood risk'.

Mitigating flood risk

- 8.4 When designing new buildings or extensions to existing buildings, the following should be taken into account.
 - **Consult the flood risk maps:** flood risk maps are available from the Environment Agency (England and Wales), Department of Environment (Northern Ireland), or the Scottish Environment Protection Agency, and will provide initial guidance on appropriate construction sites for new build. These maps can be found at:
 - www.environment-agency.gov.uk/homeandleisure/37837.aspx (England and Wales).
 - **Design to reduce risk:** both new buildings and refurbishments will alter surface shape and permeability, affecting the dynamics of flood risk in terms of timing, volume and areas of accumulation. Designs should adhere to the principles of SUDS, in which the principal aim

is to mimic as closely as possible the natural drainage dynamics of an area in order to reduce the risk of flooding to buildings nearby. Approaches include improving drainage through semi-permeable surfaces in areas such as car parks and channelling flood paths away from high-risk areas into "sacrificial land", in which water is allowed to collect and drain away.

- **Direct flood defence:** bunding walls can be installed to redirect flood waters. This is a more traditional approach; however, efforts to reduce risk should be made before conventional flood defences are installed.

- 8.5 However, in mitigating flood risk to one site, it should not be passed on to create flood risk at another vulnerable site (see Health Technical Memorandum 07-07 – 'Sustainable health and social care buildings').

Responding to flooding

- 8.6 Contingency plans for flooding should be drawn up and should include the following:
 - options for securing alternative supplies for essential water uses;
 - screening back-up-generator power supplies for resilience to flooding;
 - a full citing of patients, equipment, power lines and communications cables that are at risk from flooding;
 - options for evacuation of patients and staff, including routes, assembly points and responsibilities;
 - accessibility for services to get to the site.

See also the Department of Health's "preparedness for floods" website.

9 Responsible bodies in water management

Consumer councils

Consumer Council for Water (CCWater)

The Consumer Council for Water (CCWater) is the industry watchdog, set up to represent customers of water and sewerage companies in England and Wales, and provides a national voice for consumers.

www.ccwater.org.uk/

Department for Environment, Food and Rural Affairs (Defra)

The Department for Environment, Food and Rural Affairs (Defra) is a governmental organisation responsible for water supply and resources, regulatory systems for the water industry and environmental protection.

www.defra.gov.uk/

Drinking water regulators

Drinking Water Inspectorate (DWI)

The Drinking Water Inspectorate (DWI) is responsible for ensuring that water companies and suppliers in England and Wales meet their statutory duties in relation to drinking water quality. The Inspectorate does this through a programme of technical audit to ensure that water companies are taking appropriate actions to safeguard drinking water quality. The Inspectorate can call on powers of enforcement and (where appropriate) prosecution to legally enforce the requirements of the legislation.

www.dwi.gov.uk/

Economic regulators

Water Services Regulation Authority (Ofwat)

The Water Services Regulation Authority (Ofwat) is the government-appointed economic regulator of the private water industry in England and Wales. Its remit is to protect the interests of water-company customers while ensuring water companies are able to properly finance and carry out their functions. It determines prices through periodic reviews of water-company expenditures and future plans.

www.ofwat.gov.uk/

UK environmental regulatory authorities

Environment Agency

The Environment Agency is responsible for the protection and preservation of the natural environment in England and Wales. Its role in the water industry is to ensure that water-company operations do not adversely affect the water environment and are sustainable in the long term. As well as reviewing water-company plans, it regulates abstraction licences and is responsible for flood risk management.

www.environment-agency.gov.uk/default.aspx

Water UK

Water UK represents the private water industry in the UK. It actively seeks to develop policy and improve understanding in areas that involve the industry, its customers and stakeholders.

www.water.org.uk/

10 How to find water-efficient products

Bathroom Manufacturers Association

The Bathroom Manufacturers Association (BMA) is the lead trade association for manufacturers of bathroom products in the UK and has launched a “water-efficient product” labelling scheme. The scheme acts as a guide to selecting products for use in bathrooms.

<http://water-efficiencylabel.org.uk/default.asp>

Enhanced Capital Allowances Scheme: the Water Technology List

The Enhanced Capital Allowance (ECA) Scheme enables businesses to claim 100% first-year capital allowances on investments in technologies and products that encourage sustainable water use. Businesses are now able to write off the whole cost of their investment against their taxable profits for the period during which they make the investment. As part of this scheme, a list of water-efficient technologies that qualify can be found on the ECA water technology list website.

www.eca-water.gov.uk/

Water Regulations Advisory Scheme (WRAS)

The Water Regulations Advisory Scheme (WRAS) is the UK water industries’ scheme to promote knowledge of

UK water regulations and byelaws and approve fittings and appliances that comply with these. It encourages consistent interpretation and enforcement for the prevention of waste, undue consumption, misuse, erroneous measurement or contamination of water.

All WRAS-approved products or materials (which will normally bear the “WRAS-Approved Product” or “WRAS-Approved Materials” logos) have been tested and have been found to comply with the Water Supply (Water Fittings) Regulations 1999 (as amended) and the Scottish Water Byelaws 2004.

WRAS approval should be sought on all procured fixtures and fittings.

www.wras.co.uk/

Waterwise

Waterwise is an independent, not-for-profit organisation that receives funding from the UK water industry and from sponsorship and consultancy work. In England, it sits on the Government’s Water Saving Group alongside the water industry and regulators. Waterwise’s website provides guidance on water-efficient appliances, including a database of water-efficient washing-machines and dishwashers. Waterwise also awards the Waterwise Marque to products which are deemed to save water.

www.waterwise.org.uk/

11 Available support for auditing

Advanced Demand Side Management (ADSM)

OGCbuying.solutions (an executive agency of the Office of Government Commerce (OGC) in the Treasury) has negotiated a framework contract with ADSM.

ADSM can assist with the following:

- Compare a facility's water usage with that of similar organisations.
- Obtain help and advice to reduce consumption.
- Implement water-saving measures.
- Have the facility's entire water system and bills monitored and managed.
- Fast-track savings and meet government environmental targets.

www.adsm.com/

Envirowise

Envirowise delivers a government-funded programme of free, confidential advice to UK businesses. This assistance enables companies to increase profitability and reduce environmental impact.

www.enviro-wise.co.uk/site/uk/content-folder/homepage

National Water Conservation Group

The mission of the NWCG is to stimulate and inform debate about how to achieve the efficient use of water in the UK.

www.waterwise.org.uk/pages/national-water-conservation-group.html

Water UK

Water UK is the representative body for the UK water industry. It can advise on which water and sewerage companies provide local services.

www.water.org.uk/

12 Audit structures

GPs' surgeries and health clinics

In almost all cases, water use in GPs' surgeries and health clinics will be domestic. Normally there will be WCs, basin taps, a kitchen tap and a dishwasher. In some cases, there may also be a shower, a urinal and fittings for outside use (for example, water for a garden).

The following steps should be considered in a water management plan:

Note

These are best practice guidelines only.

- **Choose a designated water champion.** This should be someone with an overview of the building's facilities, someone in charge of financial management or someone who is keen on the subject.
- **Communicate with all staff (including contract cleaners and washroom maintenance contractors).** Communication could be written or ideally face-to-face, and should explain that a water management plan is being established and that all staff will be kept informed and are also welcome to contribute.
- **Gather information.** This should include plans of the building showing plumbing and fixtures, water and sewerage bills, how water is used in the building (who waters the plants, how often is the dishwasher used, does anyone use the shower, where do the cleaners fill their buckets etc), and any alternative sources of water (bottled water for catering, a water cooler in the waiting room, rainwater butt for the garden).
- **Carry out a water audit.**
- **Assess other water issues** such as what the level of flood risk is, how to deal with flooding, and what to do if the water supply is interrupted.
- **Draw up a management plan.** This should include plans of where all water fittings, plumbing and drains are. It should list all appliances and fittings with a guide to their water consumption (WC flush volume, dishwasher usage per wash etc). It should then suggest actions such as fitting cistern displacement devices or sourcing flood-prevention measures, with an outline of potential costs and savings.
- **Discuss the management plan** with all staff and take action where appropriate.
- **Keep the plan up to date.**

Hospitals

- **Choose a designated water champion.** This should be someone with an overview of the building's facilities, someone in charge of financial management or someone who is keen on the subject. This person should have the support of the senior management.
- **Communicate with all staff (including clinicians, contract cleaners and washroom maintenance contractors).** Communication could be written or ideally face-to-face, and should explain that a water management plan is being established and that all staff will be kept informed and are also welcome to contribute.
- **Gather information.** This should include plans of the site showing water meters, plumbing and fixtures, water and sewerage bills, the main areas of water use and drainage. It should include any existing water reports, input from staff who use water, and copies of contracts that specify water use for landscape maintenance or cleaning.
- **Walk the site** to check information and plans against reality.
- **Carry out a water and wastewater audit.**
- **Assess other water issues** such as what the level of flood risk is, how to deal with flooding and what to do if water supply is interrupted.
- **Draw up a management plan.** This should include plans of where all water fittings, plumbing and drains are. It should provide a breakdown of water and wastewater issues for each part of the site, allocating a reference code to each piece of water-using equipment and providing details of its water use, its condition and information on what it does. The plan should

then suggest actions for each area of the site with an outline of potential costs and savings.

- **Keep the plan up to date.**
- **Discuss the management plan** with all staff and take action where appropriate.

13 Case Study 1: Gwent Healthcare NHS Trust: water-leakage detection initiative

The energy team at Gwent Healthcare NHS Trust, South Wales, manages over 70 properties including nine hospitals, among them being the Royal Gwent (600 beds) and Nevill Hall (400 beds). The Trust spends over £4 million per year on electricity, gas and water, which is billed from over 300 meter points.

Managers at County Hospital, Griffithstown, had long suspected there might have been a water leak on the site, as the water bills appeared excessive compared to hospitals of a similar size. As a result, they decided to install a water-leakage detection system. This involved the use of a meter logger and Internet-based water-meter monitoring and analysis, which helped to track water usage.

When the results were analysed using the water-meter-monitoring website, they discovered that there was a very high level of water consumption during the early hours of the morning – a period when water demand should have been low.

It soon became apparent there was a leak of 4 m³ per hour on the site. Trial holes were excavated at positions where the leak was thought to be. Because of the high number of unrecorded service tees off the site's water main, the leak initially proved difficult to locate. When it was eventually found and repaired, water demand on the site was reduced by a factor of 10.

This initiative has saved the Gwent Healthcare NHS Trust over £66,000 on its annual water bill. It will receive an additional £66,000 in sewerage rebates from its water supplier for the last two years. These savings will be used to invest in additional energy-saving technology.

Internet-based metering services can analyse and identify abnormal utility consumption, correct excessive usage or leakage and provide daily reporting to facilities management. In most cases, the payback period is less than two years. In the case of Griffithstown, payback was less than one month, with immediate positive cash-flow benefit from the second month onwards in reduced water charges.

14 Case study 2: St Thomas' Hospital water audit

Introduction

There are seven strategic health authorities within the Thames Water area and numerous hospitals of differing types and sizes. Thames Water carried out a thorough water review at each of the seven largest London hospitals to understand where water savings could be achieved, estimate how much water these actions could save, and identify the best location and type of water savings devices to be installed.

The following summarises the findings of Thames Water's water audit of St Thomas' Hospital.

St Thomas' Hospital

St Thomas' Hospital is part of the Guy's and St Thomas' NHS Trust. The individual buildings range considerably in age.

Trending

The hospital has put in place some good water management practices (for example the closed-loop cooling of MRI scanners), and St Thomas' water consumption appears to be better than average.

The hospital has lower than average consumption of around 342,500 m³/year when compared with its expected use of between 247,500 m³ and 517,500 m³ of water per annum (based on the benchmarking data given in [Tables 2–4](#) of Chapter 5, and assuming there will be 750,000 patient contacts per year).

Periodic checks of actual normalised consumption against benchmarking data and the previous year's performance are worthwhile completing. Without monitoring and comparing water consumption against historical levels and consumption patterns, it is impossible to know whether current consumption is typical or excessive, or whether the hospital is getting more or less efficient. Trending also allows the unusual to be rapidly identified – particularly leaks or losses.

Guidance on how to trend a site's water consumption is given in 'Steps to sustainable water use'.

Cost

St Thomas' is currently on the Thames Water major-user tariff and is charged with a separate volumetric rate for water supply and wastewater disposal.

Water use at the time of the audit cost the hospital approximately £206,860 and £116,826 for water and wastewater volumetric charges, respectively, and an additional £47,444 in standing charges – a total of £371,130 per annum.

Given the large losses of steam and water from evaporation in the cooling towers (estimated at 30,000 m³/year and 9000 m³/year, respectively), the 10% non-return-to-sewer allowance currently assumed appeared low. However, no accurate data existed on which to base any correction. Thames Water recommended that flowmeters be inserted at relevant points so that non-return-to-sewer could be more accurately evaluated.

Water distribution plan

It was recommended that the site's water distribution plan be maintained and developed to show meters, submeters and valve work in order to assist in water management and provide a process-mapping tool to understand water use on site.

Recommendations to reduce water use

Pressure

There is a variable pressure supply throughout one of the buildings – the lower the floor, the greater the water pressure. With an estimated 4 m between floors, the static head from the 13 floors to the ground floor is some 50 m or 5 bar. Several taps were tested (mixer tap, full-bore cold supply) in the building as follows:

- upper floor – 15 L/min;
- lower floor – 40 L/min;
- basement – 60 L/min.

Apart from the flow on the top floor, the flows through other taps are excessive.

Even though taps are not often used fully open, any overpressure results in unnecessary water consumption by taps (and showers).

It was recommended that pressure-reducing valves be fitted to reduce pressure to points of use to the more usual 1.5–2.5 bar. However, because of the pipework configuration, it was acknowledged that this could prove to be difficult. An alternative could be to restrict the maximum flow by adjusting the isolation ball-valves to taps, where they are fitted.

Leakage

As the site is fed by multiple water mains and has a large network of internal and underground pipes, a leakage survey was undertaken. The only significant water leak identified during the water review was estimated at around 120 L per hour (over 1000 m³/year).

Steam loss

Several significant steam releases were occurring across the site. It was thought that traps or steam-release valves were not seating correctly. Apart from the obvious water loss, the value of this loss is really in the treatment of, and energy in, the steam.

An approximate assessment of its value can be made at £1 per cubic metre for the raw water (including softening and boiler water treatment costs) and approximately £11 in energy costs (assuming 732 kWh to raise 1 m³ water from 15°C to 100°C, and converting it to steam with useful energy at 1.5p per kWh). This gives a value of approximately £12 per cubic metre of water used for steam generation – the cost of a steam loss is therefore reasonably high.

Evaporation from the hydrotherapy pool

The hydrotherapy pool is approximately 18 m³. The water temperature is held at 35°C and has a pH value of 7.28 during sessions. It is not equipped with a cover.

Evaporation losses from this pool are typically around 5–10 mm per day – hence, annual evaporation loss may be 22–44 m³/year. While this may not appear much water, its value is high because of the energy loss. Each litre of water that evaporates wastes 1.3 kWh of energy; assuming useful energy costs at 1.5p per kWh, this represents a loss of £21 per cubic metre.

Fitting a pool cover will virtually eliminate evaporation when the pool is unoccupied, saving water and energy. Assuming this is 16 hours per day, savings will be around £300–£600 per annum.

Baths/showers

It was recommended that, when showers are provided, high-performance low-flow types are used and that, to avoid water running to waste while the correct temperature is obtained (and for safety), thermostatic controls are used. Apart from the savings in water, there are also significant energy savings, as most of the water saved will be hot or warm.

WCs

The volume of water used for flushing can be minimised by adjusting the internal ball-cock to reduce filling volume to a minimum, fitment of a cistern volume adjuster (cistern devices) or replacement of the toilet (new units have a maximum flush of 6 L).

Urinals

It was recommended that the urinals be fitted with a passive infrared (PIR) automatic sensor flush control of the “cumulative” type – that is, it counts the number of people using the facility and flushes after, for example, 25 users. Such a device would eliminate flushing during low use, weekends and at night (except a hygiene flush) such that the amount of water saved will be approximately 1051 m³ per annum.

Savings can be notable, with payback for each unit generally obtained within 9–12 months.

It was also recommended that all urinals fitted during refurbishment be specified with PIR-type flush controls.

Taps

By far the greatest problem was the excessive flow due to high pressure on lower floors (see above). Tap regulators can be fitted to reduce the flow of water. In the case of hot water taps, energy savings will also result. Regulators can reduce the flow of water by up to 50%.

Break tanks and overflows

Overflows from break tanks and toilet cisterns should be visible so that if an overflow occurs it is easy to detect – a hidden overflow could be running for years without detection. A minor overflow (estimated as a 3 mm stream) will lose approximately 350 m³ water per year.

Potential savings

There are still several opportunities to reduce water consumption, some of which will also reduce energy consumption, allowing significant financial savings to be made.

Practical actions to achieve water savings have been identified in Table A1.

Table A1 Potential savings

Opportunity		Action	Potential saving (m ³ /annum)	Cost saving ^a (£/annum)	Estimated payback
Immediate low-cost actions	Hydrotherapy pool	Minimise evaporation by fitting simple cover when not in use	33	450	Moderate
	Urinal flush control	Fit sensor-type flush control to existing urinals	2,180	2,137	9–12 months
	Toilet cistern flush	Adjust ball-cock to reduce flush by 250 ml (or more)	500	489	Immediate
	Leaking taps	Repair leaking tap in the sterile services department	1,000	980	Immediate
	Steam losses	Maintain/repair release valves, traps etc	2,242	26,846	Rapid
	Endoscopy RO overflow	Replace two small ball-cock units with one larger one to avoid jamming of floats	1,576	1,544	Immediate
	Condensate losses	Fix leaks (appeared to require simple gland tightening)	30	75	Immediate
	Leaking pipes	Investigate and repair leak	1,000	980	Immediate
	Reduce distribution pressure	Install pressure-reducing valves (PRVs) as appropriate (or adjust isolation/flow regulation valves to taps)	8,076 ^b	7,915	Not calculated
Medium-term actions	Still cooling water	Replace once-through softened water with recirculating chiller or cooling-tower feed water. Alternatively, buy in distilled water	585	570	Moderate or intermediate
	Condensate return	Investigate current efficiency and improve collection and return	5,800	14,500	High
	Blowdown cooling	Cool blowdown via a heat exchanger – not simple dilution cooling with fresh water	182	450	Immediate
	Reuse reverse osmosis reject	Investigate scope for collecting reject water from boiler water RO unit (and others), storing it and using for a low-grade use	700	15,386	High but long-term
Total			15,828	72,322	

Notes:

Savings are combined estimations from separate building audits, summarised as net potential savings for the entire hospital.

a. Annualised cost estimated based on current tariffs. Note these are also year-on-year savings.

b. This figure could well be much higher than this

Appendix 4 – Governance Structure

1.0 Application of the Policy

1.1 Application

The Water Systems Safety Policy shall apply to all Domestic Hot Water, (DHW) and Domestic Cold Water, (DCW) systems, Water-Dispensing Equipment as well as defined, 'At Risk Water-carrying Systems' across all NHSGGC Premises, (hereafter referred to as 'Water Systems' in this Policy).

1.2 Objective

The objective of this policy is to ensure safe and effective control of Water Systems throughout NHSGGC Premises in order to minimise the risk from water borne Pathogens and maintain water quality in all NHSGGC Premises.

2.0 Introduction

2.1 Pathogens

Most microorganisms are harmless to healthy individuals and are commonly found on people, in the environment and in water supplies or on birds and other animals in the vicinity of NHSGGC Premises. As these microorganisms are 'naturally occurring'; they can readily find their way into Water Systems. Some of these microorganisms however, if given the appropriate conditions, can cause, or lead to, infections that may put some people at risk of serious harm.

2.2 Statutory Instruments and Mandatory Guidance

The variety and extent of water-related Statutory Instruments, mandatory and other approved Guidance, Policies, Operational Procedures/Protocols and good industry practice (Hereafter referred to as 'Statutory Instruments & Mandatory Guidance' in this Policy), emphasises the essential nature of safely managing Water Systems. The applicable Statutes and Guidance are referenced in Appendix 2.

2.3 Statutory Responsibilities

NHSGGC has a statutory obligation to identify and effectively control risks to protect patients, Staff and members of the public arising from Water Systems within NHSGGC Premises.

2.4 Competence

NHSGGC will maintain a formal training programme for nominated key staff to ensure those appointed to devise strategies and carry out control measures are appropriately informed, instructed, trained and assessed to competently undertake their Roles & Responsibilities (See Appendix 1).

2.5 Penalties for Compliance Failures

Failures in compliance with 'Statutory Instruments & Mandatory Guidance' responsibilities may attract prosecution by Enforcing Authorities, (e.g. The Health & Safety Executive). Prosecutions may be 'Corporate', against the organisation, but

could also be 'Personal', brought against individual members of Staff. Penalties for prosecution may take the form of fines and/or imprisonment.

NHSGGC take their Statutory and Mandatory responsibilities and over-arching duty of care to its patients, staff and others seriously and will employ appropriate measures and sanctions where required to address failures to meet these duties in line with existing policy arrangements.

3.0 Duty of Care

3.1 Awareness of Responsibilities

NHSGGC recognises that it has a moral and ethical duty of care for the safety of patients and others, particularly those whom may have an elevated susceptibility to infection because of their increased vulnerability caused by underlying health factors and/or the suppression of their personal immune defences caused by their illness.

3.2 Discharging NHSGGC's Duty of Care

NHSGGC will discharge its Duty of Care through rigorous compliance with all relative 'Statutory Instruments & Mandatory Guidance'.

3.3 Essential Participation in Water Safety

Water safety within NHSGGC can only be achieved by every member of Staff actively contributing to a concerted 'team effort' and the risk to patients' safety will be compromised by people failing in their statutory responsibilities, by not following, or incorrectly applying the 'Statutory Instruments & Mandatory Guidance'.

It is essential therefore, that each Staff group and every individual in NHSGGC actively participates and applies procedures designed to reduce risks arising from Pathogens in Water Systems in NHSGGC.

4.0 Roles and Responsibilities

4.1 General Responsibilities

The active participation of all NHSGGC Staff members is essential to protect patients, Staff and members of the public from risks arising from Water Systems.

4.2 Key Personal Responsibilities

The 'Statutory Instruments & Mandatory Guidance' relating to water safety, identifies key roles with specific responsibilities to ensure the effective application of recommended and mandatory procedures.

Specific individual and group responsibilities of each of these key roles, along with nominated posts for each of these key roles, are provided in Appendix 1 of this Policy. Named individuals appointed to these roles are detailed in the respective site procedures and Written Scheme(s). Each named individual or group must familiarise

themselves with the dimensions of their specific and corporate responsibilities relating to water safety in NHSGGC.

It should be noted that the responsibilities noted in this policy may not be exhaustive and it is recommended that individuals refer to the 'Statutory Instruments & Mandatory Guidance' at Appendix 2 for a deeper understanding of their responsibilities.

5.0 Reporting

5.1 Monitoring & Review

Control Measures relating to water safety in NHSGGC shall be systematically examined, monitored and reviewed by designated teams and individuals carrying specific or delegated managerial responsibilities.

5.2 Formal Periodic Reports

Formal periodic reports on Water Systems will be presented by:

- I. Various Sector-located Groups and appointed key individuals, (e.g. RPs(W)) to their respective Sector Water Systems Safety Groups (SWSSG);
- II. Groups and appointed key individuals within the Sector management structure of The Health and Safety Department, the E&F and Infection Prevention & Control Service via the SWSSG to the NHSGGC Board Water Systems Safety Group (BWSSG);
- III. Either or both co-Chairs of the BWSSG, on behalf of the Group, to the Board Infection Control Committee (BICC) and the Health & Safety Forum;
- IV. The Chair of the BICC on behalf of the BICC to the Corporate Management Team (CMT) (including the Chief Executive, (CE)).

5.3 Governance Structure

The Governance Structure is shown in Appendix 4 of this policy.

6.0 Risk Reduction

6.1 Assessment

Following any assessment of the risks arising from Water Systems, Control Measures will be implemented, when appropriate and reasonably practicable.

6.2 Risk Reduction

Control Measures may include Risk Reduction Strategies to reduce the likelihood and/or severity of patient infections.

SWSSGs are responsible for ensuring that a multi disciplinary approach is taken to risk reduction within the Board at local level.

7.0 Operational Arrangements

7.1 Written Scheme & Operational Procedures

Control measures are set out in NHSGGC's Water Safety Written Scheme and Operational Procedures, designed to establish a system of control which shall be rigorously applied by specifically trained staff within a recommended, formally appointed structure for the safe management and governance oversight of Water Systems. The Written Scheme and operational procedure records are held in the Board's smart sheet document management service and are available for review on request.

7.2 Planned Maintenance

Water Systems throughout NHSGGC are subject to a routine planned maintenance system, managed and controlled via NHSGGC's proprietary Computer Aided Facilities Management (CAFM) System, FMfirst ®, by designated Maintenance Supervisors.

8.0 Testing

In keeping with the current HSE guidance, testing for Legionella will be carried out within NHSGGC as follows:-

8.1 High Risk Clinical Areas

A list of High Risk Clinical Areas, where immuno-compromised patients may be cared for, has been determined by the NHSGGC Lead Infection Control Doctor, (ICD), and these are designated as 'high-risk clinical areas'. This list can be found at Appendix 3, clause A.3.8.

Clinical High Risk Areas will be specifically identified within the various site-specific Written Schemes.

8.2 Engineering Risk Areas

Due to the 'age' of some of NHSGGC's current property portfolio, it is recognised that there are some installations that may present a high risk of contamination by Pathogens due to the Water System's distribution configuration. Where this is the case, the system will be defined as an Engineering High Risk and a testing programme will be implemented and rigorously maintained.

The Engineering High Risk areas and Other High Risk Areas can be found at Appendix 3 – clauses A3.1.5 & A.3.11 and will be specifically identified within the various site-specific 'Written Schemes'.

9.0 Pseudomonas

9.1 Pseudomonas Guidance

NHSGGC will seek to reduce the risk from Pseudomonas in its Water Systems by complying with the Water (Scotland) Group's guidance document titled, 'Guidance for Neonatal Units, (NNUs) (levels 1, 2 & 3), adult and paediatric Intensive Care Units, (ICUs), in Scotland to minimise the risk of Pseudomonas Aeruginosa infection from water', (version 2.3 dated May 2018), produced by Health Facilities Scotland, Health Protection Scotland.

10.0 Action on Identification or Incident

10.1 Action if an environmental organism is identified as a source of an infection incident (not Legionella);

Guidance as per the NHS GGC IPC Environmental Organisms Standard Operating Procedure (SOP) (<https://www.nhsggc.org.uk/media/253288/environmental-organisms-in-high-risk-areas-sop-final-v1-november-2018.pdf>) and the Pseudomonas SOP (<https://www.nhsggc.org.uk/media/255146/sop-pseudomonas-aeruginosa-v3-amended-july-2019.pdf>) will be followed to assess and action incidents involving these water related organisms.

Where an incident team is set up to investigate a trigger, the Outbreak SOP (https://www.nhsggc.org.uk/media/245201/outbreak-sop-final-version-oct-2017-_2_.pdf) will be followed.

10.2 Action if Legionella Bacteria is Identified in Water Systems;

If a water sample, a reading of Legionella bacteria is shown to be present routine precautions and control measures designed to eliminate the Legionella bacteria will be applied. If there is still Legionella bacteria detected in a follow-up sample still, then a record of this incident will be made on NHSGGC's Datix reporting and recording system in line with the NHSGGC's Incident Management Policy and Procedure.

The RP(W) and AP(W) in the Directorate of E&F must be copied into all Datix reported incidents.

10.3 Action if Legionella Bacteria is the Source of an Infection Incident

When it can be demonstrated that an infection incident has originated in a Water System, the AP(W) must ensure that a review and investigation is carried out and formally recorded and reported to the RP(W) and ICD.

These incidents should be reviewed as a 'significant adverse event' as per the Incident Management Policy and Procedure.

10.4 Review of Infection Incident Reports

In order to ensure the implementation and effectiveness of this policy all incident reports relating to water management should be reviewed regularly by the Sector Estates Manager, RP(W), and the site ICD and periodically reported to, and reviewed by, the SWSSG.

10.5 Clinical Incident

In the event that two or more clinical cases are potentially linked to water quality, a problem assessment group or IMT will be initiated by the nominated ICD. In certain circumstances, e.g. Legionella serogroup 1, a single hospital acquired case would warrant an IMT.

10.6 Outbreak

Where water quality is confirmed as the source of clinical cases and the IMT assess the incident using the Hospital Infection Incident Assessment Tool (HIIAT) as HIIAT red or amber, this will be reported to HPS using the Hospital Infection Incident Reporting Template, (HIIORT) and recorded on the service risk register by the nominated ICD.

11.0 Audit

11.1 Monitoring of Policy Effectiveness

The application and effectiveness of this policy throughout the organisation shall be monitored by the Health and Safety Department reporting via the BWSSG and the Estates & Facilities Senior Management Team (SMT).

11.2 Policy Review

This Policy will normally be reviewed annually, but certainly within every 3 year period. The Policy will be revised at the time of review or as a result of any changes in or to the 'Statutory Instruments & Mandatory Guidance'.

Appendix 1A1 Roles and ResponsibilitiesA1.1 Chief Executive – Duty Holder (Water) (DH(W)).

The Chief Executive has overall executive responsibility with accountability to NHSGGC's Board for all safety, health and risk matters in NHSGGC. The Chief Executive, (CE), is the designated Duty Holder (Water) (DH(W)), for NHSGGC.

The responsibilities of the DH(W) include:

- Assuring NHSGGC's Board, via the Board's Corporate Management Team (CMT), that the Board's statutory responsibilities relating to Water Systems are being safely and appropriately discharged;
- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the DH(W) responsibilities;
- Ensuring the provision of adequate resources to safely maintain and to effectively manage and control identified risks arising from the Water Systems in the NHSGGC estate to an appropriate level;
- Ensuring the implementation of and adherence to the NHSGGC Water Systems Safety Policy at all levels within the organisation;
- Formally appointing the Designated Person (Pseudomonas) and Designated Person (Water) (and their deputies) to assist in the execution of these responsibilities, who for NHSGGC are respectively, the Infection Control Manager and the Director of Estates & Facilities.

A1.2 Board Corporate Management Team (CMT).

The CMT will have managerial oversight of water-related issues and responsibility for communication in sufficient detail to NHSGGC Health Board, giving assurance that Water Systems are being safely and effectively managed and that the Board's related Statutory obligations are being appropriately discharged.

The CMT membership is:

CEO (CHAIR);
 Medical Director (BICC Chair);
 COO – Acute;
 Corporate Communications;
 Chief Officer– HSCP;
 Director of Public Health;
 Director of eHealth;
 Directors of HSCPs;
 Director of HR;
 Co – Partnerships;
 Employee Director;
 Director of Nursing;
 Co HSCP;
 Director of Estates & Facilities;
 Head of Corporate Governance;
 Director of Finance;

Executive Director HSCP Glasgow.

The water-related responsibilities of the CMT include:

- Having managerial oversight of, and assuring NHSGG&C Health Board that the Board's statutory responsibilities relating to Water Systems are being safely and appropriately discharged;
- Individually participate in appropriate periodic training to establish and maintain personal knowledge and a level of expertise allowing the efficient discharge responsibilities related to this Policy;
- Ensuring, through the Board's management structure, the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems examples 'Guidance' at 3 and adherence to the NHSGGC Water Systems Safety Policy at all levels within NHSGGC;
- Liaising with the DP(P) and the DP(W) to ensure the Boards Water Systems Policy is understood and applied across all areas of the Board;
- With support from the DP(P) and the DP(W), formulate a Water Systems Safety Compliance Programme, (for both passive and active measures) in existing properties and for new capital projects;
- Performing governance oversight on behalf of the Board by reviewing the effectiveness of operational arrangements. The CMT will be advised on this by the BICC with contributions from the DP(P) and the DP(W) via the BWSSG.

A1.3 Director of Estates & Facilities, (DE&F) – Designated Person (Water) (DP(W)).

The DE&F has delegated executive responsibility with accountability to DH(W) for all safety, health and risk matters relating to Water Systems in NHSGGC, with the exception of the responsibilities delegated to the Designated Person (Pseudomonas), at clause A1.4 . The DE&F is the DP(W) for NHSGGC.

The Responsibilities of the DP(W) include:

- Identify and ensure the efficient formal record of Water System risks and raising those considered appropriate from the BWSSG to the CMT via the BICC;
- Provide formal reports from the BWSSG to assure the Health Board via the CMT that the Board's statutory responsibilities relating to Water Systems are being safely and appropriately discharged;
- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the DP(W) responsibilities;
- Identify to the CMT a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems in the NHSGGC estate, to an acceptable level;
- Effectively manage the resources provided to safely maintain and to manage and control identified risks, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGGC Water Systems Safety Policy at all levels within the Directorate of E&F;
- Ensuring that E&F Staff, through the Directorate management structure, are fully aware and appropriately trained in the Statutory and Mandatory

requirements and standards for the provision and maintenance of Safe Water Systems;

- Ensuring, with the RP(P), that the Water System Safety Policy is regularly reviewed and updated;
- Co-Chair the NHSGGC BWSSG;
- Formally appoint a 'Deputy Designated Person (Water)', (DDP(W)), who will deputise for the DP(W) as required, undertaking delegated responsibilities;
- Formally appoint (or delegate the responsibility) the Responsible Person (Water) at sector level (Sector Estates Manager), Deputy Responsible Person(s) (Water) at site level (Site Maintenance/Estates Manager) and the Authorised Person (Water), (AP(W)), at site level within the E&F Directorate management structure.

A1.4 Infection Control Manager – Designated Person (Pseudomonas) (DP(P)).

The ICM has delegated executive responsibility with accountability to DH(W) for all Pseudomonas related safety, health and risk matters in Water Systems within NHSGGC premises. The ICM is the Designated Person (Pseudomonas), (DP(P)), and will be supported by the Board's designated ICD.

The DP(P) shall be responsible for:

- Identifying and ensuring the efficient, formal record of Water System risks related to Pseudomonas and raising those considered appropriate from the BWSSG to the CMT via the BICC;
- Provide formal reports to assure the CMT that the Board's statutory responsibilities relating to the control of Pseudomonas, (and other Pathogens), in Water Systems are being safely and appropriately discharged;
- Participate in a training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the DP(P) responsibilities;
- Identify to the CMT a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems in the NHSGGC Premises to an acceptable level;
- Effectively use the resources provided to manage and control identified risks arising from the control of Pseudomonas, (and related pathogenic bacteria), in Water Systems in the NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to the control of Pseudomonas, (and related pathogenic bacteria), in Water Systems, examples of, 'Guidance' in Appendix 3, in particular, the 'Guidance for Neonatal Units (NNU's) (levels 1, 2 & 3) adult and paediatric Intensive Care Units ICU's in Scotland', and adherence to the NHSGGC Water Systems Safety Policy at all levels in Infection Control Teams in all NHSGGC Premises;
- Ensuring that Infection Control Teams, (ICTs), are fully aware of, and are appropriately trained in statutes and appropriate guidance on Legionella control matters and the minimisation of the risk of Pseudomonas Aeruginosa, (and other Pathogens), infection arising from Water Systems in NHSGGC Premises;
- Ensuring, with the DP(W) that the Water System Safety Policy is regularly reviewed and updated;
- Co-Chair the BWSSG;

- Formally appoint a 'Deputy Designated Person (Pseudomonas)', who will deputise for the DP(P) as required, undertaking delegated responsibilities;
- Appointing in writing the Responsible Person(s) (Pseudomonas) at sector level. These shall be the relevant ICDs.

A1.5 Assistant Director of Estates & Capital Planning, (ADE&CP) – Deputy Designated Person (Water) (DDP(W)).

The ADE&CP will be appointed by the DE&F and in his absence has delegated executive responsibility with accountability to DH(W) for all safety, health and risk matters relating to Water Systems in NHSGGC, with the exception of the responsibilities delegated to the Designated Person (Pseudomonas), at clause A1.4 .

He will carry out all the duties and responsibilities of the DP(W) as stated in clause A1.3 above.

A1.6 Head of Corporate Estates (HCE) – Senior Corporate Responsible Person (Water) (SCR(P(W))).

The Head of Corporate Estates (HCE) has responsibilities delegated by the DP(W) with accountability to the DDP(W) and the DP(W) for all safety, health and risk matters relating to Water Systems across NHSGGC Premises involved in minor works. The HCE is also the lead in ensuring SCART compliance, audits and training is in place with respect to Water Safety.

The SCR(P(W)) is responsible for:

- Identifying and ensuring the efficient formal record of Sector related Water System risks and raising those considered appropriate to the DDP(W) & DP(W) and the BWSSG;
- Provide formal compliance reports to the BWSSG assuring the DDP(W) & DP(W) that the Board's statutory responsibilities relating to Water Systems, in respective Sectors, are being safely and appropriately discharged;
- Supporting the HOE in the production of policies & procedures to ensure the quality of water in NHSGGC Premises is safely maintained;
- Appoint a Water Safety Authorising Engineer (AE) to support NHSGG&C on all issues relating to Water;
- Working with the AE(W) and SORP appoint Responsible Persons Water (RP(W)) across all sectors;
- Appoint Authorised Persons Water (AP(W)) across NHSGG&C on the recommendation of the Authorising Engineer Water (AE(W));
- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the RP(W) responsibilities;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems and adherence to the NHSGGC Water Systems Safety Policy at all levels within the Sector of the Directorate of E&F;
- Ensuring that Corporate estates staff are fully aware and appropriately trained in the 'Statutory Instruments & Mandatory Guidance' and standards for the provision and maintenance of safe Water Systems;
- Ensure that adaption's and modifications to installations in NHSGGC Premises are not implemented without prior review and formal, prior approval by the

RP(W), AP(W) and/or AE(W) as required relating to the scale, complexity and/or associated risk;

- Liaise closely with other professionals to ensure consistency in application of Control Measures and other procedures designed to allow legislative and statutory compliance, comprehensively in all NHSGGC Premises.
- Compliance Audit Duties;
 - Ensuring a robust annual water audit regime is in place;
 - Ensuring that Written Schemes and Risk Assessments are in place and reviewed regularly;
 - Ensure the e-SCART tool is populated and updated regularly with action plans in place, where required;
 - Ensuring operational procedures are carried out and appropriately recorded;
 - Ensuring formal records are kept of all Water Systems and their purpose;
 - Ensure an Annual report on Water Compliance across NHSGG&C is delivered to the DP(W).

A1.7 Head of Operational Estates (HOE) – Senior Operational Responsible Person (Water) (SORP(W)).

The Head of Operational Estates (HOE) has responsibilities delegated by the DP(W) with accountability to the SORP(W) & DP(W) for all safety, health and risk matters relating to Water Systems across NHSGGC Premises.

The SORP(W) is responsible for:

- Identifying and ensuring the efficient formal record of Sector related Water System risks and raising those considered appropriate to the DDP(W) DP(W) and the BWSSG;
- Provide formal reports to the BWSSG assuring the DDP(W) & DP(W) that the Board's statutory responsibilities relating to Water Systems, in respective Sectors, are being safely and appropriately discharged
- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the RP(W) responsibilities;
- Identify to the BWSSG a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems to an acceptable level;
- Effectively manage and control the resources provided to safely maintain and to effectively manage and control identified risks arising from the Water Systems in the Sector of the NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems and adherence to the NHSGGC Water Systems Safety Policy at all levels within the Sector of the Directorate of E&F;
- Ensuring that Sector estates staff, through the Directorate management structure, are fully aware and appropriately trained in the 'Statutory Instruments & Mandatory Guidance' and standards for the provision and maintenance of safe Water Systems;
- Ensuring the effective maintenance of engineering controls installed for the purposes of controlling water systems;

- Ensuring that Written Schemes and risk assessments are in place and reviewed regularly;
- Devising and maintaining procedures to ensure the quality of water in NHSGGC Premises is safely maintained;
- Ensuring operational procedures are carried out and appropriately recorded;
- Ensuring formal records are kept of all Water Systems and their purpose, giving locations recording and maintaining within the Board's CAFM System;
- Ensure that adaption's and modifications to installations in NHSGGC Premises are not implemented without prior review and formal, prior approval by the RP(W), AP(W) and/or AE(W) as required relating to the scale, complexity and/or associated risk;
- Liaise closely with other professionals to ensure consistency in application of Control Measures and other procedures designed to allow legislative and statutory compliance, comprehensively in all NHSGGC Premises.

A1.8 Assistant Head of Operational Estates – Responsible Person (Water) (RP(W)).

The Assistant Head of Operational Estates (AHOE) has responsibilities delegated by the DP(W) with accountability to the SORP(W) & DP(W) for all safety, health and risk matters relating to Water Systems in their respective Sectors of NHSGGC Premises.

The RP(W) is responsible for:

- Identifying and ensuring the efficient formal record of Sector related Water System risks and raising those considered appropriate to the SORP(W) & DP(W) and the BWSSG;
- Provide formal reports to the BWSSG assuring the SORP, DDP(W) & DP(W) that the Board's statutory responsibilities relating to Water Systems, in respective Sectors, are being safely and appropriately discharged
- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the RP(W) responsibilities;
- Identify to the BWSSG a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems to an acceptable level;
- Effectively manage and control the resources provided to safely maintain and to effectively manage and control identified risks arising from the Water Systems in the Sector of the NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems and adherence to the NHSGGC Water Systems Safety Policy at all levels within the Sector of the Directorate of E&F;
- Ensuring that Sector estates staff, through the Directorate management structure, are fully aware and appropriately trained in the 'Statutory Instruments & Mandatory Guidance' and standards for the provision and maintenance of safe Water Systems;
- Ensuring the effective maintenance of engineering controls installed for the purposes of controlling water systems;
- Ensuring that Written Schemes and risk assessments are in place and reviewed regularly;
- Devising and maintaining procedures to ensure the quality of water in NHSGGC Premises is safely maintained;

- Ensuring operational procedures are carried out and appropriately recorded;
- Ensuring formal records are kept of all Water Systems and their purpose, giving locations recording and maintaining within the Board's CAFM System;
- Ensure that adaptations a modifications to installations in NHSGGC Premises are not implemented without prior review and formal, prior approval by the RP(W), AP(W) and\or AE(W) as required relating to the scale, complexity and\or associated risk;
- Liaise closely with other professionals to ensure consistency in application of Control Measures and other procedures designed to allow legislative and statutory compliance, comprehensively in all NHSGGC Premises.

A1.9 Authorising Engineer (Water), (AE(W)).

The AE(W), is appointed in writing by the SCRP and is employed independently of NHS Boards. The AE(W) acts as an independent professional advisor to NHSGGC with a brief to provide services in compliance with relative 'Statutory Instruments & Mandatory Guidance', and particularly with Scottish Health Technical Memoranda (SHTM) 04-01, mandatory guidance for the NHS in Scotland.

The AE(W) will have specialist knowledge of large scale domestic and commercial hot and cold water services installations including incoming supplies and Other Risk Systems as detailed in Appendix 3 and in particular, those installations for which an Authorised Person (Water) will assume responsibility for.

The AE(W) is free to comment on the organisational risk base and give guidance on the numbers of AP(W) required across all NHSGGC properties.

The AE(W)'s main duties will include:

- To be a formal Assessor, making recommendations to the SCRP(W) for the appointment of AP(W) in terms of skills, training and site familiarity;
- Formally monitoring the performance of NHSGGC against 'Statutory Instruments & Mandatory Guidance', particularly, ACoP L8, HSG274 (Parts 1,2 & 3), and SHTM 04-01 guidance;
- The provision of a formal, annual 'L8 Audit' to the SCRP(W).

A1.10 Senior General Manager – Property and Capital Planning – Deputy Responsible Person (Water), (DRP(W)).

The Senior General Manager – Property & Capital Planning, (P&CP), will be formally appointed as a DRP(W), at Board level by the SCRP(W);

The DRP(W) responsibilities include the following within any Capital Projects:

- Identifying and ensuring the efficient formal record of any related Water System risks and raising those considered appropriate to the RP, SCRP(W) & SCRP(W);
- Provide formal reports where required assuring the SORP(W), SCRP(W) & DP(W) that the Board's statutory responsibilities relating to extensions to, and refurbishments of Water Systems, are being safely and appropriately discharged;

- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the DRP(W) responsibilities;
- Identify to the SORP(W), SCRP(W) & DP(W) a risk-based prioritisation of the necessary resources required to effectively manage and control identified risks arising from the need to safely design, manufacture, install, alter or develop Water Systems in all new works in NHSGGC Premises, to an acceptable level;
- Effectively manage and control the resources provided to control risk in Water Systems in all new works in NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGG&C Water Systems Safety Policy at all levels within the P&CP, section of the Directorate of E&F, particularly those related to guidance in SHTM 04-01, HSG274 Parts 1, 2 & 3 and ACoP L8 and compliance to this guidance shall be formally certified by the design engineer;
- Ensuring that P&CP Staff, are fully aware and appropriately trained in the statutory and mandatory requirements and standards for the design and provision of safe Water Systems;
- Ensuring that any new works undertaken or refurbishment within existing NHSGGC Premises shall comply with the requirements of this Policy and the Written Scheme and Operational Procedures for managing water safety including particularly, The Control of Legionella, Hygiene, 'Safe' Hot Water, Cold Water and Drinking Water Systems';
- Ensuring that installations, adaptations a modifications carried out under capital project developments are approved and signed off by the AE(W), & respective senior AP(W);
- Ensuring all works are formally commissioned and handed over to the respective Site Manager Operational Estates (SMOE) in compliance with the handover protocol for water as identified in the Written Scheme;
- Ensuring that all physical and control interfaces with existing Water Systems for new and refurbishment works shall be safely designed, installed, commissioned in a pre-planned, safe and effective manner and formally agreed and signed off by the RP(W) and AP(W), particularly any derogations or deviations from applicable Guidance;
- Ensuring that any works which will affect an operational water service will be discussed and formally agreed with the estates AP(W) prior to arranging that work.

A1.11 Site Manager Operational Estates (SMOE) – Deputy Responsible Person (Water), (DRP(W)).

The Site Manager Operational Estates shall be formally appointed in writing by the SCRP(W).

The DRP(W) responsibilities include:

- Identifying and ensuring the efficient formal record of relative Water System risks and raising those considered appropriate to the RP(W) and the SWSSG;
- Provide formal reports to the SWSSG assuring the RP(W) that the Board's statutory responsibilities relating to Water Systems, in relative NHSGGC Premises, are being safely and appropriately discharged;

- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the DRP(W) responsibilities;
- Identify to the SWSSG a risk-based prioritisation of necessary resources required to effectively manage and control risks arising from the management of Water Systems to an acceptable level;
- Effectively manage and control identified risks arising from the Water Systems in the relative locations of the NHSGG&C Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this policy), and adherence to the NHSGG&C Water Systems Safety Policy at all levels within the relative locations of the Directorate of E&F;
- Ensuring that E&F Staff, managed by the DRP(W), through the Directorate management structure, are fully aware of their personal roles and responsibilities and appropriately trained in the statutory and mandatory requirements and standards for the management of safe Water Systems;
- Ensuring Water Systems are operated in accordance with the current guidance, and with the assessed risk of the individual systems under the control of the DRP(W);
- Ensuring water system maintenance records are maintained and kept up-to-date;
- Regularly checking maintenance records;
- Ensuring all work is completed in accordance with the NHSGGC Operational Procedures.

A1.12 Acute Services Directors, HSCP Directors and Corporate Division Directors.

NHSGGC Directors and Senior Managers, play an essential role in the safe management of Water Systems, actively ensuring and demonstrating that water safety is embedded within the culture of the organisation.

The responsibilities of Directors and Senior Managers include:

- Identifying and ensuring necessary formal records are maintained relating to Policies and Operational Procedures for Water Systems and raising any potential risks relating to Water Systems to the RP(W) and the SWSSG;
- Participate in training to maintain personal knowledge and a level of expertise allowing the efficient discharge of Director and Senior Manager responsibilities;
- Effectively manage and control identified risks arising from the Water Systems in the relative NHSGGC Premises areas of responsibility, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' and Operational Procedures related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGG&C Water Systems Safety Policy at all levels within the relative NHSGGC Premises areas of responsibility;
- Ensuring that Staff, managed by the Director and Senior Manager are fully aware of their personal roles and responsibilities and appropriately trained in the statutory and mandatory requirements and standards for the management and operation of safe Water Systems;

- Facilitating Staff to allow their timely attendance at Water Safety training at the appropriate frequency, as per the NHSGGC Water Safety Policy and Operational Procedures which underpin this Policy;
- Ensuring Water Systems are operated in accordance with the current guidance, and NHSGGC Operational Procedures;
- Ensuring Water Systems records, including Staff training records, are monitored and kept up-to-date;
- Supporting the DP(W) and DP(P) in the development of the Board's overall strategy in relation to the safe management and operation of NHSGGC Water Systems and for ensuring and demonstrating implementation within their areas of responsibility;
- Monitor and actively and effectively correct situations where inaction or actions by Staff put themselves and/or others at risk from actual or potential water safety incidents.

A1.13 Heads of Service (HoS), Departmental Managers (DMs), Clinical Managers (CMs) and Senior Charge Nurses (SCNs)

All managers and SCNs have a responsibility in the safe management of Water Systems, actively ensuring and demonstrating that water safety is sufficiently embedded in their departments, and for the safe, day to day management of facilities, Staff or services, and/or premises.

Water safety responsibilities that include:

- Familiarise themselves with the NHSGGC Water Safety Policy and local control measures including any water risk assessments for their area(s) of responsibility;
- Ensuring that persons in the department, clinic or ward are fully aware of their responsibilities and duties in respect of Water Safety, in particular, the action required of them should the area be defined as High Risk, listed in the site-specific Water Safety Written Scheme and Operational Procedures;
- Ensure that persons in the department, clinic or ward are fully aware of the 'Infrequently Used Outlets' definitions and Operating Procedure which underpins the NHSGGC Water Safety Policy;
- Actively promoting Water Safety within the department or ward by maintaining good housekeeping within the department or ward at all times, ensuring that any flushing or documentation as described in the Water Safety Written Scheme and Operational Procedures documentation is completed on time ;
- Responding appropriately to any water safety concerns of persons in the department, clinic or ward;
- Encouraging their staff and themselves to promptly report any breaches in the water system, such as water ingress, leaks etc. to estates;
- Nominating a responsible person to complete the Monthly 'Infrequently Used Outlets' Audit for each area, forwarding a copy to the Site Maintenance/Estates Manager, thereby assisting NHSGGC to consistently comply with its statutory and mandatory obligations;
- Ensuring that action is taken on a daily basis to address any access issues identified within the Cleaning Compliance Checklist Sign Off documentation retained in the Facilities Folder;
- Liaising with the Estates Department as required.

A1.14 Authorised Person (Water) (AP(W)).

The AP(W), has the key operational role and will be specifically qualified, trained and experienced to allow the efficient discharge of their responsibilities. AP(W) will be recommended by the AE(W) for appointment by the SCRP(W).

Important elements of an AP(W) role are the comprehensive maintenance of formal records and the necessary quality of service and maintenance of systems to ensure their safety and integrity.

The AP(W) will also be responsible for establishing and formally appointing a sufficient number of Competent Persons (Water), (CP(W)), to carry out maintenance and operational Procedures on Water Systems.

The AP(W) will ensure all CPs(W) managed by the AP(W) are suitably trained, competent NHSGGC employees or formally engaged competent contractor(s).

Larger sites may require more than one AP(W). Where more than one AP(W) is operating on a site, the SCRP(W) will appoint one AP(W) to take a lead role, ensuring effective, clear, unambiguous communications, with the purpose of safely discharging responsibilities and avoiding confusion and duplication.

The responsibilities of the AP(W) include:

- Identifying and ensuring the efficient formal record of relative Water System risks and raising those considered appropriate to the RP(W);
- Provide formal reports to the RP(W) assuring the SORP, SCRP & DP(W) that the Board's statutory responsibilities relating to Water Systems, in relative locations, are being safely and appropriately discharged;
- Participate in a recommended training programme to maintain personal knowledge and a level of expertise allowing the efficient discharge of the AP(W) responsibilities;
- Identify to the RP, SORP & SCRP a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems to an acceptable level;
- Effectively manage and control identified risks arising from the Water Systems in the relative locations of the NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGGC Water Systems Safety Policy at all levels within the relative locations of the Directorate of E&F;
- Ensuring that estates staff, managed by the AP(W), through the Directorate management structure, are fully aware and appropriately trained in the 'Statutory Instruments & Mandatory Guidance' and standards for the provision and maintenance of safe Water Systems;
- The AP(W) will also be able to demonstrate:
 - Their application through familiarisation with the system(s) they are responsible for and the successful completion of an appropriate professional course;
 - A sufficient level of professional experience;
 - Evidence of knowledge and skills relating to Water Systems;

- Review and formally approve all new minor installations, adoptions and modifications prior to implementation, engage with RP (W), and/or AE(W) as required with respect to the scale, complexity and/or associated risks.

A2.0 Statutes & Guidance

Compliance with Statutory Instruments, (SIs), is Compulsory and will take primacy. The SIs and Mandatory Guidance, (listed below), should be consulted for more comprehensive information and guidance.

- Health & Safety at Work, etc. Act 1974
- The Management of Health and Safety at Work Regulations 1999 & (Amendment) Regulations 2006
- The Control of Substances Hazardous to Health Regulations (COSHH) 2002 7 (Amendment) Regulations 2004
- Health & Safety Commission's Approved Code of Practice & Guidance L8, (ACOP L8), 'Legionnaires' disease: The control of Legionella bacteria in water systems'. (Forth Edition 2014)
- Public Health (Infectious Diseases) Regulations 1998 si1988 No 1550 (s.155)
- NHS Estates - Scottish Health Technical Memoranda 04-01 (SHTM 04-01)
- The Chartered Institute of Building Services Engineers (CIBSE) - Technical Memorandum (TM13), Minimising the Risk of 'Legionnaires' Disease'
- Water Regulations Advisory Scheme - Water Supply (Water Fittings) Regulations 1999
- Water Regulations Advisory Scheme (WRAS 2005) - Water Fittings and Materials Directory
- The Water Supply (Water Fittings) (Scotland) Byelaws 2014
- Water Supplies (Scotland) Regulations 2014
- Food Safety Act 1990
- BS 8580: 2019 Water quality. Risk assessments for Legionella control. Code of practice
- BS 6700; 2006, 'Design, Installation, Testing & Maintenance of services supplying water for domestic use within buildings & their cartilages - Specification'
- BS EN 806-1; (2012) 'Specification for installations inside buildings conveying water for human consumption'
- BS 1710; 2014 Specification for Identification of Pipelines and Services
- BS EN 12671: 2009 Chemicals used for treatment of water intended for human consumption. Chlorine dioxide. British Standards Institution, 2009
- Thermostatic Mixing Valve Manufacturers Association - Recommended Code of Practice for Safe Water Temperatures
- Guidance for neonatal units (NNU's) (levels 1, 2 & 3) adult and paediatric intensive care units ICU's in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water
- HSG274 Legionnaires' Disease Technical Guidance
- Date of publication: 2014 ISBN: 978 0 7176 6635 5 Series code: HSG274
- HSG274 is split into three distinct parts as follows:
- HSG274 Legionnaires' disease: Technical guidance Part 1:
- The control of legionella bacteria in evaporative cooling systems
- HSG274 Legionnaires' disease: Technical guidance Part 2:
- The control of legionella bacteria in hot and cold water systems
- HSG274 Legionnaires' disease: Technical guidance Part 3:
- The control of legionella bacteria in Other Risk Systems

- CEL 08 (2013) water sources and potential risk to patients in high risk units – revised guidance

A 3.0 Definitions and Acronyms

A3.1 Definitions

A3.1.1 Cleaning Compliance Checklist

A formal checklist of cleaning within the ward or department, signed off by the person in charge of the area confirming satisfaction of compliance with cleaning standards

A3.1.2 Control Measures

Considered, deliberate strategies, actions and activities employed, or stopped, which are designed to remove, reduce or mitigate risks that may diminish the ability to deliver safe and effective healthcare

A3.1.3 Domestic Cold Water

Cold potable water, either from water mains or storage systems, used by people for washing and drinking etc.

A3.1.4 Domestic Hot Water

Tempered Water for use by people for washing and bathing

A3.1.5 Engineering High Risk areas

The 'Engineering High Risk areas' are:

- In Water Systems treated with biocides, e.g. CLO₂;
- Where water is stored;
- In water systems where the control levels of the treatment regime, e.g. temperature or disinfectant concentrations are not being consistently achieved or frequently vary from recommended levels;
- In water systems suspected or identified in a case or outbreak of Legionellosis where it is probable the Incident Control Team will require samples to be taken for analysis;
- In water systems suspected or identified in a case or outbreak linked to other potential water borne Pathogens where it is probable the Incident Control Team will require samples to be taken for analysis;
- In areas which have been identified within the current Water Safety Risk Assessment as being of a risk.

A3.1.6 Facilities Folder

A folder, held as documentary evidence and a formal record of procedures at ward / department level.

A3.1.7 Guidance / Mandatory Guidance

Guidance, policies, operational procedures/protocols and good industry practice etc. Guidance can be varied if the variation can be defended. Where Guidance is 'mandated' within general industry and in the NHS in Scotland, it becomes 'Mandatory Guidance' and may be referred to within Statutory Instruments as an 'Approved Code of Practice (ACOPs).

A3.1.8 High Risk Clinical Areas

The list of High Risk Clinical Areas determined by the NHSGGC Lead ICD, where immuno-compromised patients may be cared for, are as follows;

- Transplant units
- ICU\PICU
- NICU\SCBU
- Haemato-oncology units
- Cardiology
- Coronary Care

A3.1.9 Infrequently Used Outlets

Water Systems' appliances that are used infrequently, as defined in 'Infrequently Used Outlets' definitions and Operating Procedure.

A3.1.10 NHSGGC Premises

All Hospitals, Health Centres, Clinics and other Properties, General Practice, Dental and other Surgeries, owned and or operated by NHSGGC where healthcare is delivered/provided to patients.

A3.1.11 Other Risk Systems

The following locations, systems and items of plant will have specific Control Measures applied to reduce the risk of infection.

- ultrasonic humidifiers/foggers
- spray humidifiers
- air washers, wet scrubbers, particle and trivial gas scrubbers
- water softeners
- emergency showers, eyebaths and face wash fountains
- sprinkler and hose reel systems
- spa pools
- whirlpool baths
- hydrotherapy pools
- birthing pool
- horticultural misting systems
- vehicle washers including automatic washers for cars, buses, lorries and railway rolling stock
- powered dental equipment
- fountains and decorative water features including those on display for sale
- non-disposable nebulisers used for respiratory therapy
- industrial effluent treatment plants
- irrigation systems
- fire, dust and odour suppression systems
- clinical wash-handbasins, drain outlets and connections
- wet drainage sump
- chilled beams
- cardiac heaters / coolers
- ECMO

A3.1.12 Outbreak SOP

The NHS GGC Outbreak SOP is a document which provides a definition of an outbreak /incident and recommended actions. The actions include when to set up an incident meeting, who should be invited (including external expertise) and a sample agenda. It also provides guidance on communications within the HB and to the Scottish Government.

A3.1.13 Pathogens

Microorganisms that are, or may become, harmful to people.

A3.1.14 Risk Reduction Strategies

Risk Reduction strategies/procedures can include, but are not limited to:

- Policy awareness and implementation;
- Risk assessment both generic and specific;
- Training, e.g. WH001 Legionella Management HTM 04-01 and WH003 Legionella Control within Hot and Cold Water Systems used in NHSGGC for APs(W), DRP(W), RP(W) etc.;
- The development, approval and implementation of local procedures;
- Reporting and recording;
- Evaluating effectiveness of risk reduction strategies/procedures;
- Reviewing in the light of experience, e.g. looking at incident investigations and inspection reports. Do they show improvement?;
- Re-train Staff if required, reading available policies, strategies and procedures;
- Review clinical and workplace risk assessments after reports of any adverse events;
- Implementation of risk reduction strategies as defined by the findings of the risk assessment for the NHSGGC buildings;
- Implementation of a formal review and/or audit process of the risk reduction procedures;
- Implementation of contractor audit and review procedures;
- Review and update Written Scheme and water action plan every 2 years or following material system amendments/change of use.

A3.1.15 Sector

A designated area of NHGGC that is a recognised Sector of NHSGGC Premises.

A3.1.16 Staff

People employed by NHSGGC on various contracts and will include locum, bank, volunteers etc.

A3.1.17 Statutory Instruments

Laws, regulations etc. that have legal standing and are applied by enforcing authorities.

A3.1.18 Water Systems

All domestic hot and cold water systems, water-dispensing equipment as well as defined, 'at risk' water-carrying systems across all NHSGGC premises.

A3.1.19 Water Dispensing Equipment

Equipment or machinery dispensing water, in all forms and states, for consumption and or use by people, e.g. Water coolers, Ice-making machines etc.

A3.1.20 Written Scheme & Operational Procedures

A document written to record and communicate, in detail, how responsibilities relating to the safe operation and management of Water Systems will be discharged and will describe who will have responsibilities for their safe and effective implementation

A3.2 Acronyms:

ACoP

Approved Code of Practice

ADP(W)

Acting Designated Person (Water)

AE(W)	Authorising engineer (Water)

1.0 Application of the Policy

1.1 Application

The Water Systems Safety Policy shall apply to all Domestic Hot Water, (**DHW**) and Domestic Cold Water, (**DCW**) systems, Water-Dispensing Equipment as well as defined, 'At Risk Water-carrying Systems' across all NHSGGC Premises, (hereafter referred to as 'Water Systems' in this Policy).

1.2 Objective

The objective of this policy is to ensure safe and effective control of Water Systems throughout NHSGGC Premises in order to minimize the risk from water borne Pathogens and maintain water quality in all NHSGGC Premises.

2.0 Introduction

2.1 Pathogens

Most microorganisms are harmless to healthy individuals and are commonly found on people, in the environment and in water supplies or on birds and other animals in the vicinity of NHSGGC Premises. As these microorganisms are 'naturally occurring'; they can readily find their way into Water Systems. Some of these microorganisms however, if given the appropriate conditions, can cause, or lead to, infections that may put some people at risk of serious harm.

2.2 Statutory Instruments and Mandatory Guidance

The variety and extent of water-related Statutory Instruments, mandatory and other approved Guidance, Policies, Operational Procedures/Protocols and good industry practice (Hereafter referred to as 'Statutory Instruments & Mandatory Guidance' in this Policy), emphasise the essential nature of safely managing Water Systems. The applicable Statutes and Guidance are referenced in **Appendix 1**.

2.3 Statutory Responsibilities

NHSGGC has a statutory obligation to identify and effectively control risks to protect patients, Staff and members of the public arising from Water Systems within NHSGGC Premises.

2.4 Competence

NHSGGC will maintain a formal training programme for nominated key staff to ensure those appointed to devise strategies and carry out control measures are appropriately informed, instructed, trained and assessed to competently undertake their Roles & Responsibilities **Appendix 2**.

2.5 Penalties for Compliance Failures

Failures in compliance with 'Statutory Instruments & Mandatory Guidance' responsibilities may attract prosecution by Enforcing Authorities, (e.g. The Health & Safety Executive). Prosecutions may be 'Corporate', against the organisation, but could also be 'Personal', brought against individual members of Staff. Penalties for prosecution may take the form of fines and/or imprisonment.

NHSGGC take their Statutory and Mandatory responsibilities and over-arching duty of care to its patients, staff and others seriously and will employ appropriate measures and sanctions where required to address failures to meet these duties in line with existing policy arrangements.

3.0 Duty of Care

3.1 Awareness of Responsibilities

NHSGGC recognises that it has a moral and ethical duty of care for the safety of patients and others, particularly those whom may have an elevated susceptibility to infection because of their increased vulnerability caused by underlying health factors and/or the suppression of their personal immune defences caused by their illness.

3.2 Discharging NHSGGC's Duty of Care

NHSGGC will discharge its Duty of Care through rigorous compliance with all relative 'Statutory Instruments & Mandatory Guidance'.

3.3 Essential Participation in Water Safety

Water safety within NHSGGC can only be achieved by every member of Staff actively contributing to a concerted 'team effort' and the risk to patients' safety will be compromised by people failing in their statutory responsibilities, by not following, or incorrectly applying the 'Statutory Instruments & Mandatory Guidance'.

It is essential therefore, that each Staff group and every individual in NHSGGC actively participates and applies procedures designed to reduce risks arising from Pathogens in Water Systems in NHSGGC.

4.0 Roles and Responsibilities

4.1 General Responsibilities

The active participation of all NHSGGC Staff members is essential to protect patients, Staff and members of the public from risks arising from Water Systems.

4.2 Key Personal Responsibilities

The 'Statutory Instruments & Mandatory Guidance' relating to water safety, identifies key roles with specific responsibilities to ensure the effective application of recommended and mandatory procedures.

Specific individual and group responsibilities of each of these key roles, along with nominated posts for each of these key roles, are provided in [Appendix 2](#) of this Policy. Named individuals appointed to these roles are detailed in the respective site procedures and Written Scheme(s). Each named individual or group must familiarise themselves with the dimensions of their specific and corporate responsibilities relating to water safety in NHSGGC.

It should be noted that the responsibilities noted in this policy may not be exhaustive and it is recommended that individuals refer to the 'Statutory Instruments & Mandatory Guidance' in [Appendix 1](#) for a deeper understanding of their responsibilities.

5.0 Reporting

5.1 Monitoring & Review

Control Measures relating to water safety in NHSGGC shall be systematically examined, monitored and reviewed by designated teams and individuals carrying specific or delegated managerial responsibilities.

5.2 Formal Periodic Reports

Formal periodic reports on Water Systems will be presented by:

- I. Various Sector-located Groups and appointed key individuals, (e.g. **RP(W)**) to their respective Sector Water Systems Safety Groups (**SWSSG**);
- II. Groups and appointed key individuals within the Sector management structure of The Health and Safety Department, Estates, Facilities and Infection Prevention & Control Service via the **SWSSG** to the NHSGGC Board Water Systems SafetyGroup (**BWSSG**) e.g minutes from **SWSSG** to **BWSSG** and **AICC**;
- III. Either or both co-Chairs of the **BWSSG**, on behalf of the Group, to the Board Infection Control Committee (**BICC**) and the Health & Safety Forum;
- IV. The Chair of the **BICC** on behalf of the **BICC** to the Corporate Management Team (**CMT**) (including the Chief Executive, (**CE**)).
- V. Local monthly minuted meetings between Estates and Microbiology should be arranged to review 'out of specs'.

6.0 Risk Reduction

6.1 Assessment

Following any assessment of the risks arising from Water Systems, Control Measures will be implemented, when appropriate and reasonably practicable. The water safety risk assessment program will be reviewed at each Board Water Safety Group Meeting. All new or refurbished properties will have a full Risk Assessment undertaken. NHSGG&C Acute sites (including our large partnership/HSCP) sites where there are in/outpatients will be risk assessed every 2 years and all other sites shall be risk assessed every 5 years unless there has been modifications carried out to the water installation or a significant change in the use of the building. Compliance will maintain this list.

6.2 Control Measures

Control Measures may include Risk Reduction Strategies to reduce the likelihood and/or severity of patient infections. SWSSGs are responsible for ensuring that a multi disciplinary approach is taken to risk reduction within the Board at local level.

As part of the risk of the risk reduction process, Infection Control will consider the permanent fitting of point of use filters in specific areas as per SHTM04-01

7.0 Operational Arrangements

7.1 Written Scheme & Operational Procedures

The Written Scheme and operational procedure records for each site are designed to establish a system of control which shall be rigorously applied by specifically trained staff within a recommended, formally appointed structure for the safe management and governance oversight of Water Systems. The Written Scheme and operational procedure records for each site are held in the Board's smart sheet document management service and are reviewed annually.

7.2 Planned Maintenance

Water Systems throughout NHSGGC are subject to a routine planned maintenance system, managed and controlled via NHSGGC's proprietary Computer Aided Facilities Management (CAFM) System, FMfirst ®, by designated Estates Supervisors and Managers.

8.0 Testing

In keeping with the current HSE guidance, testing for Legionella will be carried out within NHSGGC as follows:-

8.1 High Risk Clinical Areas

A list of High Risk Units at risk of legionella or pseudomonas and where immuno-compromised patients may be cared for, has been determined by ARHAI Scotland Guidance and these are designated as 'high-risk clinical areas'. This list can be found in **Appendix 3**, clause A.3.1.8.

Clinical High Risk Areas in relation to water will be specifically identified within the various site-specific Written Schemes.

8.2 Other sampling

Based on risk assessment and agreed through appropriate water management governance for operational, capital or minor works projects there may be a requirement for the sampling of other bacteria and a specific thresholds which are acceptable for these. There may be also a requirement agreed for ongoing monitoring.

8.3 Engineering Risk Areas

Due to the 'age' of some of NHSGGC's current property portfolio, it is recognised that there are some installations that may present a high risk of contamination by Pathogens due to the Water System's distribution configuration. Where this is the case, the system will be defined as an Engineering High Risk and a testing programme will be implemented and rigorously maintained.

The Engineering High Risk areas and Other High Risk Areas can be found in **Appendix 3** – clauses A3.1.5 & A.3.11 and will be specifically identified within the various site-specific 'Written Schemes'.

8.4 Governance Structure

The Governance Structure is shown in **Appendix 4** of this policy.

9.0 Pseudomonas

9.1 Pseudomonas Guidance

NHSGGC will seek to reduce the risk from Pseudomonas in its Water Systems by complying with the Water (Scotland) Group's guidance document titled, 'Guidance for Neonatal Units, (NNUs) (levels 1, 2 & 3), adult and paediatric Intensive Care Units, (ICUs), in Scotland to minimise the risk of Pseudomonas Aeruginosa infection from water', (version 2.3 dated May 2018), produced by Health Facilities Scotland, Health Protection Scotland.

10.0 Action on Identification of bacteria in a water system or Clinical Incident

10.1 Action above agreed thresholds

Reference of full details can be found in the GG&C Sampling Procedure. If bacteria is shown to be present above thresholds routine precautions and control measures designed to eliminate the bacteria will be applied. An incident record form (004) will be created listing actions taken and by whom. Sampling will be carried out as per agreed sampling procedure e.g. minimum of 3 not detected or within parameters for the specific bacteria. **ICD** will consider other precautions e.g. outlet to be placed out of use, patient moved etc.

The **LAP(W)** should provide at minimum monthly summary of current out of specs and actions taken to the **RP(W)**, **DRP(W)**, **Microbiology** and **ICD** colleagues and supply full details within an agreed Teams folder.

10.2 Action if an environmental organism is identified as a source of an infection

Guidance as per the NHS GGC IPC Environmental Organisms Standard Operating Procedure (SOP) (<https://www.nhsggc.org.uk/media/253288/environmental-organisms-in-high-risk-areas-sop-final-v1-november-2018.pdf>) and the Pseudomonas SOP (<https://www.nhsggc.org.uk/media/255146/sop-pseudomonas-aeruginosa-v3-amended-july-2019.pdf>) will be followed to assess and action incidents involving these water related organisms.

Where an incident team is set up to investigate a trigger, outbreak SOP [Incident Management Process Framework V1 - NHSGGC](#) will be followed. Any incidents **HIAT** assessed will be reported nationally as per chapter 3 **NIPCM** as well as part of the reporting requirements for **IPCT**.

In the event of clinical cases are potentially linked to water quality, which is determined by ICD's as per Chapter 3 NIPCM, a problem assessment group or **IMT** will be initiated by the nominated **ICD**. In certain circumstances, e.g. Legionella serogroup 1, a single hospital health care associated case would warrant an **IMT** (refer to Chapter 3 NIPCM and the Incident Management Process Framework).

Where water quality is confirmed as the source of clinical cases and the **IMT** assess the incident using the Hospital Infection Incident Assessment Tool (**HIAT**) as **HIAT** red, amber or green this will be reported to **ARHAI** using the Hospital Infection Incident Reporting online reporting tool, (**HIORT**) and recorded on the service risk register by the nominated Clinical Service. Any that score red, amber or green in the **HIAT** assessment will be reported in the **HAIRT** which goes to clinical and care governance group, in addition a summary **HAIRT** is presented each time the NHS Board meets.

When it can be demonstrated that an infection incident has originated in a Water System, the **AP(W)** must ensure that a review and investigation is carried out and formally recorded and reported to the **RP(W)** and **ICD**. These incidents should be reviewed as a 'significant adverse event' as per the Incident Management Policy and Procedure.

11.0 Audit

11.1 Monitoring of Policy Effectiveness

The application and effectiveness of this policy throughout the organisation shall be monitored by the Health and Safety Department reporting via the **BWSSG** and the Estates & Facilities Senior Management Team (**SMT**).

11.2 Policy Review

This Policy will normally be reviewed annually, but certainly within every 3 year period. The Policy will be revised at the time of review or as a result of any changes in or to the 'Statutory Instruments & Mandatory Guidance'.

12.0 Appendices

Appendix 1 – A1.0 Statutes & Guidance

Compliance with Statutory Instruments, (SIs), is Compulsory and will take primacy. The SIs and Mandatory Guidance, (listed below), should be consulted for more comprehensive information and guidance **including but not limited to :-** .

- Health & Safety at Work, etc. Act 1974
- The Management of Health and Safety at Work Regulations 1999 & (Amendment) Regulations 2006
- The Control of Substances Hazardous to Health Regulations (COSHH) 2002 7(Amendment) Regulations 2004
- Health & Safety Commission's Approved Code of Practice & Guidance L8, (ACOP L8), 'Legionnaires' disease: The control of Legionella bacteria in water systems'.
- Public Health (Infectious Diseases) Regulations 1998 si1988 No 1550 (s.155)
- NHS Estates - Scottish Health Technical Memoranda 04-01 (SHTM 04-01)
- The Chartered Institute of Building Services Engineers (CIBSE) - Technical Memorandum (TM13), Minimising the Risk of 'Legionnaires' Disease'
- Water Regulations Advisory Scheme - Water Supply (Water Fittings) Regulations 1999
- Water Regulations Advisory Scheme (WRAS 2005) - Water Fittings and Materials Directory
- The Water Supply (Water Fittings) (Scotland) Byelaws 2014
- Water Supplies (Scotland) Regulations 2014
- Food Safety Act 1990
- BS 8580: 2019 Water quality. Risk assessments for Legionella control. Code of practice
- BS 6700; 2006, 'Design, Installation, Testing & Maintenance of services supplying water for domestic use within buildings & their cartilages - Specification'
- BS EN 806-1; (2012) 'Specification for installations inside buildings conveying water for human consumption'
- BS 1710; 2014 Specification for Identification of Pipelines and Services
- BS EN 12671: 2009 Chemicals used for treatment of water intended for human consumption. Chlorine dioxide. British Standards Institution, 2009
- Thermostatic Mixing Valve Manufacturers Association - Recommended Code of Practice for Safe Water Temperatures
- Guidance for neonatal units (NNU's) (levels 1, 2 & 3) adult and paediatric intensive care units ICU's in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water
- HSG274 Legionnaires' Disease Technical Guidance Date of publication: 2014 ISBN: 978 0 7176 6635 5 Series code: HSG274
 - o Legionnaires' disease: Technical guidance Part 1: Control of legionella bacteria in evaporative cooling systems
 - o Legionnaires' disease: Technical guidance Part 2: The control of legionella bacteria in hot and cold water systems
- Legionnaires' disease: Technical guidance Part 3: The control of legionella bacteria in Other Risk Systems.
- CEL 08 (2013) water sources and potential risk to patients in high risk units –revised guidance.

Appendix 2 – A2.0 Roles and Responsibilities

A2.1 Chief Executive – Duty Holder (Water) DH(W)

The Chief Executive has overall executive responsibility with accountability to NHSGGC's Board for all safety, health and risk matters in NHSGGC. The Chief Executive, (**CE**), is the designated Duty Holder (Water) **DH(W)**, for NHSGGC.

The responsibilities of the **DH(W)** include:

- Assuring NHSGGC's Board, via the Board's Corporate Management Team (**CMT**), that the Board's statutory responsibilities relating to Water Systems are being safely and appropriately discharged;
- Participate in a **Compliance defined** training programme **for this role** to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **DH(W)** responsibilities;
- Ensuring the provision of adequate resources to safely maintain and to effectively manage and control identified risks arising from the Water Systems in the NHSGGC estate to an appropriate level;
- Ensuring the implementation of and adherence to the NHSGGC Water Systems Safety Policy at all levels within the organisation;
- Formally appointing the Designated Person (Pseudomonas) **DP(P)** and Designated Person (Water) **DP(W)** (and their deputies) to assist in the execution of these responsibilities, who for NHSGGC are respectively, the Infection Control Manager and the Director of Estates.

A2.2 Board Corporate Management Team (CMT)

The CMT will have managerial oversight of water-related issues and responsibility for communication in sufficient detail to NHSGGC Health Board, giving assurance that Water Systems are being safely and effectively managed and that the Board's related Statutory obligations are being appropriately discharged.

Refer to CMT ToR for full membership.

The water-related responsibilities of the **CMT** include:

- Having managerial oversight of, and assuring NHSGG&C Health Board that the Board's statutory responsibilities relating to Water Systems are being safely and appropriately discharged;
- Individually participate in appropriate periodic training to establish and maintain personal knowledge and a level of expertise allowing the efficient discharge responsibilities related to this Policy;
- Ensuring, through the Board's management structure, the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems examples 'Guidance' at 3 and adherence to the NHSGGC Water Systems Safety Policy at all levels within NHSGGC;
- Liaising with the **DP(P)** and the **DP(W)** to ensure the Boards Water Systems Policy is understood and applied across all areas of the Board;
- With support from the **DP(P)** and the **DP(W)**, formulate a Water Systems Safety Compliance Programme, (for both passive and active measures) in existing properties and for new projects;
- Performing governance oversight on behalf of the Board by reviewing the effectiveness of operational arrangements. The **CMT** will be advised on this by the **BICC** with contributions from the **DP(P)** and the **DP(W)** via the **BWSSG**.

A2.3 Director of Estates and Facilities (DE) – Designated Person (Water) DP(W)

The **DP(W)** has delegated executive responsibility with accountability to **DH(W)** for all safety, health and risk matters relating to Water Systems in NHSGGC, with the exception of the responsibilities delegated to the Designated Person (Pseudomonas) **DP(P)**.

The Responsibilities of the **DP(W)** include:

- Identify and ensure the efficient formal record of Water System risks and raising those considered appropriate from the **BWSSG** to the **CMT** via the **BICC**;
- Provide formal reports from the **BWSSG** to assure the Health Board via the **CMT** that the Board's statutory responsibilities relating to Water Systems are being safely and appropriately discharged;
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **DP(W)** responsibilities;
- Identify to the **CMT** a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems in the NHSGGC estate, to an acceptable level;
- Effectively manage the resources provided to safely maintain and to manage and control identified risks, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGGC Water Systems Safety Policy at all levels within the Directorate of Estates;

Ensuring that Estates, through the Directorate management structure, are fully aware and appropriately trained in the Statutory and Mandatory requirements and standards for the provision and maintenance of Safe Water Systems;

- Ensuring, with the **RP(P)**, that the Water System Safety Policy is regularly reviewed and updated;
- Chair the NHSGGC **BWSSG (or nominated deputy)** as per SHTM requirements ;
- Formally appoint a **DDP(W)**, who will deputise for the **DP(W)** as required, undertaking delegated responsibilities;
- Formally appoint (or delegate the responsibility) to **RP(W)** at sector level, **DRP(W)** and **AP(W)** at site level and on larger sites also **LAP(W)**.

A2.4 Infection Control Director (ICD) – Designated Person (Pseudomonas) DP(P)

The Infection Control Director has delegated executive responsibility with accountability to **DH(W)** for all Pseudomonas related safety, health and risk matters in Water Systems within NHSGGC premises. The **ICD** is the Designated Person (Pseudomonas), **DP(P)**, and will be supported by the Board's designated **LICD**.

The **DP(P)** responsibilities are outlined in the pseudomonas guidance and include :

- Include *P. aeruginosa* from a blood culture as an alert organism via IC net from an adult or paediatric patient. Also include *P. aeruginosa* from any clinical specimen in a neonatal unit/Adults ICU as an alert organism via ICnet. IPCTs when assessing alert organisms be mindful that *P. aeruginosa* can be selected for by prior antibiotic usage.
- Ensure they can detect in real time any possible outbreak early through effective local surveillance and monitoring of numbers of cases over time. e.g automatic trigger alerts as defined by the NHSGGC Surveillance Review Group.
- Be able to facilitate early identification of possible source in collaboration with colleagues in estates and microbiology.
- Have a contingency plan for NNUs and ICUs to enable safe patient care to continue without direct patient/water contact, e.g. use of patient wipes and sterile water in neonatal units.
- Any local outbreak or incident should be assessed using the Hospital Infection Incident Assessment Tool (HIIAT) and reported to ARHAI if amber or red. In addition, if there is an active ongoing clinical incident, where the source is considered to be tap water, then ARHAI should also be informed regardless of the HIIAT.
- An assessment of the clinical practice and ongoing care of invasive devices, cleaning of patient equipment and usage of hand wash stations that could compromise patients during incidents or outbreaks.
- Review of cases each year to inform decision making around high risk areas and update the pseudomonas risk assessment yearly.
- Instruct at the discretion of the ICD/IMT water testing during incidents or outbreaks.
- Ensuring the implementation of all Guidance' related to the control of Pseudomonas, in particular, the 'ARHAI(2018) Guidance for Neonatal Units (NNU's) (levels 1, 2 & 3) adult and Paediatric Intensive Care Units ICU's in Scotland', and adherence to the NHSGGC Water Systems Safety Policy at all levels in Infection Control Teams in all NHSGGC Premises;
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **DP(P)** responsibilities;

A2.5 Assistant Director of Operational Estates, (ADOE) – Deputy Designated Person (Water) DDP(W)

The **DDP(W)** will be appointed by the **DP(W)** and in their absence have delegated executive responsibility with accountability to **DP(W)** for all safety, health and risk matters relating to Water Systems in NHSGGC, with the exception of the responsibilities delegated to the **DP(P)**., at **A2.4** .

The **DDP(W)** will carry out all the duties and responsibilities of the **DP(W)** as stated in **A2.3** above.

A2.6 Head of Corporate Estates (HCE) – Corporate Responsible Person (Water) CRP(W)

The Head of Corporate Estates (**HCE**) has responsibilities delegated by the **DP(W)** with accountability to the **DDP(W)** for all safety, health and risk matters relating to Water Systems across NHSGGC Premises involved in minor works. The HCE is also the lead in ensuring SCART compliance, audits and training is in place with respect to Water Safety.

The **CRP(W)** is responsible for:

- Identifying and ensuring the efficient formal record of Sector related Water System risks and raising those considered appropriate to the **DDP(W)** & **DP(W)** and the **BWSSG**;
- Identifying and ensuring the efficient formal record of any related Water System risks due to minor works projects and raising those considered appropriate to the **RP(W)**, **AE(W)** and **DDP(W)**.
- Unknown risks not apparent to design teams `during Minor Works Projects should also be highlighted during project scoping involving **AP(W)**'s and **AE(W)**.
- Provide formal compliance reports to the **BWSSG** assuring the **DDP(W)** & **DP(W)** that the Board's statutory responsibilities relating to Water Systems, in respective Sectors, are being safely and appropriately discharged;
- Supporting the **DP(W)** and **DDP(W)** in the production of policies & procedures to ensure the quality of water in NHSGGC Premises is safely maintained;
- Appoint a Water Safety Authorising Engineer **AE(W)** to support NHSGG&C on all issues relating to Water;
- Working with the **AE(W)** and **DDP(W)** appoint Responsible Persons Water **RP(W)** across all sectors;
- Appoint Authorised Persons Water **AP(W)** across NHSGG&C on the recommendation of the Authorising Engineer Water **AE(W)**;
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **DRP(W)** responsibilities;
- Ensuring that Corporate staff, are fully trained as **AP(W)** to ensure that delegated projects comply with all NHSGG&C policy and procedures. This is to ensure that those working on water systems, **AP(W)** are appropriately trained in the statutory and mandatory requirements and standards for the design and provision of safe Water Systems including :-
- Ensuring that any new works undertaken or refurbishment within existing NHSGGC Premises shall comply with the requirements of this Policy and the Written Scheme and Operational Procedures for managing water safety including particularly, The Control of Legionella, Hygiene, 'Safe' Hot Water, Cold Water and Drinking Water Systems';
- Ensuring all works are formally commissioned and handed over to the respective **LAP(W)** in compliance with the handover protocol for water as identified in the Written Scheme including but not limited to drawings, changes to schematics, WRAS approval documentation and modified or new risk assessment;
- Ensuring that all physical and control interfaces with existing Water Systems for new and refurbishment works shall be safely designed, installed, commissioned in a pre-planned, safe and effective manner particularly any derogations or deviations from applicable guidelines;

- Ensure, as **DRP(W)** that Corporate Estates modifications to installations in NHSGGC Premises can only be implemented following completion of **Form (025)**. This form should be completed by the Designer and then signed by **Designer, AP(W)P, DRP(W)P and LAP(W)**;
 - Formal handover to **LAP(W)** should be implemented via **Form (029)** Record form for acceptance of work to be conducted and confirmation of work completed on a water system; This form should be completed by **AP(W)P** and signed as accepted by **DH(W)** for **AP(W)P** and **LAP(W)**.
 - Included in **Form (029)** is the requirement to complete the Confirmation of work completed and acceptance section. This section should be signed by the **Designer, AP(W)P and LAP(W)**.
 - Liaise closely with other professionals to ensure consistency in application of Control Measures and other procedures designed to allow legislative and statutory compliance, comprehensively in all NHSGGC Premises;
-
- Compliance Audit Duties;
 - o Ensuring a robust annual water audit regime is in place;
 - o Ensuring that Written Schemes and Risk Assessments are in place and reviewed regularly;
 - o Ensure the e-SCART tool is populated and updated regularly with action plans in place, where required;
 - o Ensuring operational procedures are carried out and appropriately recorded;
 - o Ensuring formal records are kept of all Water Systems and their purpose;
 - o Ensure an Annual report on Water Compliance across NHSGG&C is delivered to the **DDP(W)** and **DP(W)**.

A2.7 Assistant Head of Operational Estates – Responsible Person (Water) RP(W)

The Assistant Head of Operational Estates (**AHOE**) has responsibilities delegated by the **DP(W)** and **DDP(W)** with accountability to the **DDP(W)** & **DP(W)** for all safety, health and risk matters relating to Water Systems in their respective Sectors of NHSGGC Premises. They will be nominated in writing by the **CRP(W)** and signed by the **DP(W)** and/or **DDP(W)** ;

The **RP(W)** is responsible for:

- Identifying and ensuring the efficient formal record of Sector related Water System risks and raising those considered appropriate to the **DDP(W)** & **DP(W)** and the **BWSSG**;
- Identifying and ensuring the efficient formal record of any related Water system risk due to Operational Estates projects and raising those considered appropriate to the **RP(W)**, **AE(W)** and **DDP(W)**.
- Unknown risks not apparent to design teams `during Minor Works Projects should also be highlighted during project scoping involving **AP(W)**'s and **AE(W)**.
- Provide formal reports to the **BWSSG** assuring the **CRP(W)**, **DDP(W)** & **DP(W)** that the Board's statutory responsibilities relating to Water Systems, in respective Sectors, are being safely and appropriately discharged
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **RP(W)** responsibilities;
- Identify to the **BWSSG** a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems to an acceptable level;
- Effectively manage and control the resources provided to safely maintain and to effectively manage and control identified risks arising from the Water Systems in the Sector of the NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensure risk assessments, schematics and drawing are supplied to **LRP(W)** to effectively manage and control the resources provided to control risk in Water Systems in all new works in NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGG&C Water Systems Safety Policy at all levels within Corporate Estates, particularly those related to guidance in SHTM 04-01, HSG274 Parts 1, 2 & 3 and ACoP L8 and compliance to this guidance shall be formally certified by the Designer;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems and adherence to the NHSGGC Water Systems Safety Policy at all levels within the Sector of the Directorate of Estates & Facilities;
- Ensuring that Sector estates staff, through the Directorate management structure, are fully aware and appropriately trained in the 'Statutory Instruments & Mandatory Guidance' and standards for the provision and maintenance of safe Water Systems;
- Ensuring the effective maintenance of engineering controls installed for the purposes of controlling water systems;

- Ensuring that Written Schemes and risk assessments are in place and reviewed regularly;
- Devising and maintaining procedures to ensure the quality of water in NHSGGC Premises is safely maintained;
- Ensuring operational procedures are carried out and appropriately recorded;
- Ensuring formal records are kept of all Water Systems and their purpose, giving locations recording and maintaining within the Board's CAFM System;
- Ensuring that all physical and control interfaces with existing Water Systems for new and refurbishment works shall be safely designed, installed, commissioned in a pre-planned, safe and effective manner particularly any derogations or deviations from applicable
- Liaise closely with other professionals to ensure consistency in application of Control Measures and other procedures designed to allow legislative and statutory compliance, comprehensively in all NHSGGC Premises;

A2.8 Authorising Engineer (Water), AE(W)

The **AE(W)**, is appointed in writing by the **CRP(W)** and is employed independently of NHS GG&C. The **AE(W)** acts as an independent professional advisor to NHSGGC with a brief to provide services in compliance with relative 'Statutory Instruments & Mandatory Guidance', and particularly with Scottish Health Technical Memoranda (SHTM) 04-01, mandatory guidance for the NHS in Scotland.

The **AE(W)** will have specialist knowledge of large scale domestic and commercial hot and cold water services installations including incoming supplies and Other Risk Systems as detailed in **Appendix 3** and in particular, those installations for which an Authorised Person (Water) will assume responsibility for.

The **AE(W)** is free to comment on the performance of the organization against the operational risk base.

The **AE(W)**'s main duties will include:

- To be a formal Assessor, making recommendations to the **CRP(W)** for the appointment of **AP(W)** in terms of skills, training and site familiarity;
- Formally monitoring the performance of NHSGGC against 'Statutory Instruments & Mandatory Guidance', particularly, ACoP L8, HSG274 (Parts 1,2 & 3), and SHTM 04-01 guidance;
- The provision of a formal, annual L8 Audit at all NHSGGC Acute sites including our large hospitals where there are in/outpatients and an audit every 3 years for all remaining sites.
Reporting of potential risks (operational and through potential improvements).

A2.9 Head of Capital Projects or nominated person/persons in Capital – Deputy Responsible Person (Water), DRP(W)P

The Head of Capital Projects or Deputy be formally appointed as a **DRP(W)**, by the **DP(W) or DDP(W)**. They will be nominated in writing by the **CRP(W)** and signed by the **DP(W)** and/or **DDP(W)**;

The **DRP(W)P** responsibilities include the following within any Infrastructure, Planning and Delivery (IPD) projects:

- Identifying and ensuring the efficient formal record of any related Water System risks due to projects and raising those considered appropriate to the **RP(W)**, **DP(W)** & **CRP(W)**;
- Unknown risks not apparent to design teams during Projects should also be highlighted during scoping involving **AP(W)'s and AE(W)**.
- Provide formal reports where required assuring the **RP(W)**, **DDP(W)** & **CRP(W)** that the Board's statutory responsibilities relating to extensions to, and refurbishments of Water Systems, are being safely and appropriately discharged;
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **DRP(W)** responsibilities;
- Ensuring that Property and Capital Planning Staff, are fully trained as **AP(W)P** to ensure that delegated projects comply with all NHSGG&C policy and procedures. This is to ensure that those working on water systems, **AP(W)P** are appropriately trained in the statutory and mandatory requirements and standards for the design and provision of safe Water Systems including :-
- Ensure risk assessments, schematics and drawing are supplied to **LRP(W)** to effectively manage and control the resources provided to control risk in Water Systems in all new works in NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGG&C Water Systems Safety Policy at all levels within Capital, particularly those related to guidance in SHTM 04-01, HSG274 Parts 1, 2 & 3 and ACoP L8 and compliance to this guidance shall be formally certified by the Designer;
- Ensuring that any new works undertaken or refurbishment within existing NHSGGC Premises shall comply with the requirements of this Policy and the Written Scheme and Operational Procedures for managing water safety including particularly, The Control of Legionella, Hygiene, 'Safe' Hot Water, Cold Water and Drinking Water Systems';
- Ensuring all works are formally commissioned and handed over to the respective **LAP(W)** in compliance with the handover protocol for water as identified in the Written Scheme including but not limited to drawings, changes to schematics, WRAS approval documentation and modified or new risk assessment;
- Ensuring that all physical and control interfaces with existing Water Systems for new and refurbishment works shall be safely designed, installed, commissioned in a pre-planned, safe and effective manner particularly any derogations or deviations from applicable guidelines;
- Ensure, as **DRP(W)P** that Capital works modifications to installations in

NHSGGC Premises can only be implemented following completion of **Form (025)**. This form should be completed by the Designer and then signed by **Designer, AP(W)P, DRP(W)P** and **LAP(W)**.

- Formal handover to **LAP(W)** should be implemented via **Form (029)** Record form for acceptance of work to be conducted and confirmation of work completed on a water system; This form should be completed by **AP(W)P** and signed as accepted by **DH(W)** for **AP(W)P** and **LAP(W)**.
- Included in **Form (029)** is the requirement to complete the Confirmation of work completed and acceptance section. This section should be signed by the **Designer, AP(W)P** and **LAP(W)**.
- Liaise closely with other professionals to ensure consistency in application of Control Measures and other procedures designed to allow legislative and statutory compliance, comprehensively in all NHSGGC Premises;

A2.10 Site Manager Operational Estates (SMOE) – Deputy Responsible Person(Water), DRP(W)

The Site Manager Operational Estates RP role shall be formally appointed in writing by the **CRP(W)**. They will be nominated in writing by the **CRP(W)** and signed by the **DP(W)** and/or **DDP(W)**;

The **DRP(W)** responsibilities include:

- Identifying and ensuring the efficient formal record of relative Water System risks and raising those considered appropriate to the **RP(W)** and the **SWSSG**;
- Provide formal reports to the **SWSSG** assuring the **RP(W)** that the Board's statutory responsibilities relating to Water Systems, in relative NHSGGC Premises, are being safely and appropriately discharged;
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **DRP(W)** responsibilities;
- Identify to the **SWSSG** a risk-based prioritisation of necessary resources required to effectively manage and control risks arising from the management of Water Systems to an acceptable level;
- Effectively manage and control identified risks arising from the Water Systems in the relative locations of the NHSGG&C Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this policy), and adherence to the NHSGG&C Water Systems Safety Policy at all levels within the relative locations of the Directorate of E&F;
- Ensuring that Estates & Facilities Staff, managed by the **DRP(W)**, through the Directorate management structure, are fully aware of their personal roles and responsibilities and appropriately trained in the statutory and mandatory requirements and standards for the management of safe Water Systems;
- Ensuring Water Systems are operated in accordance with the current guidance, and with the assessed risk of the individual systems under the control of the **DRP(W)**;
- Ensuring water system maintenance records are maintained and kept up-to-date;
- Regularly checking maintenance records;
- Ensuring all work is completed in accordance with the NHSGGC Operational Procedures.

A2.11 Acute Services Directors, HSCP Directors and Corporate Division Directors

NHSGGC Directors and Senior Managers, play an essential role in the safe management of Water Systems, actively ensuring and demonstrating that water safety is embedded within the culture of the organisation. **CRP(W)** will arrange awareness and responsibility training.

The responsibilities of Directors and Senior Managers include:

- Identifying and ensuring necessary formal records are maintained relating to Policies and Operational Procedures for Water Systems and raising any potential risks relating to Water Systems to the **RP(W)** and the **SWSSG**;
- Participate in training to maintain personal knowledge and a level of expertise allowing the efficient discharge of Director and Senior Manager responsibilities;
- Effectively manage and control identified risks arising from the Water Systems in the relative NHSGGC Premises areas of responsibility, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' and Operational Procedures related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGGC Water Systems Safety Policy at all levels within the relative NHSGGC Premises areas of responsibility;
- Ensuring that Staff, managed by the Director and Senior Manager are fully aware of their personal roles and responsibilities and appropriately trained in the statutory and mandatory requirements and standards for the management and operation of safe Water Systems;
- Facilitating Staff to allow their timely attendance at Water Safety training at the appropriate frequency, as per the NHSGGC Water Safety Policy and Operational Procedures which underpin this Policy;
- Ensuring Water Systems are operated in accordance with the current guidance, and NHSGGC Operational Procedures;
- Ensuring Water Systems records, including Staff training records, are monitored and kept up-to-date;
- Supporting the **DP(W)** and **DDP(W)** in the development of the Board's overall strategy in relation to the safe management and operation of NHSGGC Water Systems and for ensuring and demonstrating implementation within their areas of responsibility;
- Monitor and actively and effectively correct situations where inaction or actions by Staff put themselves and/or others at risk from actual or potential water safety incidents.

A2.12 Heads of Service (HoS), Departmental Managers (DMs), Clinical Managers (CMs) and Senior Charge Nurses (SCNs)

All managers and SCNs have a responsibility in the safe management of Water Systems, actively ensuring and demonstrating that water safety is sufficiently embedded in their departments, and for the safe, day to day management of facilities, Staff or services, and/or premises. **CRP(W)** will arrange awareness and responsibility training.

Water safety responsibilities that include:

- Familiarise themselves with the NHSGGC Water Safety Policy and local control measures including any water risk assessments for their area(s) of responsibility;
- Ensuring that persons in the department, clinic or ward are fully aware of their responsibilities and duties in respect of Water Safety, in particular, the action required of them should the area be defined as High Risk, listed in the site-specific Water Safety Written Scheme and Operational Procedures;
- Ensure that persons in the department, clinic or ward are fully aware of the 'Infrequently Used Outlets' definitions and Operating Procedure which underpins the NHSGGC Water Safety Policy;
- Actively promoting Water Safety within the department or ward by maintaining good housekeeping within the department or ward at all times, ensuring that any flushing or documentation as described in the Water Safety Written Scheme and Operational Procedures documentation is completed on time ;
- Responding appropriately to any water safety concerns of persons in the department, clinic or ward;
- Encouraging their staff and themselves to promptly report any breaches in the water system, such as water ingress, leaks etc. to estates;
- Nominating a responsible person to complete the Monthly 'Infrequently Used Outlets' Audit for each area, forwarding a copy to the Site Maintenance/Estates Manager, thereby assisting NHSGGC to consistently comply with its statutory and mandatory obligations;
- Ensuring that action is taken on a daily basis to address any access issues identified within the Cleaning Compliance Checklist Sign Off documentation retained in the Facilities Folder;
- Liaising with the Estates Department as required and in particular when outlets cannot be flushed e.g. broken so actions can be taken promptly.
- Ensure a flushing regime is place in accordance with specific duties under SHTM Guidelines (e.g. Clinical, Non-Clinical, Facilities, Domestics etc.)
Ensure part empty wards or areas, have an appropriate flushing regime in place in accordance with SHTM guidelines (e.g. Clinical, Non-Clinical, Facilities, Domestics etc.)

A2.13 Authorised Person's (Water) AP(W)P (Capital or Minor Works)

The **AP(W)P**, has the key role and will be specifically qualified, trained and experienced to allow the efficient discharge of their responsibilities. **AP(W)P** will be recommended by the **AE(W)** for appointment by the **CRP(W)**. This role can be outsourced for projects if resource internally is unavailable, however must still be signed of to work on projects.

The **AP(W)P** will also be responsible for establishing and formally appointing a sufficient number of Competent Persons (Water), **CP(W)**, to carry out various modifications to the Water Systems.

The **AP(W)P** will ensure all **CP(W)** managed by the **AP(W)P** are suitably trained, and formally engaged competent contractor(s).

The responsibilities of the **AP(W)P** include:

- Ensuring that delegated projects comply with all NHS GG&C policy and procedures.
- Identifying and ensuring the efficient formal record of relative Water System risks and raising those considered appropriate to the **DRP(W)P** for projects or **CRP(W)** for Minor Works;
- Provide formal reports to the **DRP(W)P** for Capital or **CRP(W)** for Minor works assuring the **DP(W)** and **DDP(W)** that the Board's statutory responsibilities relating to Water Systems, in relative locations, are being safely and appropriately discharged for projects;
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **AP(W)P** responsibilities;
- Identify to the **DRP(W)P** for Capital or **CRP(W)** for Minor works a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems within the scope of the project, to an acceptable level;
- Ensure during projects that risks are effective for the Water Systems in the relative locations of the NHSGGC Premises, to an acceptable level, as far as reasonably practicable during the project duration e.g. construction water safety plan;
- Ensuring during projects the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGGC Water Systems Safety Policy at all levels within the relative locations of the Directorate of Estates & Facilities;
- The **AP(W)P** will also be able to demonstrate:
 - o Successful completion of an appropriate professional course;
 - o A sufficient level of professional experience;
 - o Evidence of knowledge and skills relating to Water Systems;
- Participate in completion of :-
 - o **Form (025)** Design checklist for alterations to water systems ;
 - o **Form (029)** Record form for acceptance of work to be conducted and confirmation of work completed on a water system;

A2.14 Authorised Person's (Water) AP(W)

Including :-

Operational Estates – Estates Managers, Estates Supervisors etc.

The **AP(W)**, has the key operational role and will be specifically qualified, trained and experienced to allow the efficient discharge of their responsibilities. **AP(W)** will be recommended by the **AE(W)** for appointment by the **CRP(W)**.

Important elements of an **AP(W)** role are the comprehensive maintenance of formal records and the necessary quality of service and maintenance of systems to ensure their safety and integrity as detailed within the Written Scheme.

The **AP(W)** will also be responsible for establishing and formally appointing a sufficient number of Competent Persons (Water), **CP(W)**, to carry out maintenance and operational Procedures on Water Systems.

The **AP(W)** will ensure all **CP(W)** managed by the **AP(W)** are suitably trained, competent NHSGGC employees or formally engaged competent contractor(s).

Larger sites may require more than one **AP(W)**. Where more than one **AP(W)** is operating on a site, the **CRP(W)** will appoint one **AP(W)** to take a lead role **LAP(W)** ensuring effective, clear, unambiguous communications, with the purpose of safely discharging responsibilities and avoiding confusion and duplication.

The responsibilities of the **AP(W)** include:

- Identifying and ensuring the efficient formal record of relative Water System risks and raising those considered appropriate to the **RP(W)**;
- Provide formal reports to the **RP(W)** and **DRP(W)** assuring the **CRP(W)**, **DP(W)** and **DDP(W)** that the Board's statutory responsibilities relating to Water Systems, in relative locations, are being safely and appropriately discharged;
- Participate in a Compliance defined training programme for this role to maintain personal knowledge and a level of expertise allowing the efficient discharge of the **AP(W)** responsibilities;
- Identify to the **RP(W)**, **DRP(W)**, **CRP(W)**, **DP(W)** and **DDP(W)** a risk-based prioritisation of necessary resources required to effectively manage and control water system risks arising from the Water Systems to an acceptable level;
- Effectively manage and control identified risks arising from the Water Systems in the relative locations of the NHSGGC Premises, to an acceptable level, as far as reasonably practicable;
- Ensuring the implementation of all 'Statutory Instruments & Mandatory Guidance' related to Water Systems, (see examples in section, 'Guidance', in this Policy), and adherence to the NHSGGC Water Systems Safety Policy at all levels within the relative locations of the Directorate of Estates & Facilities;
 - Ensuring that estates staff, managed by the **AP(W)**, through the Directorate management structure, are fully aware and appropriately trained in the 'Statutory Instruments & Mandatory Guidance' and standards for the provision and maintenance of safe Water Systems;
- The **AP(W)** will also be able to demonstrate:
 - o Their application through familiarisation with the system(s) they are

- responsible for and the successful completion of an appropriate professional course;
 - o A sufficient level of professional experience;
 - o Evidence of knowledge and skills relating to Water Systems;
- Review and formally acceptance all installations, adoptions and modifications prior to implementation, engage with **RP(W)**, **RP(W)P** **DRP(W)P**, **DRP(W)** and/or **AE(W)** as required with respect to the scale, complexity and/or associated risks guidance.
- Participate in completion of :-
 - o **Form (025)** Design checklist for alterations to water systems ;
 - o **Form (029)** Record form for acceptance of work to be conducted and confirmation of work completed on a water system;

Appendix 3 – A3.0 Definitions and Acronyms

A3.1 Definitions

A3.1.1 Cleaning Compliance Checklist

A formal checklist of cleaning within the ward or department, signed off by the person in charge of the area confirming satisfaction of compliance with cleaning standards

A3.1.2 Control Measures

Considered, deliberate strategies, actions and activities employed, or stopped, which are designed to remove, reduce or mitigate risks that may diminish the ability to deliver safe and effective healthcare

A3.1.3 Domestic Cold Water

Cold potable water, either from water mains or storage systems, used by people for washing and drinking etc.

A3.1.4 Domestic Hot Water

Tempered Water for use by people for washing and bathing

A3.1.5 Engineering High Risk areas

The 'Engineering High Risk areas' are:

- In Water Systems treated with biocides, e.g. CLO2;
- Where water is stored;
- In water systems where the control levels of the treatment regime, e.g. temperature or disinfectant concentrations are not being consistently achieved or frequently vary from recommended levels;
- In water systems suspected or identified in a case or outbreak of Legionellosis where it is probable the Incident Control Team will require samples to be taken for analysis;
- In water systems suspected or identified in a case or outbreak linked to other potential water borne Pathogens where it is probable the Incident Control Team will require samples to be taken for analysis;
- In areas which have been identified within the current Water Safety Risk Assessment as being of a risk.

A3.1.6 Facilities Folder

A folder, held as documentary evidence and a formal record of procedures at ward / department level.

A3.1.7 Guidance / Mandatory Guidance

Guidance, policies, operational procedures/protocols and good industry practice etc. Guidance can be varied if the variation can be defended. Where Guidance is 'mandated' within general industry and in the NHS in Scotland, it becomes 'Mandatory Guidance' and may be referred to within Statutory Instruments as an 'Approved Code of Practice (ACOPs).

A3.1.8 High Risk Clinical Areas

- The ARHAI definition of High Risk (of infection) units are:
 - Haematology
 - Oncology
 - BMT

- Stem cell transplant units
- Neonatal Units
- Paediatric ICUs
- Adults ICUs
- Any other care areas where patients are severely immunocompromised through disease or treatments*(Renal, CF Units, ID).

A3.1.9 Infrequently Used Outlets

Water Systems' appliances that are used infrequently, as defined in 'Infrequently Used Outlets' definitions and Operating Procedure.

A3.1.10 NHSGGC Premises

All Hospitals, Health Centres, Clinics and other Properties, General Practice, Dental and other Surgeries, owned and or operated by NHSGGC where healthcare is delivered/provided to patients.

A3.1.11 Other Risk Systems

The following locations, systems and items of plant will have specific Control Measures applied to reduce the risk of infection.

- ultrasonic humidifiers/foggers
- spray humidifiers
- air washers, wet scrubbers, particle and trivial gas scrubbers
- water softeners
- emergency showers, eyebaths and face wash fountains
- sprinkler and hose reel systems
- spa pools
- whirlpool baths
- hydrotherapy pools
- birthing pool
- horticultural misting systems
- vehicle washers including automatic washers for cars, buses, lorries and railway rolling stock
- powered dental equipment
- fountains and decorative water features including those on display for sale
- non-disposable nebulisers used for respiratory therapy
- industrial effluent treatment plants
- irrigation systems
- fire, dust and odour suppression systems
- clinical wash-handbasins, drain outlets and connections
- wet drainage sump
- chilled beams
- cardiac heaters / coolers
- ECMO

A3.1.12 Incident Management Process SOP

The document [Incident Management Process Framework V1 - NHSGGC](#) provides a definition of an outbreak /incident and recommended actions. The actions include when to set up an incident meeting, who should be invited (including external expertise) and a sample agenda. It also provides guidance on communications within the HB, ARHAI and to the Scottish Government.

A3.1.13 Pathogens

Microorganisms that are, or may become, harmful to people.

A3.1.14 Risk Reduction Strategies

Risk Reduction strategies/procedures can include, but are not limited to:

- Policy awareness and implementation;
- Risk assessment both generic and specific;
- Training, e.g. WH001 Legionella Management HTM 04-01 and WH003 Legionella Control within Hot and Cold Water Systems used in NHSGGC for **APs(W)**, **DRP(W)**, **RP(W)** etc.;
- The development, approval and implementation of local procedures;
- Reporting and recording;
- Evaluating effectiveness of risk reduction strategies/procedures;
- Reviewing in the light of experience, e.g. looking at incident investigations and inspection reports. Do they show improvement?;
- Re-train Staff if required, reading available policies, strategies and procedures;
- Review clinical and workplace risk assessments after reports of any adverse events;
- Implementation of risk reduction strategies as defined by the findings of the risk assessment for the NHSGGC buildings;
- Implementation of a formal review and/or audit process of the risk reduction procedures;
- Implementation of contractor audit and review procedures;
- Review and update Written Scheme and water action plan every 2 years or following material system amendments/change of use.

A3.1.15 Sector

A designated area of NHSGGC that is a recognised Sector of NHSGGC Premises.

A3.1.16 Staff

People employed by NHSGGC on various contracts and will include locum, bank, volunteers etc.

A3.1.17 Statutory Instruments

Laws, regulations etc. that have legal standing and are applied by enforcing authorities.

A3.1.18 Water Systems

All domestic hot and cold water systems, water-dispensing equipment as well as defined, 'at risk' water-carrying systems across all NHSGGC premises.

A3.1.19 Water Dispensing Equipment

Equipment or machinery dispensing water, in all forms and states, for consumption and or use by people, e.g. Water coolers, Ice-making machines etc.

A3.1.20 Written Scheme & Operational Procedures

A document written to record and communicate, in detail, how responsibilities relating to the safe operation and management of Water Systems will be discharged and will describe who will have responsibilities for their safe and effective implementation

A3.2 Acronyms

ACoP	Approved Code of Practice
AE(W)	Authorising engineer (Water)
AP(W)	Authorised Person (Water)

1.0 GENERAL OVERVIEW

Note 1: No work will be carried out on the water system without the knowledge and written consent of the Authorised Person (Water).

Note 2: This Written Scheme document is to be read in conjunction with the Operational Procedures for the Written Schemes document and should also be read in conjunction with the Control of Water Records document. For any alterations to the Water System this Written Scheme Document is to be read in conjunction with the Guidance for alterations to water systems document.

1.1 Introduction

This document contains six sections which have been derived from the Risk Assessment to aid the design, installation, maintenance and operational mode of all domestic and process water systems within the premises with respect to the likelihood of the proliferation of waterborne micro-organisms. The assessment also considered the risk of infection presented to building users and the general populous at large, and derived a series of risk ratings and appropriate Remedial Actions and Control Measures, which should be implemented to minimise the presented risks. This Risk Assessment was carried out in a manner consistent with the requirements of *BS8580:2010 Water Quality – Risk Assessments for Legionella Control – Code of Practice*, and is reviewed whenever system alterations or operational considerations may effect a change in the risk.

Section 1 contains an Executive Summary of the recommended control measures and corrective actions together with an overview of the QUEH Site layout and accommodation.

Section 2 contains a record of the logbook inspection, details on the location of records, defects, non-compliance issues, correspondence and archived information.

Section 3 provides information on the management structure associated with the control scheme for the water system and clear definitions of responsibilities held by those named, details of training undertaken and a summary of the designated tasks as detailed in section 4.

This section also provides information on the details of the risk assessment values associated with representative outlets, systems and plant items undertaken since 2013. A generic risk assessment for any positive legionella test results within designated Low Risk locations and a description of the installed plant and equipment with associated schematic layout plans for each of the installed water systems within the site is also contained within this section.

Section 4 of the document details the safe operation of the system and all appropriate Maintenance Procedures (Control Measures) which were derived from the Risk Assessment and recommendations within NHS Greater Glasgow and Clyde Water Systems Safety Policy.

This section of the document contains a task description with associated record (Log) sheet relating to these activities. It should be noted however, that in certain circumstances, specialist contractors are required to implement some Control Measures, and records pertaining to these activities may be held under separate cover. Such activities would typically include those associated with chemical water treatment regimes and drinks vending machines sanitising maintenance.

Refer to Section 2 for the location of records and archived information associated with the maintenance procedures and other control measures.

Section 5 contains supporting information relating to the Control Scheme, and should typically include the recording of system alterations or remedial actions together with utilised materials. Ad hoc maintenance activities should also be recorded in this section, such as system sterilisations which may be required from time to time. This section of the document also contains a glossary of supporting publications, where additional information relating to the risks associated with waterborne micro-organisms, and water quality generally, may be found.

1.2 Executive Summary

The purpose of this Written Scheme document is to assist in the correct and safe operation of the water systems within the QEUH Campus. The document outlines the specific roles, responsibilities, training requirements and regular maintenance procedures to be followed in order to ensure compliance with statutory and mandatory guidance.

Risk Assessments for the water services have been carried out on the instruction of the Board Water Safety Group. DMA Canyon Ltd are presently the appointed Water Systems Risk Assessor and have carried out Risk Assessments within all individual buildings on the campus.

Additionally there are two Hydrotherapy Pools in operation on the campus. These are situated within the New Childrens Hospital, and Spinal Injuries Unit. Separate Risk Assessments have been carried out for both of these facilities by a specialist Swimming Pool Risk Assessment provider.

Risk Assessments require to be reviewed and updated to reflect any changes in-use and / or functions that have taken place since the date of the original Risk Assessment or in the event of control measures becoming ineffective, changes in key personnel or in the event of a case of legionnaires disease / legionellosis associated with the water system. Guidance on the Risk Assessment review procedure is given in Appendix 3.

All documentation and log sheets used to record maintenance activities follow the format contained within guidance document SHTM 04-01 Part G: *Operational Procedures and Exemplar Written Scheme*.

1.3 Overview of Site Accommodation and Premises

The main new-build Adult Hospital building comprises of 12 stories, with the basement housing FM areas and the new-build Childrens Hospital comprising of 4 stories.

On the retained estate there are individual buildings comprising of Neurology, Neurosurgery, Spinal Injuries Unit, PDRU, Maternity, Neo-Natal, Podiatry and Westmarc stand alone with the Teaching and learning and office block new additions.

Full descriptions and information on the individual written schemes are available in the Log book/Risk Assessment folders for each building.

The building codes are as follows:

AC – Minor Injuries Unit
 AQ – Acute Medical Block (AMB)
 AS – Central Medical Block (CMB)
 BC – Neurosurgical Block (INS)
 BL – Maternity
 BW – Neurology
 DA – Spinal Injuries
 DB – Maternity Day Surgery
 DD – Podiatry
 DE – Physically Disabled Rehabilitation Unit (PDRU)
 DI – WestMARC
 EA – Neo Natal
 FA – Multi Storey Car Park 2
 FB – Multi Storey Car Park 1
 GA – Laboratory Medicine
 GB – Energy Centre
 HA – Adults Hospital
 HB – Childrens Hospital
 IA – Teaching & Learning Centre
 IB – Office Building
 IC – Imaging Centre of Excellence (ICE)

NOTE: ICE building is owned by University of Glasgow (UoG). Facilities management and maintenance is carried out under contract by NHS GG&C on behalf of UoG.

Langland Building is managed via PFI by Serco and MDU is managed via Vanguard.

See Site Map in Appendix 1

2.0 RECORDING

2.1 Written Scheme Inspection Records

Anyone inspecting this written scheme (either as part of the Management Control System or otherwise) is invited to make an entry in this inspection record. **Under no circumstances may this Written Scheme or any part of it be removed from site.**

Date/Time	Comments	Signature	Position
June 2018	Written scheme has been reviewed and re-formatted into this current form (Revision D) by Colin Purdon as part of the water systems review.		Site Manager Operational Estates
Feb 2019	Written scheme has been reviewed and re-formatted into this current form (Revision E) by Colin Purdon as part of the water systems review.		Interim Sector Estates Manager (Deputy Responsible Person)
May 2019 Rev B	Written scheme has been reviewed and re-formatted into this current form (2019 Rev A) by Colin Purdon as part of the water systems review.		Interim Sector Estates Manager (Deputy Responsible Person)
October 2020 Rev C	Written scheme has been reviewed to reflect changes to staff personnel and a review of procedures.		Site Manager Operational Estates
May 2021 Rev D	Written scheme has been reviewed to reflect changes to staff personnel and a review of procedures.		Site Manager Operational Estates
Aug 2022 Rev E	Written scheme has been reviewed to reflect changes to staff personnel and job titles. Additionally modified procedures for WS01 (Page 103)		Site Manager Operational Estates
Jan 2023 Rev F	Minor changes to words regarding daily flushing		Site Manager Operational Estates
May 2023 Rev G	Index section 2 missing now added back in		Site Manager Operational Estates
Oct 2023 Rev H	Inclusion of Vanguard who carry out maintenance of the MIU Unit and minor changes to wording. Also added fixed shower head disinfections. Changed Appendix 2 to reference WQS014		Site Manager Operational Estates

Additional entries should be completed on a separate sheet and inserted in Section 2.1 with this sheet.

Details of any correspondence, including Risk Assessments/Reviews and Ongoing Monitoring Reports, relating to water services should be entered on the sheet below, recording where held and by whom.

[illegible]

Version 2023 Rev H
A48946859

2.3 Non-Compliance Issues and Fault Detail Log

Record Form 004

All non-compliance and fault details in relation to the individual systems in each building must be recorded on Record Form 004 and brought to the attention of the Water Systems Lead AP as soon as possible. This process ensures that all non-compliance issues are documented, managed effectively and tracked through to completion and close –out of the issue. Copies of Record Form 004 are to be stored within the shared drive. SCART Compliance/22 Water/.

The process for sampling out of specification is documented in WQS – 017 Procedures in the event of out of specification sample for Legionella and other monitored bacteria, moulds etc.

2.4 Archived Information Record Sheet

All records associated with the management or maintenance procedures within this Written Scheme should be kept for a period of five years after they are no longer current. Records should be kept locally within the main Estates Office. The details of any archived information held separately in secure storage should be recorded in the table below.

Date	Procedure or Record Reference	Description	Held By/Location

Additional entries should be completed on a separate sheet and inserted in Section 2.4

2.5 Equipment Calibration Records

All equipment used for the measurement of temperatures should be calibrated at least annually to ensure the accuracy and consistency of the recording procedures.

Calibration certificates for handheld thermometers are held in hard copy within the QEUH Campus Log Book suite in the main estates office. Electronic copies are also held on the QEUH Shared Drive>Water Quality folder.

3.0 MANAGEMENT ARRANGEMENTS

3.1 Roles & Responsibilities

NHS Greater Glasgow & Clyde Chief Executive – (Duty Holder)	The Chief Executive has ultimate responsibility / accountability for water system safety within NHSGG&C. The responsibilities of the Chief Executive include: • Responsibility for implementation of the relevant mandatory and statutory elements contained within the Health & Safety Commissions Approved Code of Practice and Guidance “Legionnaires Disease. The control of Legionella bacteria in water systems” L8 (ACOP L8), SHTM04-01: The control of Legionella, hygiene safe” hot water, cold water and drinking water systems and CEL 08(2013) water sources and potential risk to patients in high risk units – revised guidance. The implementation of Guidance for neonatal units (NNU’s) (levels 1, 2 & 3) adult and paediatric intensive care units ICU’s in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water. • Ensuring that adequate resources are provided to meet the Water Systems Safety requirements of NHSGG&C estate. Ensuring that the Water Systems Safety Policy is being implemented at all levels. • Reviewing and monitoring the operation of the Water Systems Safety Policy through the Board Corporate Management Team and ensuring that clear guidelines are provided for this tasked with compliance of legislative and statutory standards. • Appointing the Designated person (Pseudomonas) and Designated Person (Water) to assist in the execution of these responsibilities, who for NHSGG&C are the Infection Control Manager (Pseudomonas) and the Director of Facilities (Water).
NHS Greater Glasgow & Clyde Director of Estates and Facilities – (Duty Holder)	The Director of Estates and Facilities is the Designated Person (Water). They shall be responsible for: • Ensuring that Estates and Facilities staff, through the general management structure is fully aware of the current statutory and mandatory requirements and standards for the provision and maintenance of safe water systems. • Ensuring with the Responsible Person (Pseudomonas) that the Water System Safety Policy is regularly reviewed and updated. • Co-Chair the NHSGG&C Water Systems Safety Group. • Appointing in writing the Responsible Person (Water) at sector level and Deputy Responsible Person(s) (Water) at site level. This shall be the Sector Estates Manager (SEM) and the relevant Site Manager Operational Estates (SMOE)/Site Estates Manager within the Facilities Directorate management structure.

3.1 Roles and Responsibilities (cont)

NHS Greater Glasgow & Clyde Director of Estates and Facilities – (Assistant Duty Holder)	The Assistant Director of Estates and Facilities is the Assistant Designated Person (Water). They shall be responsible for assisting in : • Ensuring that Estates and Facilities staff, through the general management structure is fully aware of the current statutory and mandatory requirements and standards for the provision and maintenance of safe water systems. • Ensuring with the Responsible Person (Pseudomonas) that the Water System Safety Policy is regularly reviewed and updated. • Co-Chair the NHSGG&C Water Systems Safety Group. • Appointing in writing the Responsible Person (Water) at sector level and Deputy Responsible Person(s) (Water) at site level. This shall be the Sector Estates Manager (SEM) and the relevant Site Manager Operational Estates (SMOE)/Site Estates Manager within the Facilities Directorate management structure.
NHS Greater Glasgow and Clyde Infection Control Manager - Designated Person (Pseudomonas)	The Infection Control Manager supported by the Board Infection Control Doctor is the Responsible Person (Pseudomonas). They shall be responsible for: • Ensuring that Infection Control Teams are fully aware of current guidance on Legionella control matters and the minimisation of the risk of Pseudomonas aeruginosa infection from water. • The implementation of Guidance for neonatal units (NNU's) (levels 1, 2 & 3) adult and paediatric intensive care units ICU's in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water. • Ensuring with the Designated Person (Water) that the Water System Safety Policy is regularly reviewed and updated. • Co-Chair the NHSGG&C Water Systems Safety Group. • Appointing in writing the Responsible Person(s) (Pseudomonas) at sector level. This shall be the relevant Infection Control Doctor.
Assistant Head of Estates - Responsible Person (Water)	The Assistant Head of Estates will be appointed as the Responsible Person (Water) at Sector level by the Director of Estates and Facilities in writing. The Sector Estates Manager is responsible for: • Ensuring the effective maintenance of engineering controls installed for the purposes of controlling water systems. • Ensuring that written schemes and risk assessments are in place and reviewed regularly. • Devising and maintaining procedures to ensure the quality of water on premises is maintained. • Ensuring operational procedures are carried out and documented. • Ensuring records are kept of all water systems and their purpose, giving locations recording and maintaining within the Boards estates management system. • Liaise closely with other professionals to ensure legislative and statutory compliance is maintained by the Board.

3.1 Roles and Responsibilities (cont)

3.1 Roles and Responsibilities (cont) Authorising Engineer (AE)	An Authorising Engineer acts as an independent professional advisor to the healthcare organisation, appointed by the organisation with a brief to provide services in accordance with Scottish Health Technical Memorandum (SHTM) guidance. He will be appointed in writing by the Director of Facilities/General manager (Estates). The Authorising Engineer acts as an assessor, making recommendations for the appointment of Authorised Persons, monitoring the performance of the service and providing an annual audit to the organisation's Designated Person.
Authorised Person (Water)	The Authorised Person (water) has the key operational responsibility for the service, qualified, sufficiently experienced and skilled for the purpose. They will be nominated by the Authorising Engineer and be able to demonstrate • They application through familiarization with the system and attendance at an appropriate professional course; • A level of experience; • Evidence of knowledge and skills. An important element of the Authorised Person (Water) role is the maintenance of records, quality of service and maintenance of system safety (integrity). The Authorised Person (Water) will also be responsible for establishing and maintaining the roles and validation of Competent Persons (Water) who shall be suitable trained employees of the organisation or appointed contractors. Larger sites may require more than one Authorised Person (Water) for a particular service. The Authorised Person (Water) will be appointed by the General Manager – Capital Planning.

3.1 Roles and Responsibilities (cont)

Head of Capital Planning (Water)	The Head of Capital Planning will be appointed as the Deputy Responsible Person (Water) at Board level by the Director of Estates and Facilities in writing. The General Manager for Capital Planning is responsible for: • Ensuring that any new works undertaken or refurbishment within existing premises shall comply with the requirements of this Policy and the Written Scheme and Operational Procedure for managing Water Safety including The control of <i>Legionella</i>, hygiene, 'safe' hot water, cold water and drinking Water systems and The implementation of Guidance for neonatal units (NNU's) (levels 1, 2 & 3) adult and paediatric intensive care units ICU's in Scotland to minimise the risk of <i>Pseudomonas aeruginosa</i> infection from water. • Ensuring that all potential interfaces between an operating system and new and refurbishment works shall meet the approval of the Responsible Person (Water) and Authorised Person (water) as to methodology for making that interface. • Ensuring that any work involving the installation of water services or equipment requiring a water supply shall follow the guidance in SHTM 04-01 and HSE document L8 and shall be certified by the design Engineer as to that compliance. • Ensuring that any works which will affect an operational water service will be discussed with the Estates Authorised Person (Water) prior to arranging that work.
Site Estates Manager Deputy Responsible Person (Water)	The Site Manager Operational Estates (SOME) shall be appointed in writing by the Director of Facilities/General Manager (Estates) in writing as the Deputy Responsible Person (Water) and will also act as the Designated Person Water in the absence of the Designated Person (Water). The Site Maintenance Manager/Site Estates Manager is responsible for: • Ensuring all staff conducting water system maintenance are competent to do so. • Ensuring water system maintenance records are maintained and kept up-to-date. • Regularly checking maintenance records. • Ensuring all work is completed in accordance with the NHS GG&C Estates Procedures.

3.1 Roles and Responsibilities (cont)

Acute Services Directors CH(C)P Directors and Corporate Division Directors	As Senior Managers, NHSGG&C Directors play an intrinsic role in ensuring that water safety is embedded within the culture of the organisation. The responsibilities of Directors include: - Supporting the designated person (Water) and (Pseudomonas) in the development of the Board's overall strategy in relation to water safety and for ensuring implementation within their areas of responsibility; - Ensuring that all staff are made aware of their requirement to attend Water Safety training at the appropriate frequency, as per the NHSGG&C Water Safety Policy and Operational Procedures which underpin this by facilitating staff release from duties to attend training; - Supporting action to address staff who put themselves and/or others at risk from a real or potential water safety incident.
Heads of Service, Departmental Managers, Clinical Managers, Senior Charge Nurse's	All managers who have a responsibility for the day to day management of facilities, staff or services, and/or premises, have water safety responsibilities that include: - Familiarise themselves with the NHSGG&C Water Safety Policy and local control measures including any water risk assessments for their area(s) of responsibility; - Ensuring that persons in the department, clinic or ward are fully aware of their responsibilities and duties in respect of Water Safety, in particular, the action required of them should the area be defined as High Risk by the local Water Safety Group - Ensure that persons in the department, clinic or ward are fully aware of the Infrequently Used Outlets definitions and Operating Procedure which underpins the NHSGG&C Water Safety Policy
Heads of Service, Departmental Managers, Clinical Managers, Senior Charge Nurse's (cont)	- Actively promoting Water Safety within the department or ward by maintaining good housekeeping within the department or ward at all times, ensuring that any flushing or documentation as described in the Water Safety Written Scheme and Operational Procedures documentation is completed on time - Responding appropriately to any water safety concerns that persons in the department, clinic or ward have; - Nominating a responsible person to complete the Monthly Infrequently Used Outlets Audit for each area, forwarding a copy to the Site Maintenance Manager, thereby assisting NHSGG&C to meet its statutory and mandatory requirements; - Ensuring that action is taken on a daily basis to address any access issues identified within the Cleaning Compliance Checklist Sign Off documentation retained in the Facilities Folder. - Liaising with the estates department as required

3.1 Roles and Responsibilities (cont)

Legionella Risk Assessor	The NHS Board appoints in writing a Legionella Risk Assessor with terms of reference to provide services in accordance with BS 8580, SHTM 04-01 and HSE guidance under this Policy. He/she will be appointed in writing by the Director of Facilities/General Manager (Estates)
Competent Person (Water)	The Competent Person (Water) provides skilled installation and/or maintenance of the specialist service. He/she will be appointed, or authorised to work (if a contractor) by the Authorised Person Water). He/she will demonstrate a sound trade background and specific skill in the specialist service, working under the direction of the Authorised Person (Water) in accordance with operating procedures, policies and standards of the service.
Maintenance Tradesperson	A Maintenance Tradesperson is someone who has sufficient technical knowledge and the experience necessary to carry out maintenance and routine testing of the water supply, storage and distribution system.
Installer	The Installer is the person or organisation responsible for the provision of the water storage and distribution system.
Contractor	A Contractor is the person or organisation designated by management to be responsible for the supply, installation, validation and verification of hot and cold water services, and for the conduct of the installation checks and tests in relation to the control of <i>Legionella</i>. The NHS Board will expect potential contractors to have suitable qualifications (for example companies/individuals who are members of the <i>Legionella</i> Control Association).

3.1 Roles and Responsibilities (cont)

NHS GG&C South Sector (QEUH) Hierarchy Appointment Table

Designation	Position	Name Tel Number
The Duty Holder	Chief Executive	Jane Grant
Designated Person (Water)	Director of Facilities/General Manager (Estates)	Tom Steele
	Assistant Director (Estates)	Mark Riddell.
Authorising Engineer (Water)	AE	Dennis Kelly [REDACTED]
Legionella Risk Assessor	DMA Water Services Ltd	David Watson Mike Kinghorn [REDACTED]
Responsible Person (Water)	Sector Estates Manger (South)	Euan Smith
Deputy Responsible Person (Water)	Site Manager Operational Estates (Building)	Kerr Clarkson
Deputy Responsible Person (Water)	Head of Capital Planning	James Huddleston
Lead Authorised Person	Estates Manager	Mel MacMillan
Authorised Persons	Estates Manager Co-ordinating Supervisor Co-ordinating Supervisor Co-ordinating Supervisor	Darren Hopkins Grant Bennet William Fenn Daniel Martin
Competent Persons	CAD Technician	Mark McGowan
Competent Persons	Plumbers/Engineers	See training records in Section 3.4
Others Involved		
Microbiology	Consultant Microbiologist	Alistair Leonard Linda Bagnade Aleksandra Marek
Infection Control	Director Lead Nurse Lead Nurse	Sandra Devine Gillian Bowskill Lynn Pritchard
Public Health		Dr Iain Kennedy
Laboratory Services		Sandra Higgins

3.2 QEUH Estates Staffing

Management organogram for QEUH Estates Dept as of Oct 2019

3.3 Required Maintenance Tasks

The maintenance and management of the water systems throughout the QEUH Campus is undertaken by a combination of both NHS Staff and external Contractors at the frequencies identified in the following tables.

QEUH Management staff manage and oversee the following tasks:

Procedure Reference	Operation(s)	Record Form Ref	Frequency
P1C1	BMS Temperature Monitoring (Carried out by NHS Estates)	Requires new number	Daily
P1CC1A	Manual Temperature Monitoring for calorifiers (different form used ONLY REQUIRED if no BMS Monitoring)	(005a)	Daily
N/A	Filtration Plant Checks (Carried out by NHS Estates)	028c	Twice Daily
WS01	Daily flushing of all outlets (Carried out by NHS Facilities)	-	Daily
WS01	Deluge shower/Eye wash flushing (1 off carried out by NHS Estates and 1 off by DMA)	(026)	Twice Weekly
WS01	Flushing of little used outlets * frequency based on risk (Carried out by NHS Clinical) see page 103	-	Daily or Twice weekly
P1C3	Pump operation/duty rotation (Carried out by NHS Estates)	(028a)	Weekly
P1C4	Temperature Recording of Sentinel Hot and Cold Water Outlets. (Carried out by NHS Estates)	(005c)	Monthly
P1C4	DHW Calorifier and Buffer Vessel Checks (Carried out by NHS Estates)	(005)	Monthly
P1C6	DWS Calorifier, Expansion Vessel Flushing (Carried out by NHS Estates)	(006) (023)	Monthly
P1C12	Showerhead/hose replacement/disinfection (<i>No longer carried out as shower head and hoses replaced quarterly</i>)	(005b)	Quarterly
WS01	Review of Rarely Used Water Outlets and Changes In-Use (As required by NHS Estates)		Quarterly
P1C9	DWS Calorifier / Expansion Vessel Inspection (Carried out by NHS Estates)	(006)	Annually
N/A	Water Services Pipework and Distribution System Checks (Carried out by NHS Estates during calorifier checks, Plant Room checks and by DMA during Tank Room checks)		Annually
N/A	Vibration coupling inspection (Carried out as part of checks on booster pumps) (Carried out by NHS Estates)		Annually
N/A	Carry out review of log books and Written Scheme		Annually (Sep)
N/A	Carry out review of drawings and schematics		Annually (Sep)

3.3 Required Maintenance Tasks (cont)

In addition to the tasks undertaken by NHS directly employed Competent Persons, there are also tasks undertaken by Contractors on a selection of buildings within the campus.

Appointed Service Providers presently undertake the following tasks:

Procedure Reference	Operation(s)	Record Form Ref	Frequency
WS01	Deluge shower/Eye wash flushing (Carried out by DMA)	DMA Records	Twice Weekly
WS01	Flushing Deadlegs and drain valves (Carried out by DMA)	DMA Records	Twice Weekly
WS01	Flushing Intermittently used outlets (Carried out by DMA)	DMA Records	Twice Weekly
	External Water Mains Valve Operation and Flushing Routines		Monthly
PIC4	Temperature and CL02 monitoring of outlets (Carried out by DMA)	DMA Records	Monthly
-	PPM Schedule Monthly Visually inspect chemical delivery system, Check chemical suction and delivery lines for correct operation Chemical level check and refill , Cross check measured ClO ₂ / Chlorite residual test against analyser & Palintest Kit, Check and Adjust controller settings as required (Carried out by ScotMas)	ScotMas Records	Monthly
	PAL Filters on taps outlets (Carried out by DMA)	DMA Records	
	'TMV' and Mixing Valve Sanitation and Maintenance Checks (Carried out by DMA)	Carried out 6 monthly	Quarterly
N/A	TMV/TMT & Thermostatic Shower Disinfection and Function Test (HIGH RISK) (Carried out 6 monthly)		Quarterly
	Shower Head and Flexible Hose Exchange (Carried out by DMA)	DMA Records	Quarterly
	Shower Head and Flexible Hose maintenance e.g. fixed shower heads, bath, eye wash heads etc (Carried out by WATER SERVICE PROVIDER)	DMA Records	Quarterly
WQS 001	HORNE Tap Flow Restrictor Exchange (Carried out by DMA)	DMA Records	Quarterly
	'TMV/TMT' Tap Outlet Sanitisation and Operational Checks (Carried out by DMA)	DMA Records	Six-Monthly
N/A	TMV/TMT & Thermostatic Shower Disinfection and Function Test (Non-HIGH RISK) (Carried out by DMA)	DMA Records	Six-Monthly
-	Maintenance of filtration units (Carried out by Veolia)	Veolia Records	Six-Monthly
-	6 Monthly Visit– All above, plus, Check ClO ₂ gas detector functionality and recording levels, Simulate fault circuitry and alarm on Sentinel Monitor, Change probe electrolyte and cross calibration test, Carry out manual Chlorate & Chlorite validation tests (12 representative outlets), Check water meter operation and report o Electrolyte top up, Probe calibrations (Carried out by Scotmas)	ScotMas Records	Six-Monthly
PIC7	CWST Inspection and Temperature Monitoring (Carried out by DMA)	DMA Records	Six-Monthly

3.3 Required Maintenance Tasks (cont)

	'TMV' Tap Outlet Sanitisation and Operational Checks (Carried out by Vanguard - MIU)	Vanguard Records	<i>Annual</i>
	CWST Inspection (Carried out by DMA)	DMA Records	<i>Annually</i>
	Hot and Cold Tap Outlet Sanitisation and Operational Checks (NOT CARRIED OUT UNLESS ISSUE IDENTIFIED THROUGH SAMPLING)	DMA Records	<i>Annually</i>
-	As per 6 monthly and ClO2 & Chlorite Probe membrane cap replacement, Dosing Pump diaphragm valve replacements, Replace ClO2 gas detector cartridge if required (Carried out by Scotmas)	ScotMas Records	<i>Annually</i>
P1C10	Representative Tap Temperature Monitoring Note all tap temperatures are checked through TMT/TMV maintenance (Carried out by DMA)	DMA Records	<i>Annually</i>
	BMS Sensors (Carried out by Schneider and MCE BMS Providers for respective BMS)	Schneider & MCE records	<i>Annually</i>

3.4 Training Records

The following NHS personnel are certified to have the required ability, experience, instruction, information and training to carry out the work associated with legionella precautions at QEUH Campus.

NAME	POSITION	NATURE OF TRAINING (QUALIFICATION, TRAINING COURSES ATTENDED)	DATE
Euan Smith	Sector Estates Manager RP	Responsible Person Course ENAP City & Guilds Authorised Person ENWS City & Guilds Managing Water Systems	
Kerr Clarkson	Site Manager Operational	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	
Mel MacMillan	Estates Manager Lead AP	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	
Daniel Martin William Fenn	Trainee Estates Managers AP	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	
Grant Bennet Darren Hopkins	Co-Ordinating Supervisor AP	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	

Copies of all relevant training records and appointment letters are held electronically on the QEUH Shared Drive within the folder path “Water Quality>Training and Appointments”.

The results achieved by each member of staff during their competency training are held on the central database managed by the Water Systems Compliance Manager.

NAME	POSITION	NATURE OF TRAINING (QUALIFICATION, TRAINING COURSES ATTENDED)	DATE
Martin Inglis	Tech Plumber	Competent Persons	
Andrew Hamilton	Tech Plumber	Competent Persons	
David Fickling	Tech Plumber	Competent Persons	
Mark McNally	Tech Plumber	Competent Persons	
Shawn O'Neill	Tech Plumber	Competent Persons	
Jason Weir	Tech Plumber	Competent Persons	
Adam Gardner	Tech Plumber	TBC	
Robert Grant	Tech Plumber	TBC	
Ryan Ogilvie	Tech Plumber	TBC	
Gavin Goodall	Apprentice	TBC	
Paul Kelly	Apprentice	TBC	
Mark McGowan	CAD Technician	TBC	

Copies of all relevant training records and appointment letters are held electronically on the QEUH Shared Drive within the folder path “Water Quality>Training and Appointments”.

The results achieved by each member of staff during their competency training are held on the central database managed by the Water Systems Compliance Manager.

3.5 Training Requirements

A programme of training and procedures to assist in assessing and ensuring the competence of ALL persons responsible for the operation, maintenance, repair and alteration to the water distribution system and associated plant and equipment requires to be progressed, developed and implemented.

QEUH Estates Staff - Interim Training Requirements:

Item	Training Requirement	Applicable to	Target Date for Completion	Date Completed
1	Toolbox talks on Written Scheme Section 4 for staff.	All plumbers		
2				
3				
4				
5				
6				
7				
8				
9				
10				
11				
12				

NOTE:- This table should be updated on a regular basis as part of the review process described in **Section 3.10.**

3.6 Water Systems Risk Assessment

The duly appointed *Legionella* Risk Assessor for *Legionella* and Water Systems Safety will update the *Legionella* risk assessment database as directed by the board.

Risk assessments for each building have been conducted by DMA Water Ltd and are filed in the main Estates Office at QEUEH. Each contains details of individual systems and a summary of the associated risks. The risk assessments each contain unique information in regard to the water distribution systems in the buildings and also guidance on the recommended maintenance procedures for mitigating risk.

Risk Assessment Review-Escalations

During the Risk Assessment, whenever an anomaly is discovered on either the hot or cold water systems, the Risk Assessors e-mail the AP (water) with their findings. These anomalies are actioned by creating a FM job for the onsite CP Plumbing Technician. The findings are held in the Estates office in the folder named (Pre Risk Assessment Jobs completed).

Risk Assessment Process for Removal of Identified Items

Points are actioned that have been identified in the Risk Assessment, all drawings are updated to reflect the changes and the Risk Assessment action point is closed.

Risk Assessment Review Schedule

A review of the Risk Assessments MUST be carried out after or during the following:

A change to the water system or its use

A change to the use of the building/ward/clinic/dept etc.

Changes in legislation or updates in control measures

Changes in immediate management or key personnel

Control measures becoming ineffective

Increased micro-bacterial levels found in the water system or a case of legionnaires disease/legionellosis associated with the water system.

Action plan details for each risk assessment are summarised on the Smartsheet tool.

Electronic copies of the Risk Assessments are also held on the QEUEH Shared Drive at the folder path

“Water Quality>Risk Assessments”

Further information on reviewing Risk Assessments is detailed in Appendix 3.

3.7 Plant Description and Schematics

Details of the plant in each building and schematic layouts are contained within the individual log books/risk assessments for each building. The log books/risk assessments are stored in the main Estates Office at QEUH.

These details are also held on the Shared Drive

All plant details and system schematics and as-fitted drawings for the Adult & Childrens Hospitals are contained in the ZUTEC cloud based document management system. All Estates Managers and Supervisors have access to these systems.

Additional access accounts can be set up at the request of the QEUH Site Manager Operational Estates.

[Brendan.egan](#) [REDACTED]

3.8 Water Systems Audits/Review Procedures

A duly appointed Authorising Engineer (Water) will audit the entire Water Safety procedures within *NHS Board* annually.

The appointed Authorising Engineer for Water Safety will produce an annual report for management review. *See Section 3.1 pg 18 for current appointments.*

AE Audit

The Lead Authorised Person (Water) must regularly gather and maintain all the relevant information and records, including relevant Water Safety Risk Assessments and Written Schemes.

Working with the Authorising Engineer (Water) and Responsible Person (Water), the relevant Authorised Person (Water) will review and analyse all records for compliance with *Legionella* and other water safety parameters.

The relevant Authorised Person (Water) will detail on these records any deviations from the *Legionella* and other water safety parameters giving a brief description as to the reason for this deviation.

The Audit Programme will consist of planned audits on the following elements, for example:

Risk Assessments;

All documentation associated with this Written Scheme

training review and records;

schematic drawings;

Water Safety Log Books/Maintenance records;

BMS trend log comparison.

A report will be produced summarising the audit for submission to the Sector Water Safety Group.

The Lead Authorised Person (Water) will file locally, all relevant information and maintain hard copy records in the Water Safety Log Books stored within the main Estates Office. All actions identified should be tracked to ensure completion and closure.

Summary of Internal/External Audit Procedures

Frequency	Task	By Whom
Annually	Carry out Authorising Engineers Audit and produce report for submission to Sector Water Safety Group (Section 3.8 WS)	Lead AP, AE,
Annually/May	Carry out annual review of written scheme and produce report for submission to Sector Water Safety Group (Section 3.9 WS)	RP/DRP, Lead AP, Compliance Mgr
6 monthly	Carry out management review (Section 3.10 WS)	RP/DRP, Lead AP, Compliance Mgr
Monthly	Carry out regular audit of SCART topic and update database (Section 3.11 WS)	Lead AP
Monthly	Conduct contractor meetings/audits to ensure compliance with legislation and training requirements.(Section 3.12 WS)	Lead AP

3.9 Written Scheme Audit Procedure

The Written Scheme will be audited at agreed intervals but should be at least annually.

An audit schedule will be prepared to ensure the entire procedure is audited. This should be done in conjunction with the Lead AP (Water Systems), Compliance manager, and Responsible Person (Water Systems). A report should be produced and submitted to the Sector Water Safety Group.

3.10 Management Review

The Responsible Person (Water) will hold regular review meetings to confirm current compliance with Water Safety System requirements, identification of any deficiencies and actions required to resolve staff training needs.

The management review will be based on following:

- Results of internal audits;
- Results of external audits;
- Staff suggestions;
- Training records;
- Operation of the system and procedures over a reasonable historic period (6 to 12 months)

3.11 Water Systems SCART Report

The Lead Authorised Person (Water) must regularly gather and maintain all the relevant information for import into the Campus SCART system.

All evidence confirming the SCART position and justification for risk rating adjustments should be uploaded to the SCART database in electronic format.

3.12 Contractor Management & Audit Report

Contractor Management Process

Regular review meetings should be set up with any contractors working on the water distribution system. Minutes of the meetings are held on the QEUH Estates Shared Drive at the path: SGH Estates>Water Quality>Contractor Meetings.

Discussions should include:

- Ongoing works;
- Future task programme;
- Recording procedures;
- RAMS;

Contractor Competency

Regular checks should be performed to ensure that any contractors working on the water distribution system are deemed competent and all operatives are suitably trained to conduct the delegated tasks. Copies of all Risk Assessments and Method Statements should be refreshed and all training records reviewed by the Water Systems AP. Copies are stored on the QEUH Campus Shared Drive in Water Quality.

Contractor Audit Report

A report should be produced at least annually to record the findings of the audit.

3.13 Permit to Work, Water Systems.

The Permit to Work Water Systems as per this written scheme is solely intended to be used when works on the hot and cold water systems and its ancillary equipment are to be completed within the QEUH and RHC campus. This includes break-ins to existing pipe work, removal of dead legs and any new installation works.

The Permit to Work may only be issued to Competent Persons (L8 approved) by the Authorised Person (AP) for water. This includes in house maintenance staff and approved contractors.

The Permit to Work form will include the following;

- Name of the organisation issuing the permit.
- Permit number.
- Name of Authorising Person (AP), including emergency contact details.
- Reasons for the works on the water system, (Plant Preventive Maintenance, Planned repairs or Emergency works).
- Exact location of the works
- Reference to any as built drawing numbers, (for update purposes).
- Name of Competent Person (CP) undertaking the works.
- Hazards and Risks, (copy of Risk assessment and Method Statements (RAMS) to be submitted for approval before start of works)
- Commissioning and Testing.

The above points on the Permit Work are broken into five categories, namely;

Part 1 Description of work and authorisation/permission to proceed.

Part 2 CP acceptance of work and conditions.

Part 3 Confirmation of work completion and engineering test results.

Part 4 Authorisation to use a system.

Part 5 Acceptance of system status by Nurse Manager.

Procedure to be followed for Permit to Work on water systems within the QEUH and RHC;

Sign into Estates office within the Laboratory building on the QEUH and RHC campus.

Receive induction from Authorised Person water.

Provide L8 Competent Person certification to Authorised Person water.

Provide applicable RAMS for the works to be completed.

3.14 Tool Box Talk, Hot and Cold Water Systems.

Estates Tool Box Talk on Hot and Cold water Systems is located on the shared drive / water quality / Estates Tool Talk. This is carried out in the form of a power point presentation.

4.0 MAINTENANCE PROCEDURES

Procedure Reference	Operation
4.1	SYSTEM INFORMATION
4.2	MAINTENANCE PROCEDURES SUMMARY
4.3	WEEKLY MAINTENANCE TASKS
4.4	MONTHLY MAINTENANCE TASKS
4.5	QUARTERLY MAINTENANCE TASKS
4.6	SIX MONTHLY MAINTENANCE TASKS
4.7	ANNUAL MAINTENANCE TASKS
4.9	BI-ANNUAL MAINTENANCE TASKS

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific ‘Log Book’ for the location being maintained.

4.1 System Information

4.1.1 Correct and Safe Operation of the System

Measures should be in place to ensure that the water system is operated within the specific parameters as detailed in the following paragraphs:

4.1.2 Hot Water System

The storage of domestic hot water should be arranged to ensure that a water outflow temperature of at least 60°C is achieved. No two water systems are the same and through periodic monitoring operational system performance, the system outflow temperature should be set to over 60°C to ensure an outflow of 60°C is achieved under normal draw-off demand and achieve 55°C at the supply to the furthestmost draw-off point in the circulating system. It is important to maintain temperatures at above this figure (Legionellae organisms will survive for only a short period of time above this temperature - approximately two minutes).

Periodic performance monitoring and a system of continuous monitoring and recording of water temperatures via a building management system (BEMS) or data logger is essential to ensure compliant system performance.

The outflow water temperature, under prolonged maximum continuous demand (at least 20 minutes) from calorifiers should not be less than 60°C.

While it is accepted that occasionally under peak instantaneous or prolonged demand the water outflow temperature will fall, it is not acceptable if this occurs frequently (more than twice in any 24 hour period) and/or for long periods (exceeding 20 minutes).

Under no circumstances should the domestic hot water flow temperature fall below 55°C.

It is recommended that disinfection by pasteurisation is undertaken if the water temperature of the calorifier falls below 45°C. A minimum domestic hot water circulation (return) temperature of 55°C shall be maintained during the hours of occupancy.

4.1.3 Cold Water System

All domestic cold water storage cisterns and tanks shall comply with the requirements of the Scottish Water Byelaws.

Duplicate tanks often create a risk of water becoming stagnant in one of them, leading to risk of Legionella, Pseudomonas Spp or similar contamination. Consideration should be given to taking one of the tanks out of service. See guidance in “Guidance for Alterations to Water Systems”.

All cold water storage tanks are to be examined and the temperature tested on a regular summer / winter six monthly cycles and cleaned on an annual basis as required.

Temperatures in cold water storage tanks and the mains inlet to them should be checked during periods of high ambient temperatures (e.g. summer afternoons between June and August). Water temperatures should be less than 20°C.

At the same time, the furthest and nearest draw off points in the system should be checked to ensure that the water distribution temperatures are less than 20°C within 1 minute of running the water (at full flow). A similar temperature check regime should be undertaken during the winter months to identify the performance of cold water distribution systems and the impact of heat gain from heating systems.

4.1.4 Cold Water System Dump Valves

The cold water system installed in the Adult & Childrens Hospitals has a dump valve arrangement incorporated into the ground floor, 1st floor and 2nd floor layouts. The positions of the dump valves are shown on the Schneider BMS STRUXUREWARE system and connected via the KNX network.

Operating parameters for the dump valves are as follows:

Open at 23°C

Close at 20°C

4.1.5 End of Line Sensors (EOLs)

The hot and cold water system also incorporates End of Line (EOL) sensors which monitor the temperatures at specific sentinel points across all 11 floors of the Adult & Childrens installation. These can also be viewed via the Schneider BMS system.

4.1.6 Sampling

General microbiological and Legionella sampling in hot & cold water systems

Circumstances under which samples are taken:

- prior alterations to an existing water system;
- as part of commissioning process, prior to handover of a new building or introduction of a (altered, refurbished or new) water system into use;
- one week following handover of a new building or new water system;
- as part of the tank cleaning and disinfection process;
- as part of an assessment programme;
- in response to taste, odour or sustained discoloured water complaints.

When such samples are taken, a mains supply sample should be taken as a control to verify whether the supply could be the source of the identified problems. Scottish Water should also be contacted for distribution zone water quality data.

4.1.7 WS01 – Little Used Outlets

Control of Legionella in Water Systems, Intermittently used Water Outlets and Showers, Standard Operating Procedure WS01.

The Estates department is required to ensure that on a quarterly basis the list of ‘intermittent’ or ‘infrequently’ used water outlets or showers is reviewed to ensure it is accurate and up to date. Records of these reviews will be held within the system logbooks held locally.

If after investigation the taps or appliances identified within the reviewed list are deemed not necessary wherever possible the supply should be cut and the appliance removed from the water system. Where this is not possible then pipe work shall be cut back as close to the main circulating line as practicable to ensure that any dead-leg formed is minimised.

Nursing and other staff must be made aware of the issues surrounding legionella contamination and the link to low and underused water outlets and their assistance in formally identifying these possible outlets are sought.

Upon acknowledgement from the clinical staff of any intermittent or infrequently used outlets, the records are held on the Estates shared drive under Water Quality / WS01.

Any request from clinical staff regarding the removal of any intermittent or infrequently used outlets is assessed and surveyed by the AP (Water). If deemed appropriate a job is raised on FM for the Plumbing Technicians to remove, this is documented in the WS01 Records file in the Water Quality file on the shared drive. Subsequent hot and cold water pipe drawings are updated by the CAD Technician CP (water) where and when appropriate.

FILLING IN LOG SHEETS

Good water hygiene depends on maintaining high standards of cleanliness and freshness, together with careful temperature control. This section contains details of checks and recording sheets (marked “Log Sheets”) to be filled in when checks and measurements are made to show that the necessary standards are being kept up. Alternatively, where an electronic PPM system is used, Procedure references should be entered.

Follow the instructions within the boxes and make entries as each task is completed. The tasks are all listed at the front of each section e.g. weekly tasks at the front of the weekly section, monthly section, quarterly 6 monthly etc. The summary list of tasks in this section is to remind you of what is required. The Task and Log Sheets can be copied as required, completed Log Sheets will be filed where indicated in Section 2. **FM First ticket number MUST be included in all logsheets.**

PLANNING

The tasks and forms are organised into weekly, monthly, quarterly and annual sections. Always aim to carry out tasks early in the period when they are due to leave an opportunity to do them later if an emergency delays your plans.

ASK

If you have difficulties with the forms or do not understand the tasks, ask your Supervisor or line manager for clarification or guidance.

CHECKING

Incomplete or incorrect records are unacceptable in that they are misleading and do not do justice to the effort put in to achieve standards. Each log sheet includes a space for comment and tells you to check that all the boxes are complete: do make use of the comment space and double check the form, otherwise the record will have gaps and whoever is responsible for auditing will concentrate on what is missing and may not give you credit for the work that has been done.

LOG INSPECTION

Anyone inspecting this log (either as part of the Management Control System or not) is invited to make an entry in the inspection of Log Book record in front of Section One.

SURVEY

For survey purposes all surveys will be carried out starting left to right, where 2 off access doors are available the left access shall be taken first. Surveys shall be undertaken from top to bottom.

EQUIPMENT FITTINGS AND MATERIALS

Prior to carrying out alterations/ additions to distribution systems, the Water Fittings and Materials Directory published by the Water Regulations Advisory Scheme, should be consulted. This directory lists all materials and fittings approved for use to satisfy the requirements of current Water Byelaws.

Details of all new materials and fittings used in installations should be noted and recorded on the specific work document or project file for future reference.

SYSTEM ADDITIONS AND ALTERATIONS

Any additions, modifications or improvements to the water distribution system are to be noted and recorded and system record's amended to reflect such changes.

HYGIENE PRACTICES

Care should be taken to ensure high levels of personal hygiene, clean hands, clean clothing and PPE or gloves is maintained at all times when working on wholesome water operations. Tools, equipment, instrumentation and material's shall be free from contamination and appropriately disinfected before use.

Items such as pumps and hoses used in contact with water used for domestic purposes must be stored separately, clearly identified (ie colour coded or labelled) and **MUST NOT BE USED FOR ANY OTHER PURPOSE.**

Refer to Section 2.2 for location of maintenance records for the above.

4.2 Maintenance Procedures Summary

This section contains information in relation to the operational and maintenance checks managed by QEUH NHS Staff and appointed contractors to minimise the risk of exposure to *Legionella* and other waterborne micro-organisms within the domestic water systems, and to improve water quality. Procedures are as per the recommendations and exemplar models given in SHTM 04-01 Part G.

Procedure Reference	Operation(s)	Record Form Ref	Frequency
P1C1	BMS Temperature Monitoring (Carried out by NHS Estates)	Requires new number	Daily
P1CC1A	Manual Temperature Monitoring for calorifiers (different form used ONLY REQUIRED if no BMS Monitoring)	(005a)	Daily
N/A	Filtration Plant Checks (Carried out by NHS Estates)	028c	Twice Daily
WS01	Daily flushing of all outlets (Carried out by NHS Facilities)	-	Daily
WS01	Flushing of little used outlets * frequency based on risk (Carried out by NHS Clinical) see page 103	-	Daily or Twice weekly
WS01	Deluge shower/Eye wash flushing (1 off carried out by NHS Estates and 1 off by DMA)	(026)	Twice Weekly
P1C3	Pump operation/duty rotation (Carried out by NHS Estates)	(028a)	Weekly
P1C4	Temperature Recording of Sentinel Hot and Cold Water Outlets. (Carried out by NHS Estates)	(005c)	Monthly
P1C4	DHW Calorifier and Buffer Vessel Checks (Carried out by NHS Estates)	(005)	Monthly
P1C6	DWS Calorifier, Expansion Vessel Flushing (Carried out by NHS Estates)	(006) (023)	Monthly
P1C12	Showerhead/hose replacement/disinfection (No longer carried out as shower head and hoses replaced quarterly)	(005b)	Quarterly
WS01	Review of Rarely Used Water Outlets and Changes In-Use (Carried out by NHS Estates)		Quarterly
P1C9	DWS Calorifier / Expansion Vessel Inspection (Carried out by NHS Estates)	(006)	Annually
N/A	Water Services Pipework and Distribution System Checks (Carried out by NHS Estates)		Annually
N/A	Vibration coupling inspection (Carried out as part of checks on booster pumps) (Carried out by NHS Estates)		Annually
N/A	Carry out review of log books and Written Scheme		Annually (Sep)
N/A	Carry out review of drawings and schematics		Annually (Sep)

4.3 Required Maintenance Tasks (cont)

In addition to the tasks undertaken by NHS directly employed Competent Persons, there are also tasks undertaken by Contractors on a selection of buildings within the campus.

Procedure Reference	Operation(s)	Record Form Ref	Frequency
	CWST Inspection (Carried out by DMA)	DMA Records	Annually
	Hot and Cold Tap Outlet Sanitisation and Operational Checks (NOT CARRIED OUT UNLESS ISSUE IDENTIFIED THROUGH SAMPLING)	DMA Records	Annually
-	As per 6 monthly and ClO ₂ & Chlorite Probe membrane cap replacement, Dosing Pump diaphragm valve replacements, Replace ClO ₂ gas detector cartridge if required (Carried out by Scotmas)	ScotMas Records	Annually
P1C10	Representative Tap Temperature Monitoring Note: All tap temperatures are checked through TMT/TMV maintenance (Carried out by DMA)	DMA Records	Annually
P1C1 4.3.1	Daily BMS Temperature Monitoring (Carried out by Estates)	(021)	Daily
P1CC1A 4.3.2	Manual Temperature Monitoring (only required in absence of BMS) (Carried out by NHS Estates)	(005a)	Daily
4.3.3	Filtration Plant Checks (Carried out by NHS Estates)	(028c)	Twice Daily
-	Flushing all outlets (Carried out by NHS Facilities)	-	Daily
WS01	Flushing Intermittently used outlets (Carried out by DMA)	-	Twice Weekly
WS01	Flushing Deadlegs and drain valves (Carried out by DMA)	-	Twice Weekly
WS01	Deluge shower/Eye wash flushing (Carried out by DMA and NHS Estates)	(026)	Twice Weekly
P1C3	Pump operation/duty rotation (Carried out by NHS Estates)	(028a)	Weekly
P1C4	Temperature Recording of Sentinel Hot and Cold Water Outlets. (Carried out by NHS Estates)	(005c)	Monthly
-	Temperature Recording of Sentinel Hot and Cold Water Outlets for CL02 (Carried out by DMA)	-	Monthly
P1C4	DHW Calorifier and Plate Heat Exchanger Checks (Carried out by NHS Estates)	(005)	Monthly
-	PPM Schedule Monthly Visually inspect chemical delivery system, Check chemical suction and delivery lines for correct operation Chemical level check and refill, Cross check measured ClO ₂ / Chlorite residual test against analyser & Palintest Kit, Check and Adjust controller settings as required (Carried out by ScotMas)	-	Monthly
P1C6	DWS Calorifier, Expansion Vessel Flushing. (Carried out by NHS Estates)	(006) (023)	Monthly
	Replacement of PAL filters (Carried out by DMA)		31 Days or 62 Days

Procedure Reference	Operation(s)	Record Form Ref	Frequency
WQS 001	HORNE Tap Flow Restrictor Exchange (Carried out by DMA)		Quarterly
	TMV/TMT & Thermostatic Shower Disinfection and Function Test (HIGH RISK)		Quarterly
	'TMV' and Mixing Valve Sanitation and Maintenance Checks (Carried out by DMA)		Six-Monthly
	TMV/TMT & Thermostatic Shower Disinfection and Function Test (Non-HIGH RISK) (Carried out by DMA)		Six-Monthly
P1C7	CWST Inspection and Temperature Monitoring (Carried out by DMA) (Carried out by DMA)	(003)	Six-Monthly
	TMV' and Mixing Valve Sanitation and Maintenance Checks (Carried out by DMA)	DMA Records	Six-Monthly
N/A	TMV/TMT & Thermostatic Shower Disinfection and Function Test (Non-HIGH RISK) (Carried out by DMA)	DMA Records	Six-Monthly
-	Maintenance of filtration units (Carried out by Veolia)	Veolia Records	Six-Monthly
-	6 Monthly Visit– As per monthly, plus, Check ClO2 gas detector functionality and recording levels, Simulate fault circuitry and alarm on Sentinel Monitor, Change probe electrolyte and cross calibration test, Carry out manual Chlorate & Chlorite validation tests (12 representative outlets), Check water meter operation and report o Electrolyte top up, Probe calibrations (Carried out by Scotmas)	ScotMas Records	Six-Monthly
P1C7	CWST Inspection and Temperature Monitoring (Carried out by DMA)	DMA Records	Six-Monthly
N/A	TMV/TMT & Thermostatic Shower Disinfection and Function Test (Non-HIGH RISK) (Carried out by Vanguard for MIU only)	Vanguard Records	Annually
	CWST Inspection (Carried out by DMA)	-	Annually
	Hot and Cold Tap Outlet Sanitisation and Operational Checks (NOT CARRIED OUT UNLESS ISSUE IDENTIFIED THROUGH SAMPLING)	-	Annually
-	As per 6 monthly and ClO2 & Chlorite Probe membrane cap replacement, Dosing Pump diaphragm valve replacements, Replace ClO2 gas detector cartridge if required (Carried out by Scotmas)	-	Annually
P1C10	Representative Tap Temperature Monitoring Note all tap temperatures are checked through TMT/TMV maintenance (Carried out by DMA)	-	Annually
P1C9	DWS Calorifier / Expansion Vessel Inspection (Carried out by NHS Estates)	(006)	Annually
	Water Services Pipework and Distribution System Checks (Carried out by NHS Estates)		Annually
P1C10	Representative Tap Temperature Monitoring (Carried out by DMA as part of TMV checks)	(005)	Annually
	Vibration coupling inspection Carried out monthly as part of checks of Booster sets (Carried out by NHS Estates)		Annually
	BMS Sensors (Carried out by Schneider and MCE BMS Providers for respective BMS)		Annually

4.3 Daily Maintenance Tasks

Reference	Operation
4.31	BMS Temperature Monitoring
4.32	Manual Temperature Monitoring
4.33	Filtration Plant Checks

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific ‘Log Book’ for the location being maintained.

4.31 – BMS TEMPERATURE MONITORING

DAILY

FM First Template No 826

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 26 para 3.11

RECORD FORM - (021)

PROCEDURE REF - P1C1

SCHEDULE REF – BMS 01

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **DAILY** as a minimum:

Description of Works

- Refer to the BMS Temperature Monitoring Schedule BMS 01.
- Log onto both STRUXUREWARE BMS and DISTECH BMS front ends and check all temperatures from listed locations.
- Complete Schedule BMS 01 to confirm all temperatures have been checked.
- Any temperatures found outside the defined parameters stated on the BMS Temperature Monitoring Schedule should be investigated and resolved immediately. Details must be entered on Record Form (021) and escalated to the Water Systems AP.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Schedule BMS 01 and Incident form **04** if required, ensuring that you date, sign it and enter FM First ticket number.
3. Return forms to the Water Systems AP.

NOTE: Both Struxureware and Distech BMS systems are capable of generating temperature trend logs. These logs will be checked on a regular basis by the Water Systems AP to confirm accuracy of information.

4.32 – MANUAL TEMPERATURE MONITORING **(in absence of BMS)**

DAILY

FM First Template No 830

IN ACCORDANCE WITH SHTM 04-01 Part G (*VI July 2015*) Page 26 para 3.15

RECORD FORM – (005a) (021a)

PROCEDURE REF - P1CC1A

SCHEDULE REF – MTM 01

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **DAILY** as a minimum:

Description of Works

- Refer to the Manual Temperature Monitoring Schedule MTM 01.
- MANUALLY visit each location and obtain and record temperatures from all plant as listed on Schedule MTM 01.
- Any temperatures found outside the defined parameters stated on the MTM 01 Temperature Monitoring Schedule should be investigated and resolved immediately. Details must be entered on Incident Form (004a) and escalated to the Water Systems AP.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms (005a) and (004) if required, ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.33 – FILTRATION PLANT CHECKS**TWICE DAILY**

FM First Template No 836

IN ACCORDANCE WITH BOARD POLICY

RECORD FORM – (028c)**PROCEDURE REF – N/A****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **TWICE DAILY** as a minimum AM and PM:**Description of Works**

- Refer to the Filtration Plant Daily Checks Log sheet (028c).
- Complete all listed checks and ensure plant is running if selected as DUTY, or available to run if selected as STAND-BY.
- Details must be entered on Record Form (028c) and any issues escalated to the Water Systems AP immediately.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms (028c) if required, ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.4 Weekly Maintenance Checks

Reference	Operation
4.41	Flushing of Rarely Used Water Outlets (Twice Weekly)
4.42	Flushing of Deadlegs & Drain Valves (Twice Weekly)
4.43	Rotation of Water Services Duty/Stand-By Pumps
4.44	Operation and Checks to Emergency Deluge Shower/Eye Wash (Twice Weekly)

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.41 – FLUSHING OF INTERMITTENTLY USED WATER OUTLETS

FM First Template No 824

TWICE WEEKLY

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 101 para 6.36

RECORD FORM - (DMA)

PROCEDURE REF - WS01

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **TWICE WEEKLY** as a minimum:

Description of Works

- Refer to the locations listed by DMA.
- Estates to arrange for the Schedule to be updated to record on a regular basis.
- Flush water from ALL outlets identified at a minimum frequency of Twice Weekly for a minimum period of 3 minutes per tap outlet taking care not to cause splashing or exposure to water aerosols / droplets.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Form ensuring that you date, sign it.
3. DMA to send flushing records to Water Systems AP.

NOTES:

In circumstances where there has been a lapse in the flushing regime, the stagnant and potentially contaminated water from within the shower or tap and associated dead leg should be purged to drain without discharge of aerosols before the appliance is used.

NHSGG&C consider the cleaning of wash hand basins, toilets and showers etc by Domestic Services staff to fulfil the criteria of having been used /flushed.

As part of the ward/departments standard cleaning schedule Domestic Services staff will clean all wash hand basins, showers, baths, WC's and bidets. For the purposes of Legionella and Pseudomonas control the Board deems this to be considered adequate to fulfil guidance on the use of water outlets.

Facilities Management send on flushing records of all taps to Water Systems AP monthly.

Refer to Facilities Procedure - Wash Hand Basin Cleaning (including point of use filter).

4.42 – FLUSHING OF DEADLEGS & DRAIN VALVES

FM First Template No 827

TWICE WEEKLY

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 101 para 6.36

RECORD FORM - DMA

PROCEDURE REF – WS01

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **TWICE WEEKLY** as a minimum:

Description of Works

- Refer to the locations listed on Record Form (DMA).
- Estates to arrange for the Schedule to be updated to record on a regular basis.
- Flush water from ALL outlets identified on Record Form on a Weekly basis for a minimum period of 3 minutes per tap outlet taking care not to cause splashing or exposure to water aerosols / droplets. Drain Valves to be purged to ensure the removal of any built up residue in the line.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record ensuring that you date, sign it and Complete FM work request.
3. Return form to the Water Systems AP.

4.43 – ROTATION OF WATER SERVICES DUTY/STAND-BY PUMPS

FM First Template No 820

WEEKLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 27 para. 3.24**RECORD FORM - (028a)****PROCEDURE REF - P1C3****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **WEEKLY**:**Description of Works**

- Inspect and confirm operation of all listed duty/stand-by pumps by interrogating the programmer to check hours run for each pump motor.
- Check pump rig and associated valves for correct operation, signs of damage, leakage or corrosion.
- Record all details on Record Form (028a)

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Form (028a) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.44 – OPERATION AND CHECKS TO EMERGENCY DELUGE SHOWERS/EYE WASH

FM First Template No 825

TWICE WEEKLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 57**RECORD FORM - (026c) and DMA record for separate shower.****PRECEDURE REF – WS01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4**RISK CONTROL NOTICE - RCN 11/04**The following actions must be undertaken **TWICE WEEKLY**:**Description of Works**

- Refer to the locations listed on Record Form (026c) NHS only (DMA complete flushing records).
- Operate shower for a minimum period of 3 minutes taking care not to cause splashing or exposure to water aerosols / droplets. Measure and record temperatures until discharge water drops to the same temperature as the incoming mains water.

NOTE: For thermostatic showers and taps, the outlet should be flushed on the full cold setting for 2 minutes, then again on the full hot setting for a further 2 minutes, using override setting where available. Cold water should be less than 20°C, Hot water should be between 55°C and 60°C, and Mixed water in the range 41-43°C.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Form (026c) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.5 Monthly Maintenance Checks

Reference	Operation
4.51	Sentinel Outlet Temperature Recording
4.52	DWS Calorifier – Temperature Checks & Blowdown
4.53	CL02 checks

NOTE:

Completed Log Sheet to be submitted to Site Estates Manager / Authorised Person (Water) for authorisation and copies filed as indicated in Section 2.20.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific ‘Log Book’ for the location being maintained.

4.51 – SENTINEL OUTLET TEMPERATURE RECORDING

FM First Template No 828

MONTHLY

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 28 para 3.27

RECORD FORM - (005c)

PROCEDURE REF - P1C4

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **MONTHLY**:

Description of Work

- Check the temperatures at the sentinel taps as defined in the local plan of the system being checked. NOTE: Where the sentinel is a TMV or TMT the temperature readings should be taken from the pipework or directly from the hot and cold supply.
- Using a calibrated temperature probe, check the temperature of water from the cold water tap does not rise above 20°C after running the tap for 2 minutes.
- Using a calibrated temperature probe, check the temperature of water from the hot water tap does not drop below 55°C whilst running the tap for 1 minute.
- Record all temperatures on Record Form (005c).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Form **(005c)** ensuring that you date, sign it and enter FM First ticket number. Complete FM Work Request.
3. Return form to the Water Systems AP.

4.52 - DWS CALORIFIER – TEMPERATURE CHECKS & BLOWDOWN

FM First Template No 821

MONTHLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 28 para 3.30**RECORD FORM - (005)****PROCEDURE REF - P1C4****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **MONTHLY**:**Description of Work**

- MANUALLY CHECK and record the flow and return temperatures on the domestic hot water system as defined on Record Form (005), using the temperature gauges fitted or a suitable surface temperature probe.
- MANUALLY CHECK and record the calorifier storage temperature at top and bottom gauges if fitted.
- The flow temperature to be at least 60°C and the return temperature shall be no less than 55°C
- MANUALLY CHECK and record the cold water feed temperature using the temperature gauges fitted or a suitable surface temperature probe.
- Blowdown drain valves (if fitted) on all calorifiers and expansion vessels by opening the drain valve 3 times, each time for a 3 minute period. Where required, the hose from the drain valve connection should be discharged to the nearest drain/gulley. If there is no drain valve make note on Record Form 005.
- Check all local pipework to and from calorifier is in good order and all insulation is intact.
- Operate all isolation valves through their full range of motion.
- Check, confirm and record operation of de-stratification pump.
- Record all information on the Record Form (005).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Form **(005)** ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.53 – CL02 PLANT CHECKS

FM First Template N/A

MONTHLY

IN ACCORDANCE WITH SHTM 04-01

RECORD FORM – N/A**PROCEDURE REF – N/A****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **MONTHLY**:**Description of Work**

- PPM Schedule Monthly Visually inspect chemical delivery system.
- Check chemical suction and delivery lines for correct operation Chemical level check and refill.
- Cross check measured ClO₂ / Chlorite residual test against analyser & Palintest kit.
- Check and Adjust controller settings as required.

CHECK

1. Record all details of any fault or discrepancies and report to Water Lead AP who will complete Incident Form (04).

4.6 Quarterly & Other Maintenance Checks

Reference	Operation
4.61	Shower Head and Flexible Hoses Disinfection/Replacement
4.62	DHWS Calorifier and Expansion Vessel - Flush
4.63	HORNE Tap Flow Restrictor Exchange
4.64	Review of Rarely Used Water Outlets and Changes In-Use
4.65	TMV/TMT & Thermostatic Shower Disinfection and Function Test (HIGH RISK)
4.66	PAL filter replacement

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.61 SHOWER HEAD AND HOSE REPLACEMENT/DISINFECTION

FM First Template No 869
Schedules: 1997 to 2724

QUARTERLY

IN ACCORDANCE WITH SHTM 04-01 Part G (*VI July 2015*) Page 32 para 3.51

RECORD FORM -See DMA records

PROCEDURE REF - P1C12 CURRENTLY CONTRACTED TO DMA CANYON WATER

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken every **THREE MONTHS**:

NOTE: If PALL filter is fitted it must be left in place and recorded as such on DMA records)

Description of Work

- Exchange shower head and hose assembly inc sealing washers with new disposable unit. Place old shower head and hose assembly into re-sealable plastic bag.
- Check that the new head and hose package is intact;
- Open replacement new shower head and hose assembly sealed packaging, remove and fit following the manufacturer's instructions;
- Run water and flush for 3 minutes in accordance with Legionella Risk Assessment in such a way as to avoid the creation of aerosols;
- Check final temperature for compliance and working order and return shower appliance to use.
- Return redundant sealed bag with shower head and hose assembly to collection point for recycling in accordance with Waste Procedures;
- Record all actions on the Record Form (005b).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Form (005b) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

NOTE: This procedure replaces the previous Clean & Disinfect method from 1st April 2019 for majority of showers. Where fixed showers exist, eye wash stations, baths etc DMA will carry out clean disinfection of these.

Fixed Shower Head / Bath shower, eye wash shower heads**Description of Work**

- Exchange shower head and hose assembly inc sealing washers with previously cleaned and sanitised unit. Place old shower head and hose assembly into re-sealable plastic bag.
- Check that the new clean disinfected head and hose package is intact;
- Open replacement new clean disinfected shower head and hose assembly sealed packaging, remove and fit following the manufacturer's instructions;
- Run water and flush for 3 minutes in accordance with Legionella Risk Assessment in such a way as to avoid the creation of aerosols;
- Check final temperature for compliance and working order and return shower appliance to use;
- Return redundant sealed bag with shower head and hose assembly to workshop for disposal in accordance with Waste Procedures;
- Record all actions on the Record Form (005b).

CHECK

4. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
5. Complete Record Form (005b) ensuring that you date, sign it and enter FM First ticket number.
6. Return form to the Water Systems AP.

4.62 - DWS CALORIFIER AND EXPANSION VESSEL - FLUSH

FM First Template No 821

QUARTERLY

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 29 para 3.34

RECORD FORM - (006) and (023)

PROCEDURE REF - P1C6

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken every **THREE MONTHS**:

Description of Work

- Flush each Domestic Hot Water Calorifier and Buffer Vessel through its drain valve by opening the drain valve 3 times, each time for a 3 minute period. Where required, the hose from the drain valve connection should be discharged to the nearest drain/gulley.
- Record all actions on the top section of Record Form (006).
- Where the domestic hot water system has a stratification pump(s) fitted to circulate the hot water from the top to the base of the calorifier or the storage/buffer vessel, and the history data shows no sludge deposits during flushing, then this procedure should be risk assessed to determine if the maintenance frequency can be changed. This assessment should be recorded on Record Form (023).

NOTE: this flushing process can air lock the hot water system, so only carry it out when there is no hot water demand and the calorifier is valved off from the system.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms (006) and/or (023) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.63 – HORNE TAP FLOW RESTRICTOR EXCHANGE

FM First Template No N/A

QUARTERLY

IN ACCORDANCE WITH IC GUIDANCE

RECORD FORM – (See DMA Records)

PROCEDURE REF – WQS 001

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken every **THREE MONTHS**:

Description of Work

PPE:- Surgical gloves should be worn when carrying out this task. Cross contamination of the replacement flow restrictor should be considered and avoided at all times.

Restrictor should only be replaced at outlets without PALL filters. If PALL filter is fitted it should be left in place and noted on Record Form.

- Assemble all tools and materials required to complete task.
- Check with ward staff to ensure access can be granted to each area without Infection Control restriction.
- Remove existing restrictor using the appropriate tool and dispose of the restrictor in general waste.
- Use disinfectant wipes to sanitise tap outlet and tools used before re-fitting new restrictor.
- Change gloves to avoid cross contamination of new components and tools.
- Unpack new restrictor components and insert into tap as per the manufacturer's instructions.
- Test on completion and fill out log sheet to record all relevant information.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Form (DMA WATER) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.64 - REVIEW OF INTERMITTENTLY USED WATER OUTLETS/CHANGE IN-USE

IN ACCORDANCE WITH BOARD POLICY

QUARTERLY**RECORD FORM – (001) (026)****PROCEDURE REF – WS01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken every **THREE MONTHS**:**Description of Work**

- Liaise with Site Facilities Manager and Heads of Department to review existing accommodation occupancy and usage on a 3 monthly basis.
- Issue Quarterly circular email to all HoDs requesting to identify little used outlets and to confirm that they have a flushing regime implemented.
- Identify any water services outlets that are not used OR changes to the occupancy.
- Schedule to be updated to record all areas which change in-use, become unoccupied or otherwise out of use.

CHECK

1. Record all details of any dept closures or little used outlets on Record Form (001) and add outlets to flushing register.
2. Ensure outlets are brought to the attention of the maintenance person carrying out the flushing activity and details added to Record Form (026) or arrange with DMA to add to flushing requirements if required. Wards should be carrying out flushing as per requirements and provide evidence on WS01 form.
3. All completed Record Forms to be stored in the building specific Log Book.

4.65 – TMV/TMT & THERMOSTATIC SHOWER DISINFECTION AND FUNCTION TEST (HIGH RISK)

QUARTERLY

FM First Template No

IN ACCORDANCE BOARD POLICY

RECORD FORM - **REQUIRES CONFIRMATION IF THIS SHOULD BE CARRIED OUT**
THREE MONTHLY

PROCEDURE REF -

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken every **THREE MONTHS**:

Description of Work

- Examine all thermostatic taps for scale build-up or other deposits. De-scale any which are not clean.
- Check and remove any installed plastic flow straighteners from tap outlet
- Inspect and Clean and Disinfect filters / strainers by removing and immersing in a solution of 1000ppm free residual chlorine (50cc CLO2 in 5 litres of water) in water for 5 minutes.
- All HORNE Optitherm taps **MUST** have the flow straightener replaced during three monthly service tasks.
- Pasteurise outlets by over-riding thermostatic controls drawing water through each thermostatic tap until a temperature of 60°C is achieved. Run the tap at this temperature for five minutes. If this is not possible disassemble tap assembly and spray all accessible components with 'Shower Head plus' mixed to a 1:3 solution, (one part chemical, 3 parts water) or equal and approved and let stand for 5 minutes.
- Reassemble and verify fail safe operation by isolating hot and cold water supplies separately.
- Ensure thermostatic controls are re-adjusted to permit blending.
- Should controls not be able to be over-ridden, verify the temperatures at the inlet connections to the thermostatic valve utilising a contact type probe and electronic thermometer.
- Run and test tap and record hot and cold water inlet temperatures and mixed water outlet temperature.
- Log all actions.

4.66 – PAL FILTER REPLACEMENT

FM First Template No

31& 62 Day

IN ACCORDANCE WITH AGREED FILTER LOCATIONS

RECORD FORM - DMA RECORDS

PROCEDURE REF -

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken every **31 Days or 62 Days based on filter types and locations**:

Description of Work

- Replace filters prior to end date on tap and shower filters as per programme.
- Process for replacement as per DMA Procedures.
- Log all replacements as per DMA Procedures and record in DMA Records.
- Any issues should be reported to Water Lead AP.

4.7 Six Monthly Checks

Reference	Operation
4.71	TMV/TMT & Thermostatic Shower Disinfection and Function Test (Non-HIGH RISK)
4.72	CWST Inspection and Temperature Monitoring
4.73	Maintenance of filtration units
4.74	CL02 checks

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.71 – TMV/TMT & THERMOSTATIC SHOWER DISINFECTION AND FUNCTION TEST (NON HIGH RISK)

IN ACCORDANCE WITH BOARD POLICY

SIX MONTHLY

RECORD FORM -

ANNUAL FOR MIU

PROCEDURE REF -

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken every **SIX MONTHS**:

Description of Work

- Examine all thermostatic taps for scale build-up or other deposits. De-scale any which are not clean.
- Check and remove any installed plastic flow straighteners from tap outlet
- Inspect and Clean and Disinfect filters / strainers by removing and immersing in a solution of 1000ppm free residual chlorine (50cc CLO2 in 5 litres of water) in water for 5 minutes.
- All HORNE Optitherm taps MUST have the flow straightener replaced during three monthly service tasks.
- Pasteurise outlets by over-riding thermostatic controls drawing water through each thermostatic tap until a temperature of 60°C is achieved. Run the tap at this temperature for five minutes. If this is not possible disassemble tap assembly and spray all accessible components with 'Shower Head plus' mixed to a 1:3 solution, (one part chemical, 3 parts water) or equal and approved and let stand for 5 minutes.
- Reassemble and verify fail safe operation by isolating hot and cold water supplies separately.
- Ensure thermostatic controls are re-adjusted to permit blending.
- Should controls not be able to be over-ridden, verify the temperatures at the inlet connections to the thermostatic valve utilising a contact type probe and electronic thermometer.
- Run and test tap and record hot and cold water inlet temperatures and mixed water outlet temperature.
- Log all actions.

4.72 – CWST INSPECTION AND TEMPERATURE MONITORING:

FM First Template No 819

SIX MONTHLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 29 para 3.37**RECORD FORM – Carried out by DMA – refer to records****PROCEDURE REF – P1C7****HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4**The following actions must be undertaken every **SIX MONTHS** seasonally during Summer and Winter:**Description of Work**

- Inspect the tank and associated pipework including insulation, valves etc for damage or corrosion and sediment.
- Operate all isolation valves through their full range of motion.
- Check the operation of the ball-valve by pressing down on it and lifting the float to confirm that water flows and stops.
- Inspect the tank overflows if visible. Confirm that there is no blockage or other foreign material and that the mesh screen is not damaged.
- Measure and record the temperature of the water in the tanks, by dipping the thermometer into the top as far from the ball-valve as possible.
- Check and record ambient outside air temp and tank room temp.
- Check the flow and record the temperature of water feeding the tanks. There should be a steady rapid flow when the ball float is down.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Records and send information to Water Systems AP.

4.73 – MAINTENANCE OF WATER FILTRATION UNITS:

FM First Template N/A

SIX MONTHLY

N/A

RECORD FORM – Carried out by Veolia– refer to records**PROCEDURE REF – N/A****HAISCRIBE/Risk Assessment Ref – N/A**The following actions must be undertaken every **SIX MONTHS**:**Description of Work**

- Check on feedwater quality
- Check on treated water quality & flows
- The condition of valves & diaphragms
- Operational cycle simulation
- General plant condition & safety
- The condition of system pumps
- The condition of the pre-filters
- Level control function

CHECK

1. Record all details of any fault or discrepancy and pass to Water Lead AP to record on the FAULT LOG and complete Incident Form (04).

4.74 – MAINTENANCE OF CL02 PLANT:

FM First Template N/A

SIX MONTHLY

N/A

RECORD FORM – Carried out by Scotmas– refer to records**PROCEDURE REF – N/A****HAISCRIBE/Risk Assessment Ref – N/A**The following actions must be undertaken every **SIX MONTHS**:**Description of Work**

- As per monthly plus :-
- Check ClO₂ gas detector functionality and recording levels.
- Simulate fault circuitry and alarm on Sentinel Monitor.
- Change probe electrolyte and cross calibration test.
- Carry out manual Chlorate & Chlorite validation tests (12 representative outlets).
- Check water meter operation and report on Electrolyte top up, Probe calibrations

CHECK

1. Record all details of any fault or discrepancy and pass to Water Lead AP to record on the FAULT LOG and complete Incident Form (04).

4.8 Annual Maintenance Checks

Reference	Operation
4.81	DWS Calorifier / Expansion Vessel Inspection
4.82	Water Services Pipework and Distribution System Checks
4.83	Representative Tap Temperature Monitoring
4.84	Vibration coupling inspection
4.85	BMS Temperature Sensor Test and Calibration
4.86	TMT Maintenance of MIU

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.81 - DWS CALORIFIER/EXPANSION VESSEL INSPECTION

FM First Template No 821

ANNUAL

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 31 para 3.44

RECORD FORM - (006)

PROCEDURE REF - P1C9

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **ANNUALLY**

Description of Work

Follow the manufacturers' maintenance instructions from O&M manuals. Record all actions where applicable on Record Form (006) for each system.

- Isolate domestic hot water calorifier or hot, cold or chilled water storage/buffer vessel service valves;
- Heat any domestic hot water calorifier or hot water storage/buffer vessel up until the contents has reached 60°C and hold at this temperature for a period of at least 1 hour;
- Drain domestic hot water calorifier and expansion vessel and remove inspection hatch;
- Hose out the domestic hot water calorifier or hot and expansion vessel to remove any debris, scale or other deposit. Care should be taken to keep aerosols to a minimum.
- If the domestic hot water calorifier or expansion vessel does not have an inspection hatch, the pipework at the top of the vessel should be disconnected to allow the insertion of a water hose to allow debris to be washed down off internal surfaces;
- Examine the internal and external condition of the domestic hot water calorifier and expansion vessel and pipework, any defects should be reported in writing to the relevant Authorised Person (Water). The safety valve should be checked, overhauled and reset as necessary. The temperature and pressure gauges to be checked for operation.
- On completion of examination and any repairs, the domestic hot water calorifier and expansion vessel should be re-assembled and the following sequence must be undertaken:
 - Refill with cold water;
 - Drain the domestic hot water calorifier and expansion vessel;
 - Refill with cold water, leave cold feed valve open;
 - Run domestic hot water calorifier or hot water storage/buffer vessel at a temperature of 60°C for at least 1 hour. Test the operation of high limit cut-out system if fitted. Check the temperature of the calorifier/vessel top and bottom with a surface thermometer;

- Adjust any controls as necessary.
- Take bacteriological samples from the base of the calorifier and submit to GRI Water Lab for analysis. (THIS TASK TO BE CARRIED OUT BY DMA CANYON WATER)

NOTE: this flushing process can air lock the hot water system, so only carry it out when there is no hot water demand and the calorifier is valved off from the system.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms (006) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.82 - PIPEWORK AND DISTRIBUTION SYSTEM CHECKS

FM First Template No 829

ANNUAL

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 31 para 3.

RECORD FORM - (0)

PROCEDURE REF -

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **ANNUALLY**:

Estates Manager or Water Systems AP will define areas to be checked in each building.

Description of Work

- Check all accessible pipework for damage, or corrosion.
- Check for missing or damaged pipework insulation
- This is carried within the Tank Room by DMA during sampling and tank inspections monthly.
- This is carried out by NHS Estates within Plantrooms during plantroom inspections monthly
- This is carried out as per above procedures and noted on FM First PPM's..

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms as per above procedures ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.83 – REPRESENTATIVE TAP TEMPERATURE MONITORING

FM First Template No 917

ANNUAL

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 32 para 3.39

RECORD FORM - (005d)

PROCEDURE REF – P1C10

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken at regular intervals throughout the year to ensure 20% of the requirement is completed **ANNUALLY**:

Description of Work

- **OBJECTIVE:** Carry out water temperature monitoring to ensure consistency and performance of the system as per design. 20% of all outlets to be assessed annually to ensure entire system is completed within a 5 year period (*ref: SCART2 Question 54*)
- Check the temperatures at a representative number of hot and cold outlets on a rotational basis as defined in the local plan of the system being checked. Lead AP (Water) to define areas to be checked each month.
- Using a temperature probe check the temperature of the cold water tap does not go above 20°C after running the tap for 2 minutes;
- Using a temperature probe check the temperature of the hot water tap does not go below 55°C within running the tap for 1 minute;
- If the outlet being tested is protected by a TMV/TMT then temperatures should be taken directly from the supply pipework or by bypassing the thermostatic device by use of an appropriate purging kit.
- Record all temperatures and locations tested on the Record Form (005d) or if carried out by DMA to reflect in records.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms (005d) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.84 - VIBRATION COUPLING INSPECTION

FM First Template No 831

ANNUAL

IN ACCORDANCE WITH HSG 274 Part 2 (2014) Page 19 para 2.35

RECORD FORM - (008)**PROCEDURE REF – WQMS 001****HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4**The following actions must be undertaken **ANNUALLY**:**Description of Work**

- Refer to list of vibration coupling locations to be assessed.
- Visually check the condition of the coupling for any signs of leakage, deterioration or corrosion.
- Ensure flexible portion of coupling is intact and free from damage or deterioration.
- Carried out on Cold Water Booster sets as part of the inspection.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.85 – BMS TEMPERATURE SENSOR CALIBRATION**ANNUAL**

FM First Template No

IN ACCORDANCE WITH

RECORD FORM -**PROCEDURE REF –****HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4**The following actions must be undertaken **ANNUALLY**:**Description of Work**

- This task should be included in the BMS Service Contract Specification.
- All temperature sensors related to domestic hot and cold water services to be checked and calibrated annually.
- All calorifiers, storage tanks, flow and return monitoring devices.
- Include all End of Line (EOL) sensors and cold water flushing devices.
- Records should be kept and made available to the estates dept on request.

4.86 – MAINTENANCE OF WATER FILTRATION UNITS:

FM First Template N/A

ANNUAL

N/A

RECORD FORM – Carried out by Veolia– refer to records**PROCEDURE REF – N/A****HAISCRIBE/Risk Assessment Ref – N/A**The following actions must be undertaken **ANNUALLY**:**Description of Work**

- As per 6 monthly and ClO₂ & Chlorite Probe membrane cap replacement.
- Dosing Pump diaphragm valve replacements.
- Replace ClO₂ gas detector cartridge if required

CHECK

1. Record all details of any fault or discrepancy and pass to Water Lead AP to record on the FAULT LOG and complete Incident Form (04).

4.87 – TMV/TMT & THERMOSTATIC SHOWER DISINFECTION AND FUNCTION TEST (NON HIGH RISK)

IN ACCORDANCE WITH BOARD POLICY

RECORD FORM -

ANNUAL FOR MIU

PROCEDURE REF -

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **ANNUALLY** :

Description of Work

- Examine all thermostatic taps for scale build-up or other deposits. De-scale any which are not clean.
- Check and remove any installed plastic flow straighteners from tap outlet
- Inspect and Clean and Disinfect filters / strainers by removing and immersing in a solution of 1000ppm free residual chlorine (50cc CLO2 in 5 litres of water) in water for 5 minutes.
- Pasteurise outlets by over-riding thermostatic controls drawing water through each thermostatic tap until a temperature of 60°C is achieved. Run the tap at this temperature for five minutes. If this is not possible disassemble tap assembly and spray all accessible components with 'Shower Head plus' mixed to a 1:3 solution, (one part chemical, 3 parts water) or equal and approved and let stand for 5 minutes.
- Reassemble and verify fail safe operation by isolating hot and cold water supplies separately.
- Ensure thermostatic controls are re-adjusted to permit blending.
- Should controls not be able to be over-ridden, verify the temperatures at the inlet connections to the thermostatic valve utilising a contact type probe and electronic thermometer.
- Run and test tap and record hot and cold water inlet temperatures and mixed water outlet temperature.
- Log all actions.

4.9 Bi-Annual Maintenance Checks

Reference	Operation
4.91	Flexible Hose/Connection Inspection and Exchange
4.92	CWST Drop Test

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.91 – FLEXIBLE HOSE/CONNECTION INSPECTION AND EXCHANGE

FM First Template No

BI-ANNUAL

IN ACCORDANCE WITH QEUH RISK ASSESSMENT RECOMMENDATIONS 2017

RECORD FORM - (009)**PROCEDURE REF – WQMS 002****HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4**The following actions must be undertaken **ANNUALLY**:**Description of Work**

- Refer to list of flexible connection locations to be assessed as per WQMS 002.
- Visually check the condition of the coupling for any signs of leakage, deterioration or corrosion.
- Safely isolate the water services and exchange the flexible connection with a BRAND NEW UNUSED replacement.
- Apply tag/label to indicate the intended date of future replacement (todays date + 24 months)
- Record all details on the Record Form (009).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms (009) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.92 – CWST DROP TESTS

FM First Template No 819

BI-ANNUAL

IN ACCORDANCE WITH

RECORD FORM -

PROCEDURE REF -

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken **ANNUALLY**:

Description of Work

- Shut off mains cold water supply to tank.
- Record the start time and allow tank to drain naturally through usage. DO NOT OPEN THE DRAIN.
- Periodically monitor the tank until usage has reduced tank to exactly half of its starting capacity.
- Record the stop time and estimate the number of hours of storage of water in the tank.
- Record all inspection details on the Record Form (010).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and complete Incident Form (04) and report to Manager.
2. Complete Record Forms (010) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

5.0 INCIDENT AND EMERGENCY PROCEDURES

Procedure Reference	Operation
5.10	FAILURE OF CONTROL MEASURES
5.20	HIGH COLD WATER SUPPLY TEMPERATURE TO OUTLET
5.30	LOW HOT WATER SUPPLY TEMPERATURE TO OUTLET
5.40	CALORIFIER OR HEAT EXCHANGER TEMPERATURE FAULT
5.50	POSITIVE LEGIONELLA TEST RESULT
5.60	IDENTIFICATION OF LITTLE USED WATER OUTLET
5.70	EMERGENCY REPAIRS
5.80	DISINFECTION OF WATER SYSTEM
5.90	PSEUDOMONAS

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

THE FOLLOWING PAGES DESCRIBE REMEDIAL ACTIONS TO BE TAKEN IN THE EVENT OF AN INCIDENT, EMERGENCY, OUT-OF-SPECIFICATION TEST RESULT AND / OR WHERE *LEGIONELLA* HAS BEEN IDENTIFIED AND/OR BACTERIA COUNTS BEING IN EXCESS OF THE RECOMMENDED LIMITS IN THE WATER SYSTEM ARE IDENTIFIED.

The Health and Safety at Work Act places a duty on employers to ensure, so far as is reasonably practicable, the maintenance of safe working conditions without risks to health, not only to employees, but also to the general public.

The risk to personnel associated with the presence of *Legionella* depends on a number of variables and may be quite low. However, since the actions to eradicate it are straightforward and reasonably practicable, it would be wise to put them in hand without delay if *Legionella* has been identified.

When analysis confirms that the levels of bacteriological contamination are in excess of acceptable limits, and/or the presence of Coliforms or *E.coli* is identified, the procedures recommended in this section should be applied.

5.1 Failure of Control Measures:

Where any reported test result, non-compliance issue or defect is made known which affects the integrity of the water system and indicates the failure of Control Measures and / or increased risk of Legionella the following procedures shall be followed and duly recorded within Section 2.3 of this document and brought to the attention of the relevant Infection Control Team and Water Management Group.

IN ALL CASES THE INCIDENT RECORD FORM (004) SHOULD BE COMPLETED AND INSERTED IN THE BUILDING SPECIFIC WATER SAFETY LOG BOOK.

5.2 High Cold Water Supply Temperature

Incident Plan

In the event of plant failure suppliers and installers guidance should be consulted. The location of all relevant literature should be recorded in the site logbook (e.g. Mercury fault finding guidance).

Mains and Stored Water

Currently there is no legal maximum water supply temperature from the Licensed Provider. In practice the water supply temperature to boundary point will be subject to seasonal variation. In winter this would normally be expected to be in the 5°C – 10°C range and in summer up to 20°C.

The following staged risk assessment escalation procedure should be employed where the water temperature in Cold Water Storage Tanks is 20°C or higher.

Stage 1 - Verification

- Where tepid cold water occurrence (i.e. $\geq 20^{\circ}\text{C}$) is reported from any numbers of cold water outlets, from maintenance/ppm, flushing procedures, from BEMS monitoring, or from the manual monitoring of storage tanks, the person identifying, or making a report must notify the relevant Authorised Person (Water) as soon as the problem is identified and confirm this in writing within 24 hours;
- The Authorised Person (Water) should liaise with the person identifying the problem and verify the problem by independently re-checking by means of taking the water temperature of the appropriate cold water storage tank, the temperature of each incoming mains supplies at the site boundary point (and building entry points of other buildings within the QEUH campus served by the same mains lines) and the outflow distribution temperature;
- If the cold water storage temperature is confirmed as being 20°C or higher at any of the above noted points, then the Authorised Person (Water) should record this in writing as well as conducting continuous monitoring of the incoming cold water mains, the cold water storage and the outflow temperatures to establish the temperature profiles and in more detail over at least a one week period to determine the level of risk;
- If only one of the incoming mains lines is $\geq 20^{\circ}\text{C}$ the consideration should be given to switching to the other mains supply until such times as “out-of-specification” mains line has returned to compliant parameters. Ensure if either mains line is non-operational it is included in a daily flushing regime and treated as per escalation procedures to follow.
- The Authorised Person (Water) should also review the Water Safety Log Book and take into account the recent water system history specifically to include:
 - the primary water treatment levels (for mains cold water supplied with Chlorine or Chloramination treatment);
 - any water sampling results;
 - system monitoring data including temperature monitoring and water quality chlorine or chloramination checks;
 - recent maintenance history; recent alterations, changes or additions to the water system;
 - any other changes made by Duty Holders or users of the water system; On reviewing continuous monitoring temperature profiles action as Stage 2, 3 or 4 as appropriate of this escalation procedure should be undertaken. The Authorised Person (Water) will ensure that the Responsible Person (Water) is notified immediately in writing at each stage and also recorded in the Water Safety log book.

Stage 2 - Initial Action – High Incoming Mains Cold Water Temperature

- Where the incoming mains cold water is 18°C or higher for more than a 48 hour period the Responsible Person (Water) should contact Business Stream (the Licensed Provider) who will work with Scottish Water to establish the reasons and determine a resolution. Continuous monitoring should continue and recorded in the risk assessment

Stage 3 - Water temperatures fluctuating above and below 20°C (but not higher than 25°C)

- Where water temperatures are fluctuating above and below 20°C in a regular cyclical manner over 72 hour periods in response to regular user water demand (but not higher than 25°C) and are more than 2°C higher than the incoming cold water mains supply temperature at the building entry point, then continuous monitoring should be continued by the Authorised Person (Water). The reason(s) for failure(s) should be identified and rectified as soon as possible. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there may be increased risk and appropriate actions may be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained).
- considerations for failures include:
 - accuracy of temperature sensors (requiring recalibration);
 - temperature sensors being located in water (requiring reposition where tank storage levels been reduced and sensor no longer sensing stored water);
 - inappropriate standby tank configuration;
 - temperature sensor in standby system;
 - temperature sensor measuring stagnation (requires reposition);
 - inappropriate siting (not in a cool location);
 - heat gain to the tank and pipework (due to lack of appropriate insulation or located close to heat gain from other heat sources);
 - storage capacity not minimised to match daily use (12 hours storage is recommended);
 - ingress of hot water through cross connection or mixing valve failure (i.e. from DHW system or MTHW systems);

Stage 4 - water temperatures fluctuating above and below 25°C (and rarely below 20°C)

- In this situation continuous monitoring should be continued by the Authorised Person (Water), the reason(s) for failure(s) (as Stage 3) identified and rectified on an urgent basis. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there will be an increased risk and appropriate actions will be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained);
- In this situation a permanent solution, such as ventilation for the plant room, or changing the water storage arrangements, or forming a circulating distribution system (with or without chilling depending on the circumstances) would require to be implemented;
- The Authorised Person (Water) should, unless instructed in writing to the contrary by Responsible Person (Water) implement the following:
 - o arrange to drain the tank contents and clean if necessary (*and/or carry out local disinfections where appropriate*);
 - o inform the users of the failed system that they must not draw off any water from the affected system until further notice;
 - o suitable disinfection of the tank and/or distribution system shall be carried out.

Please Note: *Due to the system design and installation complete disinfection of all downservices fed from the Raw and Bulk water storage tanks may not be practical as “high risk” system such as renal dialysis is fed from these tanks. Alternative protocols/method statements for local disinfections should be prepared and maintained;*

- o thereafter the tank/local area being disinfected shall be brought back into service;
- o finally the users shall be informed that the system is back in operation.

The Authorised Person (Water) shall complete an Incident Report Record Form. An entry should also be made in the Water Safety Log Book and the Responsible Person (Water) should be notified in writing as soon as possible.

5.3 Low Hot Water Supply Temperature

Incident Plan

In the event of plant failure suppliers and installers guidance should be consulted. The location of all relevant literature should be recorded in the site logbook (e.g. Mercury fault finding guidance).

Mains and Stored Water

Currently there is no legal maximum water supply temperature from the Licensed Provider. In practice the water supply temperature to boundary point will be subject to seasonal variation. In winter this would normally be expected to be in the 5°C – 10°C range and in summer up to 20°C.

The following staged risk assessment escalation procedure should be employed where the water temperature in Cold Water Storage Tanks is 20°C or higher.

Stage 1 - Verification

- Where tepid cold water occurrence (i.e. $\geq 20^{\circ}\text{C}$) is reported from any numbers of cold water outlets, from maintenance/ppm, flushing procedures, from BEMS monitoring, or from the manual monitoring of storage tanks, the person identifying, or making a report must notify the relevant Authorised Person (Water) as soon as the problem is identified and confirm this in writing within 24 hours;
- The Authorised Person (Water) should liaise with the person identifying the problem and verify the problem by independently re-checking by means of taking the water temperature of the appropriate cold water storage tank, the temperature of each incoming mains supplies at the site boundary point (and building entry points of other buildings within the Southern General Hospital served by the same mains lines⁸) and the outflow distribution temperature;
- If the cold water storage temperature is confirmed as being 20°C or higher at any of the above noted points, then the Authorised Person (Water) should record this in writing as well as conducting continuous monitoring of the incoming cold water mains, the cold water storage and the outflow temperatures to establish the temperature profiles and in more detail over at least a one week period to determine the level of risk;
- If only one of the incoming mains lines is $\geq 20^{\circ}\text{C}$ the consideration should be given to switching to the other mains supply until such times as “out-of-specification” mains line has returned to compliant parameters. Ensure if either mains line is non-operational it is included in a daily flushing regime and treated as per escalation procedures to follow.
- The Authorised Person (Water) should also review the Water Safety Log Book and take into account the recent water system history specifically to include:
 - the primary water treatment levels (for mains cold water supplied with Chlorine or Chloramination treatment);

- any water sampling results;
- system monitoring data including temperature monitoring and water quality chlorine or chloramination checks;
- recent maintenance history; recent alterations, changes or additions to the water system;
- any other changes made by Duty Holders or users of the water system;

On reviewing continuous monitoring temperature profiles action as Stage 2, 3 or 4 as appropriate of this escalation procedure should be undertaken. The Authorised Person (Water) will ensure that the Responsible Person (Water) is notified immediately in writing at each stage and also recorded in the Logbook via Incident form (04).

Stage 2 - Initial Action – High Incoming Mains Cold Water Temperature

- Where the incoming mains cold water is 18°C or higher for more than a 48 hour period the Responsible Person (Water) should contact Business Stream (the Licensed Provider) who will work with Scottish Water to establish the reasons and determine a resolution. Continuous monitoring should continue and recorded in the risk assessment.
-

Stage 3 - water temperatures fluctuating above and below 20°C (but not higher than 25°C)

- Where water temperatures are fluctuating above and below 20°C in a regular cyclical manner over 72 hour periods in response to regular user water demand (but not higher than 25°C) and are more than 2°C higher than the incoming cold water mains supply temperature at the building entry point, then continuous monitoring should be continued by the Authorised Person (Water). The reason(s) for failure(s) should be identified and rectified as soon as possible. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there may be increased risk and appropriate actions may be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained).
- considerations for failures include:
 - accuracy of temperature sensors (requiring recalibration);
 - temperature sensors being located in water (requiring reposition where tank storage levels been reduced and sensor no longer sensing stored water);
 - inappropriate standby tank configuration;
 - temperature sensor in standby system;
 - temperature sensor measuring stagnation (requires reposition);
 - inappropriate siting (not in a cool location);
 - heat gain to the tank and pipework (due to lack of appropriate insulation or located close to heat gain from other heat sources);
 - storage capacity not minimised to match daily use (12 hours storage is recommended);
 - ingress of hot water through cross connection or mixing valve failure (i.e. from DHW system or MTHW systems);

Stage 4 - water temperatures fluctuating above and below 25°C (and rarely below 20°C)

- In this situation continuous monitoring should be continued by the Authorised Person (Water), the reason(s) for failure(s) (as Stage 3) identified and rectified on an urgent basis. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there will be an increased risk and appropriate actions will be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained);
- In this situation a permanent solution, such as ventilation for the plant room, or changing the water storage arrangements, or forming a circulating distribution system (with or without chilling depending on the circumstances) would require to be implemented;
- The Authorised Person (Water) should, unless instructed in writing to the contrary by Responsible Person (Water) implement the following:
 - o arrange to drain the tank contents and clean if necessary (*and/or carry out local disinfections where appropriate*);
 - o inform the users of the failed system that they must not draw off any water from the affected system until further notice;
 - o suitable disinfection of the tank and/or distribution system shall be carried out.

Please Note: *Due to the system design and installation complete disinfection of all downservices fed from the Raw and Bulk water storage tanks may not be practical as “high risk” system such as renal dialysis is fed from these tanks. Alternative protocols/method statements for local disinfections should be prepared and maintained;*

- thereafter the tank/local area being disinfected shall be brought back into service;
- finally the users shall be informed that the system is back in operation.

The Authorised Person (Water) shall complete an Incident Report Record Form. An entry should also be made in the Water Safety Log Book and the Responsible Person (Water) should be notified in writing as soon as possible. Record on Incident form (04).

Hot Water Services

When hot water storage or distribution temperatures fall below those required (60°C storage, 55°C at outlets and returning to calorifier) these will almost inevitably be caused a mechanical fault. Appropriate maintenance procedures, including the Mercury Fault Finding guidance documents, should be created and referenced to assist in timely rectification.

This escalation procedure (taken from SHTM 04-01 Part G (Draft)) should be employed if the Calorifier/Plate Heat Exchangers outflow temperature falls below 45°C.

The table below should be used to decide on the actions necessary in the event of a plant breakdown such as power failure or gas supply failure.

Breakdown leading to temperature <45°C, lasting for:	Risk Category	Action
<12 hrs	High	Verify
	Significant	Verify
	Moderate	Verify
>12 hrs	High	Thermally pasteurise
	Significant	Verify
	Moderate	Verify
>24 hrs	High	Thermally pasteurise
	Significant	Thermally pasteurise
	Moderate	Verify
>72 hrs	High	Thermally pasteurise
	Significant	Thermally pasteurise
	Moderate	Thermally pasteurise

In the event of a reduction in domestic hot water temperature the **Authorised Person (Water)** should be notified in writing as soon as possible. The reason for failure must be identified and rectified as soon as possible.

The **Authorised Person (Water)** shall notify the **Duty Holder** and users on the failed system that they must not draw off any hot water from the affected services until further notice.

The relevant **Duty Holder** shall ensure that their staff are aware of the situation, and that they in turn shall prevent patients from using affected services.

Where thermal pasteurisation is to be carried out, the temperature of the calorifier or plate heat exchanger shall be raised to 70°C, and the water shall be circulated throughout the affected distribution system for at least one 1 hour. Each tap or appliance should be run in sequence until full temperature is achieved (this should be measured). To be effective the temperature in the calorifier or plate heat exchanger should be high enough to ensure that all distribution outlets receive water at a temperature of greater than 60°C. Ensure the return flow to the calorifier or plate heat exchanger is no less than 55°C.

The **Authorised Person (Water)** shall inform users that the system is back in operation. Bacteriological samples should be taken in consultation with the Infection Prevention and Control team. The **Authorised Person (Water)** shall complete an Incident Report Record and ensure the **Responsible Person (Water)** is notified in writing as soon as possible. Maintain hard copy records in the Water Safety Log.

5.4 Positive Legionella Test Result

Microbiological Sampling (Legionella)

Sampling requirements and frequency are to be formulated by NHS GG&C and written scheme should be updated as appropriate.

Legionella testing may be required:

- In systems where the temperature control regimes are not consistently achieved, frequent testing e.g. weekly should be carried out to provide early warning of loss of control. Once the system is brought back under control as demonstrated by monitoring, the frequency of testing should be reviewed
- Weekly checks are recommended until the system is brought under control;
- When an outbreak is suspected or has been identified;
- In wards with at-risk patients – for example those who are immuno-compromised (“high risk patient” areas still to be confirmed to DMA).

As a minimum, samples should be taken as follows:

- From the cold water storage and the furthestmost outlet from the tank, on every loop;
- From the calorifier flow, or the closest tap to the calorifier, and the furthestmost tap on the hot water service circulating system (these should be identified on sentinel outlet register);
- Additional samples should be taken from the base of the calorifier via drain valves;
- From areas where the target control parameters are not met (i.e. where temperatures are below 55°C for hot water systems or $\geq 20^{\circ}\text{C}$ for cold water systems);
- From areas subject to low usage, stagnation, excess storage capacity, dead legs, excessive heat loss, crossflow from the water system or other anomaly.
- High Risk Patient Areas
- Additional random samples may also be considered appropriate where systems are known to be susceptible to colonisation.

The temperature control regime is the preferred strategy for reducing the risk from *Legionella* and other waterborne organisms in water systems. This will require monitoring on a regular basis. The recommended test frequencies for various outlets are set out in Table 2 in Section 7.

HSG 274 Part 2 Table 2.3 Actions to be taken following legionella sampling in hot and cold water systems in healthcare premises with susceptible patients

Legionella bacteria (cfu/Litre)	Action required
More than 100 but less than 1,000	Low risk area Estates action only If only one or two samples are positive, system should be re-sampled. If a similar count is found again, a review should be carried out to identify any remedial actions a) If the majority of samples are positive, the system may be colonised, albeit at low level, with Legionella. Disinfection of the system should be considered but an immediate review of control measures and risk assessment should be carried out to identify any other remedial actions required. If remedial action is ineffective further measures will be discussed and approved by the Board Water Safety Group
More than 100 but less than 1,000	High Risk areas Impact on patient care Discuss results with ICD and agree actions and any closure of area.
More than 1,000	Low Risk Estates action only The system should be re-sampled and an immediate review of the control measures and risk assessment carried out to identify any remedial actions, including possible disinfection of the system. If remedial action is ineffective further measures will be discussed and approved by the Board Water Safety Group
More than 1,000	High Risk areas Discuss results with ICD and agree actions and any closure of area.

Communication pathway for Legionella results from water samples:

Water samples are sent to; UKASS-accredited laboratories which provide this service for NHS and other organisations that manage buildings. Reports will come back initially to the estates department.

Negative water samples are recorded as part of the documentation of Legionella control. If they are related to investigation of an “incident” such as a clinical case or a previous positive sample then these results are communicated to those managing that incident.

The information on the report which needs to be communicated is:

- Date of sampling
- Location and type of water outlet
- Identification of the organism, (Legionella pneumophila with serogroup, or Legionella species other than L pneumophila.)
- Count of organisms per Litre.

Estates will

- Inspect the system and take further action in accordance with HSE guidance and locally agreed procedures
- Inform Charge Nurse and or Clinical Nurse Manager of the Clinical Area concerned if appropriate of any control measures being taken/required
- Inform GM for the Sector if appropriate.

The results of this initial risk assessment must be communicated to all those noted above and also to the Facilities General Manager for the site involved.

The Infection Control Manager for Infection Prevention and Control will inform NHS GG&C

If there is impact on patient care then an Incident Management Team (IMT) may be convened to assess the risk and further actions.

Refer to WQS – 017 for out of spec procedure

See table in Appendix 2

5.5 Intermittent or Infrequently Used Water Outlets

If after investigation the taps or appliances identified within the reviewed list, to be updated on a quarterly basis, is deemed not necessary wherever possible the supply pipe work shall be cut back as close to the main circulating line as practicable to ensure that any dead leg formed is minimised and the appliance is removed from the water system.

In circumstances where there has been a lapse in the flushing regime, the stagnant and potentially contaminated water from within the shower or tap and associated dead leg should be purged to drain without discharge of aerosols before the appliance is used.

Where a ward or department is closed or taken out-of-use for an extended period of time e.g.: pending refurbishment, change in-use or other reason, arrangements shall be put in place to ensure the regular flushing and recording of water outlets within such areas. If such closures are considered to be long term or permanent consideration should be given to the disconnection of all water services to the affected areas.

5.6 Emergency Repairs

Emergency repairs may be required at any time and should be undertaken by trained and competent personnel. Such repairs can vary from a simple repair to a section of pipework, replacement of a component or major burst or loss of service. In all such cases the integrity and safety of the water distribution system must be maintained at all times.

5.7 Disinfection of Water System and Components

There are a number of different chemical and thermal disinfection methods available ALL of which shall be undertaken by trained and competent personnel in strict accordance with all Statutory Requirements, Safety Precautions and Manufacturers Instructions.

Disinfection – is the process of destroying or inactivating Pathogenic organisms and is generally applied to the water supply.

Sterilisation – is the process of destroying or inactivating all Organic Life Forms and is generally applied to all systems of transmission and storage materials.

In ALL instances no matter what disinfection method is employed, due regard shall be taken of patient groups, specialist equipment and processes which may be sensitive to the disinfection process being used – eg Renal Dialysis patients **must not** be exposed to Silver Hydrogen Peroxide chemicals as such the RO Water Treatment Plant and Dialysis Machines must be disconnected from the water system until the disinfection process is completed.

Silver Hydrogen Peroxide should NOT be used for a period of 90 days or longer, as required by the Drinking Water Inspectorate.

The disinfection process may be required for the following situations:

REPAIRS -	Repair fittings and exposed pipe ends should be clean and disinfected before use. Such items should be sprayed with a suitable disinfection solution such as a Sodium Hypochlorite @ a strength of 1000 mg/l (1000ppm) with a minimum contact time of 5 minutes or equal and approved.
MINOR ALTERATIONS -	Pipework should be cleaned internally by spraying with a suitable disinfection solution such as a Sodium Hypochlorite @ a strength of 1000 mg/l (1000ppm) or where pipes are long and internal surfaces cannot be reached with sprays then a swab soaked in a solution of 50mg/l (50ppm) with a contact time of one hour or equal and approved.
NEW SUPPLY PIPEWORK -	Pipes are filled with a solution such as a Sodium Hypochlorite @ a strength of 20 mg/l (20ppm) with a contact time of 24 hours. Or Sodium Hypochlorite and water at a strength of 50mg/l (50ppm) for a contact period of one hour. Minimum free chlorine after one hour – 30mg/l (30ppm) or equal and approved
SYSTEM DISINFECTION -	This will include water storage tanks and possibly the water distribution system. The advice and use of Legionella Control Association (LCA) approved contractors will be used for this purpose

NOTE:

Appropriate Method Statements and Risk Assessments will be compiled and obtained prior to any disinfection process commencing. Water Disinfection Risk Based Assessment Form (024) should be completed prior to any disinfection process being carried out. (SHTM 04-01 Part G (V1 July 2015) Page 38 para 5.9)

An alternative to chemical disinfection is to pasteurise the system. This involves increasing the temperature to greater than 60°C by increasing the thermostat setting at the calorifier or boiler and recirculation as necessary to maintain this temperature throughout for at least one hour. This should effectively sterilise the calorifier, and kill any *Legionella* organisms present.

The water should be flushed through the system more than once. It is important that all taps are run for at least 5 minutes (preferably longer) at full temperature to ensure that the complete system is pasteurised and that the hot water has reached all parts of the system.

5.8 Pseudomonas SOP

Standard Operating Procedure for minimising the risk of Pseudomonas

This SOP provides direction and guidance for ward based staff to meet their responsibilities as stated in *HPS(2013) Guidance for neonatal units (NNUs) (levels 1,2&3), adult and paediatric intensive care units (ICUs) in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water*. This document refers to critical control points 2 – 4 (inclusive) only. (Critical points 1, 5 and 6 are considered in the NHSGGC Water Safety Policy 2013.

*High Dependency Units (HDUs) which are adjoining/ integrated with an ICU should be included in this guidance.

Responsibilities:

Senior Charge Nurses (SCNs) must:

- Follow this SOP.
- Ensure that they are aware of access issues to wash hand basins. Where access is an issue they must arrange for flushing to occur and document this.
- Keep records of daily flushing for at least one month within the Facilities Folder.
- Inform a member of the local Estates Team if this SOP cannot be followed in relation to flushing water outlets.
- Inform a member of the local Estates Team of infrequently used outlets which could be removed.
- Allow members of the local Estates Team access to complete maintenance as appropriate.

Estates must:

- Undertake actions deemed the responsibility of the local Estates Department as per the Water Safety Policy.
- Keep a record of outlets reported that are deemed to be infrequently used and actions taken by them to remove this risk.
- Provide a report of maintenance actions and issues/ anomalies to the Sector Water Safety Group.
- Support staff locally to undertake their responsibilities in terms of reducing risk associated with pseudomonas.

Domestic Services must:

- Ensure that water outlets are flushed at full flow for 1 minute (not causing splashing) as part of the cleaning process and to ensure for Mixer taps that this ensures an equal mix of cold and hot. If full flow cannot be achieved taps should be flushed for a longer period following assessment.
- Ensure this is the first task completed of the day.
- Record this in the Domestic services Compliance Checklist “Water Outlets”
- Ensure the Checklist is retained within the facilities Folder at ward level for one month.
- Send a copy of flushing records to Water AP and to ensure any rooms/areas which were not flushed are identified.
- Domestic Services Supervisors and Managers must also notify Estates LAP, if they identify any unused areas or outlets as per SHTM04-01 Part G Section 8.3.

Managers must:

- Make this SOP available to their staff.
- Support SCNs in following this SOP.

Water Systems Group must:

- Keep this SOP up-to-date.
- Audit compliance with this SOP.
- Provide guidance via the Water Systems Policy.

5.9 Flushing Water Outlets

Flushing of water outlets is necessary to control the build-up of biofilm in water systems to reduce the risk of transmission of pathogens via the environment and equipment to patients.

The Senior Charge Nurse (SCN) in each unit has responsibility (under current guidance) to ensure that the following recommendations are complied with in their area. The SCN should ensure that:

All little used outlets outlets that are not used at least twice weekly in general areas and daily on high risk area identified on WS01a form. These must be flushed at full flow (but not so that splashing goes beyond the basin. However if taps cannot be flushed on full flow they should be flushed for longer based on specific assessment. The manager responsible for the ward or department must put systems in place for the outlet to be flushed to waste for 3 minutes as per SHTM04-01 Part G Page 111.

Where the outlet may be used by high-risk patients, more frequent flushing may be needed and the frequency should be determined following a risk assessment.

Additionally high high-risk environments (adult, paediatric and Neonatal ICUs and associated HDU's), flushed daily, first thing in am for 1 minute at full flow (but not so that splashing goes beyond the basin). However if taps cannot be flushed on full flow they should be flushed for longer based on specific assessment.

Additionally Facilities (Domestic Services) to ensure that all water outlets are flushed daily where access is available and all outlets flushed for 1 minute at full flow (but not so that splashing goes beyond the basin). However if taps cannot be flushed on full flow they should be flushed for longer based on specific assessment. Records must reflect where access is not available or outlets not able to flush e.g. rooms/areas under Estates, Minor Works, Capital or no access at the weekend.

Domestic Services Supervisors and Managers will also notify Estates if they identify any unused areas or outlets or outlets not able to flush as per requirements of *SHTM04-01 Part G Section 8.3*.

These should be reflected on the department flushing records.

These must be reviewed on a daily basis by the SCN and appropriate action taken when this is identified as not having been completed.

Any problems or concerns relating to the safety, maintenance, reduced usage, any changes in use and cleanliness of all water outlets are identified and reported to the ICT, Facilities and Estates Department as relevant.

- Sampling standards.
- Waste sampling out of specification definition.
- Designated High Risk Areas.

Appendix 3

Risk Assessment Review Guidance

Summary of L8 Management Tasks Required for L8 and SHTM 04-01 Compliance	Guidance Documents	Allocated to
Regular check to ensure that legislation and guidance has not changed	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of all policies relating to legionella control (e.g. Maintenance, Water Treatment, Water Management, Energy) to ensure still valid and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of L8 Management Structure to ensure up-to-date and accurate	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of communication lines to ensure still accurate and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of escalation & emergency procedures to ensure still valid and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of duties allocated to site staff and ensure accurate and recorded	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of duties of sub-contractors and ensure accurate and recorded and contractors are suitably qualified/competent for tasks assigned to them (e.g. Water Hygiene contractors should be LCA Approved, Plumbing contractors should be SNIPEF and Water Safe Registered)	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of staff training requirements and update training matrix	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of method statements and risk assessments to ensure still valid and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of site documentation to ensure all records up to date and present	L8 HSG 274 Pt 2 SHTM 04-01	
Regular update of "Patient Risk Rating" register for all areas of hospital.	SHTM 04-01 Part B	
Regular review of sentinel outlet locations register.	SHTM 04-01 Part B	
Regular review of primary, sub-ordinate and tertiary hot flow and return loops to reflect any system alterations.	HSG 274 Pt 2	
Regular review of plant and equipment maintenance schedules.	Manufacturer's Instructions	
Regular review of BEMS temperature sensor locations to reflect any system alterations	HSG 274 Pt 2	
Regular review of schematic/as-fitted drawings to ensure up-to-date and accurate	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of L8 risk assessment with a maximum period of two years between updates. (e.g. if change of use or changes in legislation or any other factor which could affect validity of current assessment)	L8 SHTM 04-01	

Appendix 4

HAISCRIBE Risk Assessments

All relevant HAISCRIBE risk assessments produced and approved for Water Systems related tasks are stored on the QEUH Shared Drive within the folder path “

HAI SCRIBE

Water Systems Safety Policy

**(To be read in conjunction with NHSGG&C Water
Safety Written Scheme and Operational Procedures)**

Lead Manager	Associate Director Facilities & Infection Control Manager

1.0 Introduction

NHS GG&C has a duty to protect all patients, employees, contractors, voluntary workers, visitors as well as members of the public from the risk of being infected by bacteria or pathogens which occur naturally in water supply systems and water dispensing equipment

Those that should be considered at risk and vulnerable include:

- Vulnerable patients with suppressed immune systems as defined and agreed by Sector Water Safety Groups and the Board Water Safety Group in all locations.

2.0 Scope

NHSGG&C has established a system of control for the management of water systems that shall ensure the safety of those within its premises by putting in place, both physical and procedural controls.

These controls shall be systematically examined and monitored by the Facilities Directorate, Infection Control, Health and Safety Department and the Board Water Safety Group which is a sub group of the Board Infection Control Committee.

This policy shall apply to all NHSGG&C managed and controlled premises.

3.0 Roles and Responsibilities

3.1 Chief Executive – Duty Holder

The Chief Executive (CE) has ultimate responsibility / accountability for water system safety within NHSGG&C.

The responsibilities of the Chief Executive (CE) include:

- Responsibility for implementation of the relevant mandatory and statutory elements contained in the following documents;
 - Health & Safety Commissions Approved Code of Practice and Guidance L8 (ACOP L8) - “Legionnaires Disease, The control of legionella bacteria in water systems”;
 - HSG 274 Part 2 – “Legionnaires Disease, The control of legionella bacteria in hot and cold water systems”;
 - HSG 274 Part 3 – “Legionnaires Disease, Technical guidance, The control of legionella bacteria in other risk systems”;
 - SHTM 04-01: The control of Legionella, hygiene, safe, hot water, cold water and drinking water systems;
 - CEL 08(2013) water sources and potential risk to patients in high risk units – revised guidance.
 - The implementation of Guidance for neonatal units (NNU’s) (levels 1, 2 & 3) adult and paediatric intensive units ICU’s in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water.

- Ensuring that adequate resources are provided to meet the Water Systems Safety requirements of NHS GG&C estate;
- Ensuring that the Water Systems Safety Policy is being implemented at all levels;
- Reviewing and monitoring the operation of the Water Systems Safety Policy through the Board Corporate Management Team and ensuring that clear guidelines are provided for this tasked with compliance of legislative and statutory standards;
- Appointing the Designated person (Pseudomonas) and Designated person (Water) to assist in the execution of these responsibilities, who for NHS GG&C are the Infection Control Manager (Pseudomonas) and the Director of Facilities (Water).

3.2 Director of Property, Procurement & Facilities Management – Designated Person (Water)

The Director of Property, Procurement & Facilities Management is the Designated Person (Water). He shall be responsible for the following and if required delegate appropriately:

- Ensuring that Facilities staff, through the general management structure, are fully aware of the current statutory and mandatory requirements and standards for the provision and maintenance of safe water systems;
- Ensuring with the Responsible Person (Pseudomonas) that the Water System Safety Policy is regularly reviewed and updated;
- Co-Chair the NHS GG&C Water Systems Safety Group;
- Appointing in writing the Responsible Person (Water) at sector level (Sector Estates Manager), Deputy Responsible Person(s) (Water) at site level (Site Maintenance/Estates Manager) and the Authorised Person (AP) (Water) at site level within the Facilities Directorate Management structure.

3.3 Infection Control Manager – Designated Person (Pseudomonas)

The Infection Control Manager (ICM) supported by the Board Infection Control Doctor is the Responsible Person (Pseudomonas). They shall be responsible for:

- Ensuring that Infection Control Teams are fully aware of current guidance on Legionella control matters and the minimisation of the risk of Pseudomonas aeruginosa infection from water;
- The implementation of Guidance for neonatal units (NNU's) (levels 1, 2 & 3) adult and paediatric intensive care units ICU's in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water;
- Ensuring with the Designated Person (Water) that the Water System Safety Policy is regularly reviewed and updated;
- Co-Chair the NHS GG&C Water Systems Safety Group;
- Appointing in writing the Responsible Person(s) (Pseudomonas) at sector level. This shall be the relevant Infection Control Doctor.

3.4 Sector Estates Manager – Responsible Person (Water)

The Sector Estates Manager (SEM) will be appointed as the Responsible Person (Water) at Sector level by the Director of Property, Procurement & Facilities Management in writing. The Sector Estates Manager is responsible for:

- Ensuring the effective maintenance of engineering controls installed for the purposes of controlling water systems;
- Ensuring that written schemes and risk assessments are in place and reviewed regularly;
- Devising and maintaining procedures to ensure the quality of water on premises is maintained;
- Ensuring operational procedures are carried out and documented;
- Ensuring records are kept of all water systems and their purpose, giving locations recording and maintaining within the Boards estates management system;
- Liaise closely with other professionals to ensure legislative and statutory compliance is maintained by the Board.

3.5 Authorising Engineer (AE)

The Authorising Engineer (AE) is appointed in writing (or as delegated by) the Director of Property, Procurement & Facilities Management and is employed independently of NHS Boards and acts as an independent professional advisor to the healthcare organisation, appointed by the organisation with a brief to provide services in accordance with Scottish Health Technical Memorandum (SHTM) 04-01 guidance.

The AE will have specialist knowledge of large scale domestic and commercial hot and cold water services installations including incoming supplies, fire fighting services, wet risers, etc., and in particular, these installations for which an Authorised person (AP) (Water) will assume responsibility for an appointment.

The AE (Water) is free to comment on the organisational risk basis and give guidance on the numbers of AP (Water) being proposed by NHSGG&C across sites.

The Authorising Engineer will carry out the following main duties:

- act as an assessor, making recommendations for the appointment of Authorised Persons (AP) (Water) in terms of skills, training and site familiarity;
- monitor the performance of the service against ACoP L8, HSG274 and SHTM 04-01 guidance;
- provide an annual audit to the organisation's Designated Person.

3.6 Authorised Person (Water)

The Authorised Person (Water) has the key operational responsibility for the service, qualified, sufficiently experienced and skilled for the purpose. He/she will be nominated by the Authorising Engineer (AE) and be able to demonstrate

- His/her application through familiarisation with the system and attendance at an appropriate professional course;
- A sufficient level of experience;
- Evidence of knowledge and skills.

An important element of the Authorised Person (Water) role is the maintenance of records, quality of service and maintenance of system safety (integrity).

The Authorised Person (Water) will also be responsible for establishing and maintaining the roles and validation of Competent Persons (Water) who shall be suitable trained employees of the organisation or appointed contractors.

Larger sites may require more than one Authorised Person (Water) for a particular service.

3.7 Senior General Manager – Property & Capital Planning – Deputy Responsible Person (Water)

The Senior General Manager – Property & Capital Planning will be appointed as a Deputy Responsible Person (Water) at Board level by the Director of Property, Procurement & Facilities Management or his delegated Manager in writing. The Head of Capital Planning is responsible for:

- Ensuring that any new works undertaken or refurbishment within existing premises shall comply with the requirements of this Policy and the Written Scheme and Operational Procedure for managing Water Safety including The control of legionella, hygiene, 'safe' hot water, cold water and drinking Water systems;
- Ensuring all works are handed over to estates in compliance with the handover protocol for water as identified in the written scheme;
- Ensuring that all potential interfaces between an operating system are new and refurbishment works shall meet the approval of the Responsible Person (Water) and Authorised Person (Water) as to methodology for making that interface;
- Ensuring that any work involving the installation of water services or equipment requiring a water supply shall follow the guidance in SHTM 04-01, HSG274 Parts 2 & 3 and HSE document L8 and shall be certified by the design engineer at to that compliance;
- Ensuring that any works which will affect an operational water service will be discussed with the estates Authorised Person (Water) prior to arranging that work.
-

3.8 Site Maintenance Manager/Site Estates Manager – Deputy Responsible Person (Water)

The Site Maintenance Manager/Site Estates Manager shall be appointed in writing by the Director of Property, Procurement & Facilities Management in writing as the Deputy Responsible Person (Water) and will also act as the Designated Person Water in the absence of the Designated Person (Water). The Site Maintenance Manager/Site Estates Manager is responsible for:

- Ensuring building water systems are operated in accordance with the current guidance, and with the assessed risk of the individual systems under their control;
- Ensuring all staff conducting water system maintenance are competent to do so;
- Ensuring water system maintenance records are maintained and kept up-to-date;
- Regularly checking maintenance records;
- Ensuring all work is completed in accordance with the NHS GG&C Estates Procedures.

3.9 Acute Services Directors, CH(C)P Directors and Corporate Division Directors

As Senior Managers, NHS GG&C Directors play an intrinsic role in ensuring that water safety is embedded within the culture of the organisation.

The responsibilities of Directors include:

- Supporting the Designated Persons (Water) and (Pseudomonas) in the development of the Board's overall strategy in relation to water safety and for ensuring implementation within their areas of responsibility;
- Ensuring that all staff are made aware of their requirement to attend Water Safety training at the appropriate frequency, as per the NHS GG&C Water Safety Policy and Operational Procedures which underpin this by facilitating staff release from duties to attend training;
- Support action to address staff who put themselves and/or others at risk from a real or potential water safety incident;

3.10 Heads of Service, Departmental Managers, Clinical Managers, Senior Charge Nurse's

All managers who have a responsibility for the day to day management of facilities, staff or services, and/or premises, have water safety responsibilities that include:

- Familiarise themselves with the NHS GG&C Water Safety Policy and local control measures including any water risk assessments for their area(s) of responsibility;
- Ensuring that persons in the department, clinic or ward are fully aware of their responsibilities and duties in respect of Water Safety, in particular, the

action required of them should the area be defined as High Risk by the local Water Safety Group

- Ensure that persons in the department, clinic or ward are fully aware of the 'Infrequently Used Outlets' definitions and Operating Procedure which underpins the NHSGG&C Water Safety Policy
- Actively promoting Water Safety within the department or ward by maintaining good housekeeping within the department or ward at all times, ensuring that any flushing or documentation as described in the Water Safety Written Scheme and Operational Procedures documentation is completed on time
- Responding appropriately to any water safety concerns that persons in the department, clinic or ward have;
- Nominating a responsible person to complete the Monthly 'Infrequently Used Outlets' Audit for each area, forwarding a copy to the Site Maintenance/Estates Manager, thereby assisting NHSGG&C to meet its statutory and mandatory requirements;
- Ensuring that action is taken on a daily basis to address any access issues identified within the Cleaning Compliance Checklist Sign Off documentation retained in the Facilities Folder.
- Liaising with the estates department as required

4.0 Governance Structure

The governance arrangements described above shall be put in place within NHSGG&C.

The responsibilities of the **Corporate Management Team** include:

- Implementing the Boards overall Water Systems Safety Policy including legislative compliance.
- Liaising with the Infection Control Manager (Designated Person (Pseudomonas)) and the Director of Property, Procurement and Facilities Management (Designated Person (Water)) to ensure the Boards Water Systems Policy is understood and applied across all areas of the Board.
- Formulating with the Infection Control Manager and Director of Property, Procurement and Facilities Management a Water Systems safety compliance programme for both passive and active measures in both existing building and new projects.

- Performing governance responsibility for reviewing operational arrangements effectiveness. The Corporate Management Team will be advised on this by the Boards Infection Control Committee (BICC) with contributions from the Infection Control Manager (Designated Person (Pseudomonas)) and the Director of Property, Procurement and Facilities Management (Designated Person (Water)) via the Board Water Systems Safety Group

5.0 Risk Reduction Strategy / Procedures

Following any assessment of the risk, risk reduction strategies and procedures must be implemented where possible to reduce the likelihood and/or severity of incidents from infection

Risk Reduction strategies/procedures include:

- Policy awareness and implementation;
- Risk assessment both generic and specific;
- Training;
- Local procedure development;
- Reporting and recording;
- Evaluating effectiveness of risk reduction strategies/procedures;
- Reviewing in the light of experience; look at incident investigation and inspection reports. Do they show improvement?
- Re-train staff if required, reading available policies, strategies and procedures;
- Review clinical and workplace risk assessments after reports of any adverse events;
- Implementation of risk reduction strategies as defined by the findings of the risk assessment for the NHSGGC buildings;
- Implementation of a formal review/audit process of the risk reduction procedures;
- Implementation of contractor audit and review procedures.

Sector Water Safety Groups are responsible for ensuring that a multi disciplinary approach is taken to Risk Reduction within the Board at local level.

6.0 Operational Arrangements

Water systems throughout NHSGG&C are subject to a routine planned maintenance system. NHSGG&C shall have in place a site specific Written Scheme and Operational Procedure for Water System Safety

The written scheme and Operational procedure for Water System safety shall be followed for the management of water systems for the prevention of infection

7.0 Testing for Legionella

In keeping with the current HSE guidance, testing for legionella will be carried out within NHSGG&C as follows:-

Clinical Risk Areas;

- It has been agreed with the NHS GG&C Lead Infection Control Doctor that the following area is a 'high-risk clinical area' where immune-compromised patients are present;
 - Transplant units.

The 'clinical high risk areas' will be specifically identified within the site specific 'written scheme';

Engineering Risk Areas;

Due to the 'age' of the current building stock within NHS GG&C it is recognised that there are areas where a 'high-risk' is present due to current water distribution configuration and as such testing will be required. The 'engineering risk areas' are as follows:

- In water systems treated with biocides where water is stored or distribution temperatures are reduced;
- In water systems where the control levels of the treatment regime, eg temperature or disinfectant concentrations, are not being consistently achieved;
- In water systems suspected or identified in a case or outbreak of legionellosis where it is probable the Incident Control Team will require samples to be taken for analysis;
- In areas which have been identified within the current Water Safety Risk Assessment as being of a risk.

The 'engineering high risk areas' will be specifically identified within the site specific 'written scheme'.

8.0 Pseudomonas

NHS GG&C complies with the HFS, HPS and *Pseudomonas aeruginosa* and Water (Scotland) Group guidance document titled '*Guidance for neonatal units (NNUs) (levels 1, 2 & 3), adult and paediatric intensive care units (ICUs) in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water*' version 2 dated July 2014.

9.0 Reporting and Monitoring

If, following a legionella water sample, a reading of legionella bacteria is shown to be present and, following the criteria that the usual control measures to eliminate this legionella bacteria have been undertaken, that should the follow-up reading still record that legionella bacteria is present, then a record of this incident will be made on NHS GG&C's Datix reporting and recording system in line with the NHS GG&C's

Incident Management Policy and Procedure. The Facilities Directorate must be copied into all Datix reported incidents.

Line managers must ensure that a review and investigation of an infection incident which can be demonstrated as originating in a water system is carried out and recorded.

They should be reviewed as a significant adverse event as per the Incident Management Policy and Procedure.

In order to ensure the implementation and effectiveness of this policy all incident reports relating to water management should be reviewed regularly by the responsible manager via the Sector Water Safety Group.

10.0 Audit

The application and effectiveness of this policy throughout the organisation shall be monitored by the Health and Safety Department reporting via the Board Water Safety Group and the Estates Senior Management Team (SMT).

The policy will be reviewed and revised on a regular basis or as a result of changes in legislation and national guidance.

11.0 Guidance

The following references form a compendium of literature available at the present time to which reference should be made –

- Health & Safety at Work, etc. Act 1974

1.0 GENERAL OVERVIEW

Note 1: No work will be carried out on the water system without the knowledge and written consent of the Authorised Person (Water).

Note 2: This Written Scheme document is to be read in conjunction with the Operational Procedures for the Written Schemes document and should also be read in conjunction with the Control of Water Records document. For any alterations to the Water System this Written Scheme Document is to be read in conjunction with the Guidance for alterations to water systems document.

1.1 Introduction

This document contains six sections which have been derived from the Risk Assessment to aid the design, installation, maintenance and operational mode of all domestic and process water systems within the premises with respect to the likelihood of the proliferation of waterborne micro-organisms. The assessment also considered the risk of infection presented to building users and the general populous at large, and derived a series of risk ratings and appropriate Remedial Actions and Control Measures, which should be implemented to minimise the presented risks. This Risk Assessment was carried out in a manner consistent with the requirements of *BS8580:2010 Water Quality – Risk Assessments for Legionella Control – Code of Practice*, and is reviewed whenever system alterations or operational considerations may effect a change in the risk.

Section 1 contains an Executive Summary of the recommended control measures and corrective actions together with an overview of the QUEH Site layout and accommodation.

Section 2 contains a record of the logbook inspection, details on the location of records, defects, non-compliance issues, correspondence and archived information.

Section 3 provides information on the management structure associated with the control scheme for the water system and clear definitions of responsibilities held by those named, details of training undertaken and a summary of the designated tasks as detailed in section 4.

This section also provides information on the details of the risk assessment values associated with representative outlets, systems and plant items undertaken since 2013. A generic risk assessment for any positive legionella test results within designated Low Risk locations and a description of the installed plant and equipment with associated schematic layout plans for each of the installed water systems within the site is also contained within this section.

Section 4 of the document details the safe operation of the system and all appropriate Maintenance Procedures (Control Measures) which were derived from the Risk Assessment and recommendations within NHS Greater Glasgow and Clyde Water Systems Safety Policy.

This section of the document contains a task description with associated record (Log) sheet relating to these activities. It should be noted however, that in certain circumstances, specialist contractors are required to implement some Control Measures, and records pertaining to these activities may be held under separate cover. Such activities would typically include those associated with chemical water treatment regimes and drinks vending machines sanitising maintenance.

Refer to Section 2 for the location of records and archived information associated with the maintenance procedures and other control measures.

Section 5 contains supporting information relating to the Control Scheme, and should typically include the recording of system alterations or remedial actions together with utilised materials. Ad hoc maintenance activities should also be recorded in this section, such as system sterilisations which may be required from time to time. This section of the document also contains a glossary of supporting publications, where additional information relating to the risks associated with waterborne micro-organisms, and water quality generally, may be found.

1.2 Executive Summary

The purpose of this Written Scheme document is to assist in the correct and safe operation of the water systems within the QEUH Campus. The document outlines the specific roles, responsibilities, training requirements and regular maintenance procedures to be followed in order to ensure compliance with statutory and mandatory guidance.

Risk Assessments for the water services have been carried out on the instruction of the Board Water Safety Group. DMA Canyon Ltd are presently the appointed Water Systems Risk Assessor and have carried out Risk Assessments within all individual buildings on the campus.

Additionally there are two Hydrotherapy Pools in operation on the campus. These are situated within the New Childrens Hospital, and Spinal Injuries Unit. Separate Risk Assessments have been carried out for both of these facilities by a specialist Swimming Pool Risk Assessment provider.

Risk Assessments require to be reviewed and updated to reflect any changes in-use and / or functions that have taken place since the date of the original Risk Assessment or in the event of control measures becoming ineffective, changes in key personnel or in the event of a case of legionnaires disease / legionellosis associated with the water system. Guidance on the Risk Assessment review procedure is given in Appendix 3.

All documentation and log sheets used to record maintenance activities follow the format contained within guidance document SHTM 04-01 Part G: *Operational Procedures and Exemplar Written Scheme*.

1.3 Overview of Site Accommodation and Premises

The main new-build Adult Hospital building comprises of 12 stories, with the basement housing FM areas and the new-build Childrens Hospital comprising of 4 stories.

On the retained estate there are individual buildings comprising of Neurology, Neurosurgery, Spinal Injuries Unit, PDRU, Maternity, Neo-Natal, Podiatry and Westmarc stand alone with the Teaching and learning and office block new additions.

Full descriptions and information on the individual written schemes are available in the Log book/Risk Assessment folders for each building.

The building codes are as follows:

AQ – Acute Medical Block (AMB)
AS – Central Medical Block (CMB)
BC – Neurosurgical Block (INS)
BL – Maternity
BW – Neurology
DA – Spinal Injuries
DB – Maternity Day Surgery
DD – Podiatry
DE – Physically Disabled Rehabilitation Unit (PDRU)
DI – WestMARC
EA – Neo Natal
FA – Multi Storey Car Park 2
FB – Multi Storey Car Park 1
GA – Laboratory Medicine
GB – Energy Centre
HA – Adults Hospital
HB – Childrens Hospital
IA – Teaching & Learning Centre
IB – Office Building
IC – Imaging Centre of Excellence (ICE)

NOTE: ICE building is owned by University of Glasgow. Facilities management and maintenance is carried out under contract by NHS GG&C on behalf of UoG.

See Site Map in Appendix 1

2.0 RECORDING

2.1 Written Scheme Inspection Records

Anyone inspecting this written scheme (either as part of the Management Control System or otherwise) is invited to make an entry in this inspection record. **Under no circumstances may this Written Scheme or any part of it be removed from site.**

Date/Time	Comments	Signature	Position
June 2018	Written scheme has been reviewed and re-formatted into this current form (Revision D) by Colin Purdon as part of the water systems review.		Site Manager Operational Estates
Feb 2019	Written scheme has been reviewed and re-formatted into this current form (Revision E) by Colin Purdon as part of the water systems review.		Interim Sector Estates Manager (Deputy Responsible Person)
May 2019	Written scheme has been reviewed and re-formatted into this current form (2019 Rev A) by Colin Purdon as part of the water systems review.		Interim Sector Estates Manager (Deputy Responsible Person)

Additional entries should be completed on a separate sheet and inserted in Section 2.1 with this sheet.

2.2 Location of Records and Correspondence

Details of any correspondence, including Risk Assessments/Reviews and Ongoing Monitoring Reports, relating to water services should be entered on the sheet below, recording where held and by whom.

Date	Procedure or Record ref	Description	Held by/location
16/07/18	Flushing Outlets 026	Email correspondence in relation to Flushing DCFP kitchen dishwasher and outlets with John Heron and Adam Wright	Colin Purdon email archive. Hard copy in correspondence logbook

Additional entries should be completed on a separate sheet and inserted in Section 2.2 with this sheet.

2.3 Non-Compliance Issues and Fault Detail Log

Record Form 004

All non-compliance and fault details in relation to the individual systems in each building must be recorded on Record Form 004 and brought to the attention of the Water Systems Lead AP as soon as possible. This process ensures that all non-compliance issues are documented, managed effectively and tracked through to completion and close –out of the issue. Copies of the all Record Form 004 are to be stored locally within the Estates Management office.

2.4 Archived Information Record Sheet

All records associated with the management or maintenance procedures within this Written Scheme should be kept for a period of five years after they are no longer current. Records should be kept locally within the main Estates Office. The details of any archived information held separately in secure storage should be recorded in the table below.

Date	Procedure or Record Reference	Description	Held By/Location

Additional entries should be completed on a separate sheet and inserted in Section 2.4

2.5 Equipment Calibration Records

All equipment used for the measurement of temperatures should be calibrated at least annually to ensure the accuracy and consistency of the recording procedures.

Calibration certificates for handheld thermometers are held in hard copy within the QEUEH Campus Log Book suite in the main estates office. Electronic copies are also held on the QEUEH Shared Drive>Water Quality folder.

3.0 MANAGEMENT ARRANGEMENTS

3.1 Roles & Responsibilities

NHS Greater Glasgow & Clyde Chief Executive – (Duty Holder)	The Chief Executive has ultimate responsibility / accountability for water system safety within NHSGG&C. The responsibilities of the Chief Executive include: • Responsibility for implementation of the relevant mandatory and statutory elements contained within the Health & Safety Commissions Approved Code of Practice and Guidance “Legionnaires Disease. The control of Legionella bacteria in water systems” L8 (ACOP L8), SHTM04-01: The control of Legionella, hygiene safe” hot water, cold water and drinking water systems and CEL 08(2013) water sources and potential risk to patients in high risk units – revised guidance. The implementation of Guidance for neonatal units (NNU’s) (levels 1, 2 & 3) adult and paediatric intensive care units ICU’s in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water. • Ensuring that adequate resources are provided to meet the Water Systems Safety requirements of NHSGG&C estate. Ensuring that the Water Systems Safety Policy is being implemented at all levels. • Reviewing and monitoring the operation of the Water Systems Safety Policy through the Board Corporate Management Team and ensuring that clear guidelines are provided for this tasked with compliance of legislative and statutory standards. • Appointing the Designated person (Pseudomonas) and Designated Person (Water) to assist in the execution of these responsibilities, who for NHSGG&C are the Infection Control Manager (Pseudomonas) and the Director of Facilities (Water).
NHS Greater Glasgow and Clyde Director of Facilities- (Designated Person)	The Director of Facilities/General Manager (Estates) is the Designated Person (Water). They shall be responsible for: • Ensuring that Facilities staff, through the general management structure is fully aware of the current statutory and mandatory requirements and standards for the provision and maintenance of safe water systems. • Ensuring with the Responsible Person (Pseudomonas) that the Water System Safety Policy is regularly reviewed and updated. • Co-Chair the NHSGG&C Water Systems Safety Group. • Appointing in writing the Responsible Person (Water) at sector level and Deputy Responsible Person(s) (Water) at site level. This shall be the Sector Estates Manager (SEM) and the relevant Site Manager Operational Estates (SMOE)/Site Estates Manager within the Facilities Directorate management structure.

3.1 Roles and Responsibilities (cont)

NHS Greater Glasgow and Clyde Infection Control Manager - Designated Person (Pseudomonas)	The Infection Control Manager supported by the Board Infection Control Doctor is the Responsible Person (Pseudomonas). They shall be responsible for: • Ensuring that Infection Control Teams are fully aware of current guidance on Legionella control matters and the minimisation of the risk of Pseudomonas aeruginosa infection from water. • The implementation of Guidance for neonatal units (NNU's) (levels 1, 2 & 3) adult and paediatric intensive care units ICU's in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water. • Ensuring with the Designated Person (Water) that the Water System Safety Policy is regularly reviewed and updated. • Co-Chair the NHSGG&C Water Systems Safety Group. • Appointing in writing the Responsible Person(s) (Pseudomonas) at sector level. This shall be the relevant Infection Control Doctor.
Sector Estates Manager – Responsible Person (Water)	The Sector Estates Manager will be appointed as the Responsible Person (Water) at Sector level by the Director of Facilities/General manager (Estates) in writing. The Sector Estates Manager is responsible for: • Ensuring the effective maintenance of engineering controls installed for the purposes of controlling water systems. • Ensuring that written schemes and risk assessments are in place and reviewed regularly. • Devising and maintaining procedures to ensure the quality of water on premises is maintained. • Ensuring operational procedures are carried out and documented. • Ensuring records are kept of all water systems and their purpose, giving locations recording and maintaining within the Boards estates management system. • Liaise closely with other professionals to ensure legislative and statutory compliance is maintained by the Board.
Authorising Engineer (AE)	An Authorising Engineer acts as an independent professional advisor to the healthcare organisation, appointed by the organisation with a brief to provide services in accordance with Scottish Health Technical Memorandum (SHTM) guidance. He will be appointed in writing by the Director of Facilities/General manager (Estates). The Authorising Engineer acts as an assessor, making recommendations for the appointment of Authorised Persons, monitoring the performance of the service and providing an annual audit to the organisation's Designated Person.

3.1 Roles and Responsibilities (cont)

Authorised Person (Water)	The Authorised Person (water) has the key operational responsibility for the service, qualified, sufficiently experienced and skilled for the purpose. He/she will be nominated by the Authorising Engineer and be able to demonstrate • His/her application through familiarization with the system and attendance at an appropriate professional course; • A level of experience; • Evidence of knowledge and skills. An important element of the Authorised Person (Water) role is the maintenance of records, quality of service and maintenance of system safety (integrity). The Authorised Person (Water) will also be responsible for establishing and maintaining the roles and validation of Competent Persons (Water) who shall be suitable trained employees of the organisation or appointed contractors. Larger sites may require more than one Authorised Person (Water) for a particular service. The Authorised Person (Water) will be appointed by the Director of facilities/General Manager (Estates).
Head of Capital Planning – Deputy Responsible Person (Water)	The Head of Capital Planning will be appointed as the Deputy Responsible Person (Water) at Board level by the Director of Facilities/General Manager (Estates) in writing. The Head of Capital Planning is responsible for: • Ensuring that any new works undertaken or refurbishment within existing premises shall comply with the requirements of this Policy and the Written Scheme and Operational Procedure for managing Water Safety including The control of <i>Legionella</i>, hygiene, ‘safe’ hot water, cold water and drinking Water systems and The implementation of Guidance for neonatal units (NNU’s) (levels 1, 2 & 3) adult and paediatric intensive care units ICU’s in Scotland to minimise the risk of <i>Pseudomonas aeruginosa</i> infection from water. • Ensuring that all potential interfaces between an operating system and new and refurbishment works shall meet the approval of the Responsible Person (Water) and Authorised Person (water) as to methodology for making that interface. • Ensuring that any work involving the installation of water services or equipment requiring a water supply shall follow the guidance in SHTM 04-01 and HSE document L8 and shall be certified by the design Engineer as to that compliance. • Ensuring that any works which will affect an operational water service will be discussed with the Estates Authorised Person (Water) prior to arranging that work.

3.1 Roles and Responsibilities (cont)

Site Estates Manager Deputy Responsible Person (Water)	The Site Manager Operational Estates (SMOE)/Site Estates Manager shall be appointed in writing by the Director of Facilities/General Manager (Estates) in writing as the Deputy Responsible Person (Water) and will also act as the Designated Person Water in the absence of the Designated Person (Water). The Site Maintenance Manager/Site Estates Manager is responsible for: • Ensuring all staff conducting water system maintenance are competent to do so. • Ensuring water system maintenance records are maintained and kept up-to-date. • Regularly checking maintenance records. • Ensuring all work is completed in accordance with the NHS GG&C Estates Procedures.
Acute Services Directors CH(C)P Directors and Corporate Division Directors	As Senior Managers, NHSGG&C Directors play an intrinsic role in ensuring that water safety is embedded within the culture of the organisation. The responsibilities of Directors include: • Supporting the designated person (Water) and (Pseudomonas) in the development of the Board's overall strategy in relation to water safety and for ensuring implementation within their areas of responsibility; • Ensuring that all staff are made aware of their requirement to attend Water Safety training at the appropriate frequency, as per the NHSGG&C Water Safety Policy and Operational Procedures which underpin this by facilitating staff release from duties to attend training; • Supporting action to address staff who put themselves and/or others at risk from a real or potential water safety incident.
Heads of Service, Departmental Managers, Clinical Managers, Senior Charge Nurse's	All managers who have a responsibility for the day to day management of facilities, staff or services, and/or premises, have water safety responsibilities that include: • Familiarise themselves with the NHSGG&C Water Safety Policy and local control measures including any water risk assessments for their area(s) of responsibility; • Ensuring that persons in the department, clinic or ward are fully aware of their responsibilities and duties in respect of Water Safety, in particular, the action required of them should the area be defined as High Risk by the local Water Safety Group • Ensure that persons in the department, clinic or ward are fully aware of the Infrequently Used Outlets definitions and Operating Procedure which underpins the NHSGG&C Water Safety Policy

3.1 Roles and Responsibilities (cont)

Heads of Service, Departmental Managers, Clinical Managers, Senior Charge Nurse's (cont)	• Actively promoting Water Safety within the department or ward by maintaining good housekeeping within the department or ward at all times, ensuring that any flushing or documentation as described in the Water Safety Written Scheme and Operational Procedures documentation is completed on time • Responding appropriately to any water safety concerns that persons in the department, clinic or ward have; • Nominating a responsible person to complete the Monthly Infrequently Used Outlets Audit for each area, forwarding a copy to the Site Maintenance Manager, thereby assisting NHSGG&C to meet its statutory and mandatory requirements; • Ensuring that action is taken on a daily basis to address any access issues identified within the Cleaning Compliance Checklist Sign Off documentation retained in the Facilities Folder. • Liaising with the estates department as required
Legionella Risk Assessor	The NHS Board appoints in writing a Legionella Risk Assessor with terms of reference to provide services in accordance with BS 8580, SHTM 04-01 and HSE guidance under this Policy. He/she will be appointed in writing by the Director of Facilities/General Manager (Estates)
Competent Person (Water)	The Competent Person (Water) provides skilled installation and/or maintenance of the specialist service. He/she will be appointed, or authorised to work (if a contractor) by the Authorised Person Water). He/she will demonstrate a sound trade background and specific skill in the specialist service, working under the direction of the Authorised Person (Water) in accordance with operating procedures, policies and standards of the service.
Maintenance Tradesperson	A Maintenance Tradesperson is someone who has sufficient technical knowledge and the experience necessary to carry out maintenance and routine testing of the water supply, storage and distribution system.
Installer	The Installer is the person or organisation responsible for the provision of the water storage and distribution system.
Contractor	A Contractor is the person or organisation designated by management to be responsible for the supply, installation, validation and verification of hot and cold water services, and for the conduct of the installation checks and tests in relation to the control of <i>Legionella</i>. The NHS Board will expect potential contractors to have suitable qualifications (for example companies/individuals who are members of the <i>Legionella</i> Control Association).

3.1 Roles and Responsibilities (cont)

NHS GG&C South Sector (QEUH) Hierarchy Appointment Table

Designation	Position	Name Tel Number
The Duty Holder	Chief Executive	Jane Grant
Designated Person (Water)	Director of Facilities/General Manager (Estates)	Alan Gallacher Mary-Anne Kane
Authorising Engineer (Water)	Legionella Control International Ltd	Dennis Kelly [REDACTED]
Legionella Risk Assessor	DMA Water Services Ltd	David Watson Mike Kinghorn Allan McRobbie [REDACTED]
Responsible Person (Water)	Sector Estates Manger (South)	Colin Purdon (Interim) TBC in writing
Deputy Responsible Person (Water)	Site Manager Operational Estates (Building)	VACANT
Deputy Responsible Person (Water)	General Manager Capital Planning	Hazel McIntyre [REDACTED]
Lead Authorised Person	Estates Manager	Mel MacMillan
Authorised Persons	Estates Manager Co-ordinating Supervisor Co-ordinating Supervisor Co-ordinating Supervisor	Kerr Clarkson Scott Macer Darren Hopkins Frank Green
Competent Persons	CAD Technician	Bernard McCulloch
Competent Persons	Plumbers/Engineers	See training records in Section 3.4
Others Involved		
Infection Control	Lead Microbiologist	Dr Teresa Inkster
Public Health		Dr Iain Kennedy
Laboratory Services		Janet Young

3.2 QEUH Estates Staffing

Management organogram for QEUH Estates Dept as of Oct 2019

3.3 Required Maintenance Tasks

The maintenance and management of the water systems throughout the QEUH Campus is undertaken by a combination of both NHS Staff and external Contractors at the frequencies identified in the following tables.

QEUH Management staff manage and oversee the following tasks:

Procedure Reference	Operation(s)	Record Form Ref	Frequency
P1C1	BMS Temperature Monitoring	(004)	Daily
P1CC1A	Manual Temperature Monitoring	(005a)	Daily
N/A	Filtration Plant Checks		Twice Daily
WS01	Flushing Intermittently used outlets	(026)	Twice Weekly
WS01	Flushing Deadlegs and drain cocks	(026)	Twice Weekly
WS01	Deluge shower/Eye wash flushing	(026)	Twice Weekly
P1C3	Pump operation/duty rotation	(028)	Weekly
P1C4	Temperature Recording of Sentinel Hot and Cold Water Outlets.	(005)	Monthly
P1C4	DHW Calorifier and Buffer Vessel Checks	(005)	Monthly
P1C12	Showerhead/hose replacement/disinfection	(005b)	Quarterly
P1C6	DWS Calorifier, Expansion Vessel Flushing	(006) (023)	Quarterly
WQS 001	HORNE Tap Flow Restrictor Exchange		Quarterly
WS01	Review of Rarely Used Water Outlets and Changes In-Use		Quarterly
N/A	TMV/TMT & Thermostatic Shower Disinfection and Function Test (HIGH RISK)		Quarterly
N/A	TMV/TMT & Thermostatic Shower Disinfection and Function Test (Non-HIGH RISK)		Six-Monthly
P1C7	CWST Inspection and Temperature Monitoring	(003)	Six-Monthly
P1C9	DWS Calorifier / Expansion Vessel Inspection	(006)	Annually
N/A	Water Services Pipework and Distribution System Checks		Annually
P1C10	Representative Tap Temperature Monitoring	(005)	Annually
N/A	Vibration coupling inspection		Annually
N/A	Carry out review of log books and Written Scheme		Annually (Sep)
N/A	Carry out review of drawings and schematics		Annually (Sep)

3.3 Required Maintenance Tasks (cont)

In addition to the tasks undertaken by NHS directly employed Competent Persons, there are also tasks undertaken by Contractors on a selection of buildings within the campus.

Appointed Contractors presently undertake the following tasks:

Procedure Reference	Operation(s)	Record Form Ref	Frequency
	External Water Mains Valve Operation and Flushing Routines		Monthly
	'TMV' and Mixing Valve Sanitation and Maintenance Checks		Three-Monthly
	Shower Head and Flexible Hose Exchange		Three-Monthly
	'TMV' Tap Outlet Sanitisation and Operational Checks		Six-Monthly
	CWST Inspection	(003a)	Annually
	Hot and Cold Tap Outlet Sanitisation and Operational Checks		Annually

3.4 Training Records

The following NHS personnel are certified to have the required ability, experience, instruction, information and training to carry out the work associated with legionella precautions at QEUH Campus.

NAME	POSITION	NATURE OF TRAINING (QUALIFICATION, TRAINING COURSES ATTENDED)	DATE
Colin Purdon	<i>Interim</i> Sector Estates Manager Deputy RP	Responsible Person Course ENAP City & Guilds Authorised Person ENWS City & Guilds Managing Water Systems	
Mel MacMillan	Estates Manager Lead AP	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	
Kerr Clarkson	Estates Manager AP	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	
Scott Macer	Co-Ordinating Supervisor (Shifts)	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	
Darren Hopkins	Co-Ordinating Supervisor AP	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	
Frank Green	Estates Manager	WHH01 – Legionella Management for Water Systems SHTM-04 01 WH003 - Legionella Control Within Hot and Cold Water Systems	

Copies of all relevant training records and appointment letters are held electronically on the QEUH Shared Drive within the folder path “Water Quality>Training and Appointments”.

The results achieved by each member of staff during their competency training are held on the central database managed by the Water Systems Compliance Manager.

NAME	POSITION	NATURE OF TRAINING (QUALIFICATION, TRAINING COURSES ATTENDED)	DATE
Martin Inglis	Tech Plumber	Competent Persons	
Andrew Hamilton	Tech Plumber	Competent Persons	
David Fickling	Tech Plumber	Competent Persons	
Peter McCabe	Tech Plumber	Competent Persons	
Mark McNally	Tech Plumber	Competent Persons	
Shawn O'Neill	Tech Plumber	Competent Persons	
Jason Weir	Tech Plumber	Competent Persons	
Paul Shorts	Tech Plumber	Competent Persons	
Bernie McCulloch	CAD Technician	Competent Persons	

Copies of all relevant training records and appointment letters are held electronically on the QEUH Shared Drive within the folder path “Water Quality>Training and Appointments”.

The results achieved by each member of staff during their competency training are held on the central database managed by the Water Systems Compliance Manager.

3.5 Training Requirements

A programme of training and procedures to assist in assessing and ensuring the competence of ALL persons responsible for the operation, maintenance, repair and alteration to the water distribution system and associated plant and equipment requires to be progressed, developed and implemented.

QEUH Estates Staff - Interim Training Requirements:

Item	Training Requirement	Applicable to	Target Date for Completion	Date Completed
1	Toolbox talks on Written Scheme Section 4 for staff.	All plumbers		
2				
3				
4				
5				
6				
7				
8				
9				
10				
11				
12				

NOTE:- This table should be updated on a regular basis as part of the review process described in **Section 3.10.**

3.6 Water Systems Risk Assessment

The duly appointed *Legionella* Risk Assessor for *Legionella* and Water Systems Safety will update the *Legionella* risk assessment database as directed by the board.

Risk assessments for each building have been conducted by DMA Water Ltd and are filed in the main Estates Office at QEUEH. Each contains details of individual systems and a summary of the associated risks. The risk assessments each contain unique information in regard to the water distribution systems in the buildings and also guidance on the recommended maintenance procedures for mitigating risk.

Risk Assessment Review-Escalations

During the Risk Assessment, whenever an anomaly is discovered on either the hot or cold water systems, the Risk Assessors e-mail the AP (water) with their findings. These anomalies are actioned by creating a FM job for the onsite CP Plumbing Technician. The findings are held in the Estates office in the folder named (Pre Risk Assessment Jobs completed).

Risk Assessment Process for Removal of Identified Items

Points are actioned that have been identified in the Risk Assessment, all drawings are updated to reflect the changes and the Risk Assessment action point is closed.

Risk Assessment Review Schedule

A review of the Risk Assessments MUST be carried out after or during the following:

A change to the water system or its use

A change to the use of the building/ward/clinic/dept etc.

Changes in legislation or updates in control measures

Changes in immediate management or key personnel

Control measures becoming ineffective

Increased micro-bacterial levels found in the water system or a case of legionnaires disease/legionellosis associated with the water system.

Action plan details for each risk assessment are summarised on the Smartsheet tool.

Electronic copies of the Risk Assessments are also held on the QEUEH Shared Drive at the folder path

“Water Quality>Risk Assessments”

Further information on reviewing Risk Assessments is detailed in Appendix 3.

3.7 Plant Description and Schematics

Details of the plant in each building and schematic layouts are contained within the individual log books/risk assessments for each building. The log books/risk assessments are stored in the main Estates Office at QEUH.

These details are also held on the Shared Drive

All plant details and system schematics and as-fitted drawings for the Adult & Childrens Hospitals are contained in the ZUTEC cloud based document management system. All Estates Managers and Supervisors have access to these systems.

Additional access accounts can be set up at the request of the QEUH Site Manager Operational Estates.

[Brendan.egan](#) [REDACTED]

3.8 Water Systems Audits/Review Procedures

A duly appointed Authorising Engineer (Water) will audit the entire Water Safety procedures within *NHS Board* annually.

The appointed Authorising Engineer for Water Safety will produce an annual report for management review. *See Section 3.1 pg 18 for current appointments.*

AE Audit

The Lead Authorised Person (Water) must regularly gather and maintain all the relevant information and records, including relevant Water Safety Risk Assessments and Written Schemes.

Working with the Authorising Engineer (Water) and Responsible Person (Water), the relevant Authorised Person (Water) will review and analyse all records for compliance with *Legionella* and other water safety parameters.

The relevant Authorised Person (Water) will detail on these records any deviations from the *Legionella* and other water safety parameters giving a brief description as to the reason for this deviation.

The Audit Programme will consist of planned audits on the following elements, for example:

Risk Assessments;

All documentation associated with this Written Scheme

training review and records;

schematic drawings;

Water Safety Log Books/Maintenance records;

BMS trend log comparison.

A report will be produced summarising the audit for submission to the Sector Water Safety Group.

The Lead Authorised Person (Water) will file locally, all relevant information and maintain hard copy records in the Water Safety Log Books stored within the main Estates Office. All actions identified should be tracked to ensure completion and closure.

Summary of Internal/External Audit Procedures

Frequency	Task	By Whom
Annually	Carry out Authorising Engineers Audit and produce report for submission to Sector Water Safety Group (Section 3.8 WS)	Lead AP, AE,
Annually/May	Carry out annual review of written scheme and produce report for submission to Sector Water Safety Group (Section 3.9 WS)	RP/DRP, Lead AP, Compliance Mgr
6 monthly	Carry out management review (Section 3.10 WS)	RP/DRP, Lead AP, Compliance Mgr
Monthly	Carry out regular audit of SCART topic and update database (Section 3.11 WS)	Lead AP
Monthly	Conduct contractor meetings/audits to ensure compliance with legislation and training requirements.(Section 3.12 WS)	Lead AP

3.9 Written Scheme Audit Procedure

The Written Scheme will be audited at agreed intervals but should be at least annually.

An audit schedule will be prepared to ensure the entire procedure is audited. This should be done in conjunction with the Lead AP (Water Systems), Compliance manager, and Responsible Person (Water Systems). A report should be produced and submitted to the Sector Water Safety Group.

3.10 Management Review

The Responsible Person (Water) will hold regular review meetings to confirm current compliance with Water Safety System requirements, identification of any deficiencies and actions required to resolve staff training needs.

The management review will be based on following:

results of internal audits;

results of external audits;

staff suggestions;

training records;

operation of the system and procedures over a reasonable historic period (6 to 12 months)

3.11 Water Systems SCART Report

The Lead Authorised Person (Water) must regularly gather and maintain all the relevant information for import into the Campus SCART system.

All evidence confirming the SCART position and justification for risk rating adjustments should be uploaded to the SCART database in electronic format.

3.12 Contractor Management & Audit Report

Contractor Management Process

Regular review meetings should be set up with any contractors working on the water distribution system. Minutes of the meetings are held on the QEUH Estates Shared Drive at the path: SGH Estates>Water Quality>Contractor Meetings.

Discussions should include:

- Ongoing works;
- Future task programme;
- Recording procedures;
- RAMS;

Contractor Competency

Regular checks should be performed to ensure that any contractors working on the water distribution system are deemed competent and all operatives are suitably trained to conduct the delegated tasks. Copies of all Risk Assessments and Method Statements should be refreshed and all training records reviewed by the Water Systems AP. Copies are stored on the QEUH Campus Shared Drive in Water Quality.

Contractor Audit Report

A report should be produced at least annually to record the findings of the audit.

3.13 Permit to Work, Water Systems.

The Permit to Work Water Systems as per this written scheme is solely intended to be used when works on the hot and cold water systems and its ancillary equipment are to be completed within the QEUH and RHC campus. This includes break-ins to existing pipe work, removal of dead legs and any new installation works.

The Permit to Work may only be issued to Competent Persons (L8 approved) by the Authorised Person (AP) for water. This includes in house maintenance staff and approved contractors.

The Permit to Work form will include the following;

- Name of the organisation issuing the permit.
- Permit number.
- Name of Authorising Person (AP), including emergency contact details.
- Reasons for the works on the water system, (Plant Preventive Maintenance, Planned repairs or Emergency works).
- Exact location of the works
- Reference to any as built drawing numbers, (for update purposes).
- Name of Competent Person (CP) undertaking the works.
- Hazards and Risks, (copy of Risk assessment and Method Statements (RAMS) to be submitted for approval before start of works)
- Commissioning and Testing.

The above points on the Permit Work are broken into five categories, namely;

Part 1 Description of work and authorisation/permission to proceed.

Part 2 CP acceptance of work and conditions.

Part 3 Confirmation of work completion and engineering test results.

Part 4 Authorisation to use a system.

Part 5 Acceptance of system status by Nurse Manager.

Procedure to be followed for Permit to Work on water systems within the QEUH and RHC;

Sign into Estates office within the Laboratory building on the QEUH and RHC campus.

Receive induction from Authorised Person water.

Provide L8 Competent Person certification to Authorised Person water.

Provide applicable RAMS for the works to be completed.

3.14 Tool Box Talk, Hot and Cold Water Systems.

Estates Tool Box Talk on Hot and Cold water Systems is located on the shared drive / water quality / Estates Tool Talk. This is carried out in the form of a power point presentation.

4.0 MAINTENANCE PROCEDURES

Procedure Reference	Operation
4.1	SYSTEM INFORMATION
4.2	MAINTENANCE PROCEDURES SUMMARY
4.3	WEEKLY MAINTENANCE TASKS
4.4	MONTHLY MAINTENANCE TASKS
4.5	QUARTERLY MAINTENANCE TASKS
4.6	SIX MONTHLY MAINTENANCE TASKS
4.7	ANNUAL MAINTENANCE TASKS
4.9	BI-ANNUAL MAINTENANCE TASKS

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.1 System Information

4.1.1 Correct and Safe Operation of the System

Measures should be in place to ensure that the water system is operated within the specific parameters as detailed in the following paragraphs:

4.1.2 Hot Water System

The storage of domestic hot water should be arranged to ensure that a water outflow temperature of at least 60°C is achieved. No two water systems are the same and through periodic monitoring operational system performance, the system outflow temperature should be set to over 60°C to ensure an outflow of 60°C is achieved under normal draw-off demand and achieve 55°C at the supply to the furthest draw-off point in the circulating system. It is important to maintain temperatures at above this figure (Legionellae organisms will survive for only a short period of time above this temperature - approximately two minutes).

Periodic performance monitoring and a system of continuous monitoring and recording of water temperatures via a building management system (BEMS) or data logger is essential to ensure compliant system performance.

The outflow water temperature, under prolonged maximum continuous demand (at least 20 minutes) from calorifiers should not be less than 60°C.

While it is accepted that occasionally under peak instantaneous or prolonged demand the water outflow temperature will fall, it is not acceptable if this occurs frequently (more than twice in any 24 hour period) and/or for long periods (exceeding 20 minutes).

Under no circumstances should the domestic hot water flow temperature fall below 50°C.

It is recommended that disinfection by pasteurisation is undertaken if the water temperature of the calorifier falls below 45°C. A minimum domestic hot water circulation (return) temperature of 50°C shall be maintained during the hours of occupancy.

4.1.3 Cold Water System

All domestic cold water storage cisterns and tanks shall comply with the requirements of the Scottish Water Byelaws.

Duplicate tanks often create a risk of water becoming stagnant in one of them, leading to risk of Legionella, Pseudomonas Spp or similar contamination. Consideration should be given to taking one of the tanks out of service. See guidance in "Guidance for Alterations to Water Systems".

All cold water storage tanks are to be examined and the temperature tested on a regular summer / winter six monthly cycles and cleaned on an annual basis as required.

Temperatures in cold water storage tanks and the mains inlet to them should be checked during periods of high ambient temperatures (e.g. summer afternoons between June and August). Water temperatures should be less than 20°C.

At the same time, the furthest and nearest draw off points in the system should be checked to ensure that the water distribution temperatures are less than 20°C within 1 minute of running the water (at full flow). A similar temperature check regime should be undertaken during the winter months to identify the performance of cold water distribution systems and the impact of heat gain from heating systems.

4.1.4 Cold Water System Dump Valves

The cold water system installed in the Adult & Childrens Hospitals has a dump valve arrangement incorporated into the ground floor, 1st floor and 2nd floor layouts. The positions of the dump valves are shown on the Schneider BMS STRUXUREWARE system and connected via the KNX network.

Operating parameters for the dump valves are as follows:

Open at 23°C

Close at 20°C

4.1.5 End of Line Sensors (EOLs)

The hot and cold water system also incorporates End of Line (EOL) sensors which monitor the temperatures at specific sentinel points across all 11 floors of the Adult & Childrens installation. These can also be viewed via the Schneider BMS system.

4.1.6 Sampling

General microbiological and Legionella sampling in hot & cold water systems

Circumstances under which samples are taken:

- prior alterations to an existing water system;
- as part of commissioning process, prior to handover of a new building or introduction of a (altered, refurbished or new) water system into use;
- one week following handover of a new building or new water system;
- as part of the tank cleaning and disinfection process;
- as part of an assessment programme;
- in response to taste, odour or sustained discoloured water complaints.

When such samples are taken, a mains supply sample should be taken as a control to verify whether the supply could be the source of the identified problems. Scottish Water should also be contacted for distribution zone water quality data.

4.1.7 WS01 – Little Used Outlets

Control of Legionella in Water Systems, Intermittently used Water Outlets and Showers, Standard Operating Procedure WS01.

The Estates department is required to ensure that on a quarterly basis the list of ‘intermittent’ or ‘infrequently’ used water outlets or showers is reviewed to ensure it is accurate and up to date. Records of these reviews will be held within the system logbooks held locally.

If after investigation the taps or appliances identified within the reviewed list are deemed not necessary wherever possible the supply should be cut and the appliance removed from the water system. Where this is not possible then pipe work shall be cut back as close to the main circulating line as practicable to ensure that any dead-leg formed is minimised.

Nursing and other staff must be made aware of the issues surrounding legionella contamination and the link to low and underused water outlets and their assistance in formally identifying these possible outlets are sought.

Upon acknowledgement from the clinical staff of any intermittent or infrequently used outlets, the records are held on the Estates shared drive under Water Quality / WS01.

Any request from clinical staff regarding the removal of any intermittent or infrequently used outlets is assessed and surveyed by the AP (Water). If deemed appropriate a job is raised on FM for the Plumbing Technicians to remove, this is documented in the WS01 Records file in the Water Quality file on the shared drive. Subsequent hot and cold water pipe drawings are updated by the CAD Technician CP (water) where and when appropriate.

FILLING IN LOG SHEETS

Good water hygiene depends on maintaining high standards of cleanliness and freshness, together with careful temperature control. This section contains details of checks and recording sheets (marked “Log Sheets”) to be filled in when checks and measurements are made to show that the necessary standards are being kept up. Alternatively, where an electronic PPM system is used, Procedure references should be entered.

Follow the instructions within the boxes and make entries as each task is completed. The tasks are all listed at the front of each section, weekly tasks at the front of the weekly section, monthly on the monthly and so on. The summary list of tasks in this section is to remind you of what is required.

The Task and Log Sheets can be copied as required, completed Log Sheets will be filed where indicated in Section 2. **FM First ticket number MUST be included in all logsheets.**

PLANNING

The tasks and forms are organised into weekly, monthly, quarterly and annual sections. Always aim to carry out tasks early in the period when they are due to leave an opportunity to do them later if an emergency delays your plans.

ASK

If you have difficulties with the forms or do not understand the tasks, ask your Supervisor or line manager for clarification or guidance.

CHECKING

Incomplete or incorrect records are unacceptable in that they are misleading and do not do justice to the effort put in to achieve standards. Each log sheet includes a space for comment and tells you to check that all the boxes are complete: do make use of the comment space and double check the form, otherwise the record will have gaps and whoever is responsible for auditing will concentrate on what is missing and may not give you credit for the work that has been done.

LOG INSPECTION

Anyone inspecting this log (either as part of the Management Control System or not) is invited to make an entry in the inspection of Log Book record in front of Section One.

SURVEY

For survey purposes all surveys will be carried out starting left to right, where 2 off access doors are available the left access shall be taken first. Surveys shall be undertaken from top to bottom.

EQUIPMENT FITTINGS AND MATERIALS

Prior to carrying out alterations/ additions to distribution systems, the Water Fittings and Materials Directory published by the Water Regulations Advisory Scheme, should be consulted. This directory lists all materials and fittings approved for use to satisfy the requirements of current Water Byelaws.

Details of all new materials and fittings used in installations should be noted and recorded on the specific work document or project file for future reference.

SYSTEM ADDITIONS AND ALTERATIONS

Any additions, modifications or improvements to the water distribution system are to be noted and recorded and system record's amended to reflect such changes.

HYGIENE PRACTICES

Care should be taken to ensure high levels of personal hygiene, clean hands, clean clothing and PPE or gloves is maintained at all times when working on wholesome water operations. Tools, equipment, instrumentation and material's shall be free from contamination and appropriately disinfected before use.

Items such as pumps and hoses used in contact with water used for domestic purposes must be stored separately, clearly identified (ie colour coded or labelled) and **MUST NOT BE USED FOR ANY OTHER PURPOSE.**

Refer to Section 2.2 for location of maintenance records for the above.

4.2 Maintenance Procedures Summary

This section contains information in relation to the operational and maintenance checks managed by QEUH NHS Staff and appointed contractors to minimise the risk of exposure to *Legionella* and other waterborne micro-organisms within the domestic water systems, and to improve water quality. Procedures are as per the recommendations and exemplar models given in SHTM 04-01 Part G.

Procedure Reference	Operation(s)	Record Form Ref	Frequency
P1C1	BMS Temperature Monitoring	(021)	Daily
P1CC1A	Manual Temperature Monitoring	(005a)	Daily
	Filtration Plant Checks	(028c)	Twice Daily

4.3 Daily Maintenance Tasks

Reference	Operation
4.31	BMS Temperature Monitoring
4.32	Manual Temperature Monitoring
4.33	Filtration Plant Checks

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.31 – BMS TEMPERATURE MONITORING**DAILY**

FM First Template No 826

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 26 para 3.11**RECORD FORM - (021)****PROCEDURE REF - P1C1****SCHEDULE REF – BMS 01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **DAILY** as a minimum:**Description of Works**

- Refer to the BMS Temperature Monitoring Schedule BMS 01.
- Log onto both STRUXUREWARE BMS and DISTECH BMS front ends and check all temperatures from listed locations.
- Complete Schedule BMS 01 to confirm all temperatures have been checked.
- Any temperatures found outside the defined parameters stated on the BMS Temperature Monitoring Schedule should be investigated and resolved immediately. Details must be entered on Record Form (021) and escalated to the Water Systems AP.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Schedule BMS 01 and Record Form (021) if required, ensuring that you date, sign it and enter FM First ticket number.
3. Return forms to the Water Systems AP.

NOTE: Both Struxureware and Distech BMS systems are capable of generating temperature trend logs. These logs will be checked on a regular basis by the Water Systems AP to confirm accuracy of information.

4.32 – MANUAL TEMPERATURE MONITORING**DAILY**

FM First Template No 830

IN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 26 para 3.15**RECORD FORM – (005a) (021a)****PROCEDURE REF - P1CC1A****SCHEDULE REF – MTM 01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **DAILY** as a minimum:**Description of Works**

- Refer to the Manual Temperature Monitoring Schedule MTM 01.
- MANUALLY visit each location and obtain and record temperatures from all plant as listed on Schedule MTM 01.
- Any temperatures found outside the defined parameters stated on the MTM 01 Temperature Monitoring Schedule should be investigated and resolved immediately. Details must be entered on Record Form (021a) and escalated to the Water Systems AP.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (005a) and (021a) if required, ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.33 – FILTRATION PLANT CHECKS**TWICE DAILY**

FM First Template No 836

IN ACCORDANCE WITH BOARD POLICY

RECORD FORM – (028c)**PROCEDURE REF – N/A****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **TWICE DAILY** as a minimum AM and PM:**Description of Works**

- Refer to the Filtration Plant Daily Checks Log sheet (028c).
- Complete all listed checks and ensure plant is running if selected as DUTY, or available to run if selected as STAND-BY.
- Details must be entered on Record Form (028c) and any issues escalated to the Water Systems AP immediately.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (028c) if required, ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.4 Weekly Maintenance Checks

Reference	Operation
4.41	Flushing of Rarely Used Water Outlets (Twice Weekly)
4.42	Flushing of Deadlegs & Drain Cocks (Twice Weekly)
4.43	Rotation of Water Services Duty/Stand-By Pumps
4.44	Operation and Checks to Emergency Deluge Shower/Eye Wash (Twice Weekly)

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.41 – FLUSHING OF INTERMITTENTLY USED WATER OUTLETS

FM First Template No 824

TWICE WEEKLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 101 para 6.36**RECORD FORM - (026a)****PROCEDURE REF - WS01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **TWICE WEEKLY** as a minimum:**Description of Works**

- Refer to the locations listed on Record Form (026a).
- Estates to arrange for the Schedule to be updated to record on a regular basis.
- Flush water from ALL outlets identified on Record Form (026a) at a minimum frequency of Twice Weekly for a minimum period of 3 minutes per tap outlet taking care not to cause splashing or exposure to water aerosols / droplets.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Form (026a) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

NOTES:

In circumstances where there has been a lapse in the flushing regime, the stagnant and potentially contaminated water from within the shower or tap and associated dead leg should be purged to drain without discharge of aerosols before the appliance is used.

NHSGG&C consider the cleaning of wash hand basins, toilets and showers etc by Domestic Services staff to fulfil the criteria of having been used /flushed

As part of the ward/departments standard cleaning schedule Domestic Services staff will clean all wash hand basins, showers, baths, WC's and bidets. For the purposes of Legionella and Pseudomonas control the Board deems this to be considered adequate to fulfil guidance on the use of water outlets.

4.42 – FLUSHING OF DEADLEGS & DRAIN COCKS

FM First Template No 827

TWICE WEEKLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 101 para 6.36**RECORD FORM - (026b)****PROCEDURE REF – WS01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **TWICE WEEKLY** as a minimum:**Description of Works**

- Refer to the locations listed on Record Form (026b).
- Estates to arrange for the Schedule to be updated to record on a regular basis.
- Flush water from ALL outlets identified on Record Form (026b) on a Weekly basis for a minimum period of 3 minutes per tap outlet taking care not to cause splashing or exposure to water aerosols / droplets. Drain Cocks to be purged to ensure the removal of any built up residue in the line.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Form (026b) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.43 – ROTATION OF WATER SERVICES DUTY/STAND-BY PUMPS

FM First Template No 820

WEEKLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 27 para. 3.24**RECORD FORM - (028a)****PROCEDURE REF - P1C3****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **WEEKLY**:**Description of Works**

- Inspect and confirm operation of all listed duty/stand-by pumps by interrogating the programmer to check hours run for each pump motor.
- Check pump rig and associated valves for correct operation, signs of damage, leakage or corrosion.
- Record all details on Record Form (028a)

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Form (028a) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.44 – OPERATION AND CHECKS TO EMERGENCY DELUGE SHOWERS/EYE WASH

FM First Template No 825

TWICE WEEKLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 57**RECORD FORM - (026c)****PRECEDURE REF – WS01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4**RISK CONTROL NOTICE - RCN 11/04**The following actions must be undertaken **TWICE WEEKLY**:**Description of Works**

- Refer to the locations listed on Record Form (026c).
- Operate shower for a minimum period of 3 minutes taking care not to cause splashing or exposure to water aerosols / droplets. Measure and record temperatures until discharge water drops to the same temperature as the incoming mains water.

NOTE: For thermostatic showers and taps, the outlet should be flushed on the full cold setting for 2 minutes, then again on the full hot setting for a further 2 minutes, using override setting where available. Cold water should be less than 20°C, Hot water should be between 55°C and 60°C, and Mixed water in the range 41-43°C.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Form (026c) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.5 Monthly Maintenance Checks

Reference	Operation
4.51	Sentinel Outlet Temperature Recording
4.52	DWS Calorifier – Temperature Checks & Blowdown

NOTE:

Completed Log Sheet to be submitted to Site Estates Manager / Authorised Person (Water) for authorisation and copies filed as indicated in Section 2.20.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.51 – SENTINEL OUTLET TEMPERATURE RECORDING

FM First Template No 828

MONTHLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 28 para 3.27**RECORD FORM - (005c)****PROCEDURE REF - P1C4****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **MONTHLY**:**Description of Work**

- Check the temperatures at the sentinel taps as defined in the local plan of the system being checked. NOTE: Where the sentinel is a TMV or TMT the temperature readings should be taken from the pipework or directly from the hot and cold supply.
- Using a calibrated temperature probe, check the temperature of water from the cold water tap does not rise above 20°C after running the tap for 2 minutes.
- Using a calibrated temperature probe, check the temperature of water from the hot water tap does not drop below 50°C whilst running the tap for 1 minute.
- Record all temperatures on Record Form (005c).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Form **(005c)** ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.52 - DWS CALORIFIER – TEMPERATURE CHECKS & BLOWDOWN

FM First Template No 821

MONTHLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 28 para 3.30**RECORD FORM - (005)****PROCEDURE REF - P1C4****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **MONTHLY**:**Description of Work**

- MANUALLY CHECK and record the flow and return temperatures on the domestic hot water system as defined on Record Form (005), using the temperature gauges fitted or a suitable surface temperature probe.
- MANUALLY CHECK and record the calorifier storage temperature at top and bottom gauges if fitted.
- The flow temperature to be at least 60°C and the return temperature shall be no less than 50°C
- MANUALLY CHECK and record the cold water feed temperature using the temperature gauges fitted or a suitable surface temperature probe.
- Blowdown drain valves (if fitted) on all calorifiers and expansion vessels by opening the drain valve 3 times, each time for a 3 minute period. Where required, the hose from the drain valve connection should be discharged to the nearest drain/gulley. If there is no drain valve make note on Record Form 005.
- Check all local pipework to and from calorifier is in good order and all insulation is intact.
- Operate all isolation valves through their full range of motion.
- Check, confirm and record operation of de-stratification pump.
- Record all information on the Record Form (005).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.

2. Complete Record Form (005) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.6 Quarterly Maintenance Checks

Reference	Operation
4.61	Shower Head and Flexible Hoses Disinfection/Replacement
4.62	DHWS Calorifier and Expansion Vessel - Flush
4.63	HORNE Tap Flow Restrictor Exchange
4.64	Review of Rarely Used Water Outlets and Changes In-Use
4.65	TMV/TMT & Thermostatic Shower Disinfection and Function Test (HIGH RISK)

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.61 SHOWER HEAD AND HOSE REPLACEMENT

FM First Template No 869
Schedules: 1997 to 2724

QUARTERLY

IN ACCORDANCE WITH SHTM 04-01 Part G (*VI July 2015*) Page 32 para 3.51

RECORD FORM - (005b)

PROCEDURE REF - P1C12 CURRENTLY CONTRACTED TO DMA CANYON WATER

HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4

The following actions must be undertaken every **THREE MONTHS**:

NOTE: If PALL filter is fitted it must be left in place and recorded as such on Record Form (005b)

Description of Work

- Exchange shower head and hose assembly inc sealing washer with new disposable unit. Place old shower head and hose assembly into re-sealable plastic bag.
- Check that the new head and hose package is intact;
- Open replacement new shower head and hose assembly sealed packaging, remove and fit following the manufacturer's instructions;
- Run water and flush for 3 minutes in accordance with Legionella Risk Assessment in such a way as to avoid the creation of aerosols;
- Check final temperature for comfort and working order and return shower appliance to use.
- Return redundant sealed unit with shower head and hose assembly to collection point for recycling in accordance with Waste Procedures;
- Record all actions on Record Form (005b).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Form (005b) ensuring that you date, sign it and enter FM First ticket number.
3. Return form to the Water Systems AP.

NOTE: This procedure replaces the previous Clean & Disinfect method from 1st April 2019

4.62 - DWS CALORIFIER AND EXPANSION VESSEL - FLUSH

FM First Template No 821

QUARTERLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 29 para 3.34**RECORD FORM - (006) and (023)****PROCEDURE REF - P1C6****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken every **THREE MONTHS**:**Description of Work**

- Flush each Domestic Hot Water Calorifier and Buffer vessel through its drain valve by opening the drain valve 3 times, each time for a 3 minute period. Where required, the hose from the drain valve connection should be discharged to the nearest drain/gulley.
- Record all actions on the top section of Record Form (006).
- Where the domestic hot water system has a circulation pump(s) fitted to circulate the hot water from the top to the base of the calorifier or the storage/buffer vessel, and the history data shows no sludge deposits during flushing, then this procedure should be risk assessed to determine if the maintenance frequency can be changed. This assessment should be recorded on Record Form (023).

NOTE: this flushing process can shock the hot water system, so only carry it out when there is no hot water demand and the calorifier is valved off from the system.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (006) and/or (023) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.63 – HORNE TAP FLOW RESTRICTOR EXCHANGE

FM First Template No N/A

QUARTERLY

IN ACCORDANCE WITH IC GUIDANCE

RECORD FORM – (See DMA Records)**PROCEDURE REF – WQS 001****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken every **THREE MONTHS**:**Description of Work**

PPE:- Surgical gloves should be worn when carrying out this task. Cross contamination of the replacement flow restrictor should be considered and avoided at all times.

Restrictor should only be replaced at outlets without PALL filters. If PALL filter is fitted it should be left in place and noted on Record Form.

- Assemble all tools and materials required for a complete task.
- Check with ward staff to ensure access can be granted to each area without Infection Control restriction.
- Remove existing restrictor using the appropriate tool and dispose of the restrictor in general waste.
- Use disinfectant to sanitise tap outlet and tools used before re-fitting new restrictor.
- Change gloves to avoid cross contamination of new components and tools.
- Unpack new restrictor components and insert into tap as per the manufacturer's instructions.
- Test on completion and fill out log sheet to record all relevant information.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Form (DMA WATER) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.64 - REVIEW OF INTERMITTENTLY USED WATER OUTLETS/CHANGE IN-USE

IN ACCORDANCE WITH BOARD POLICY

QUARTERLY**RECORD FORM – (001) (026)****PROCEDURE REF – WS01****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken every **THREE MONTHS**:**Description of Work**

- Liaise with Site Facilities Manager and Heads of Department to review existing accommodation occupancy and usage on a 3 monthly basis.
- Issue Quarterly circular email to all HoDs
- Identify any water services outlets that are not used OR changes to the occupancy.
- Schedule to be updated to record all areas which change in-use, become unoccupied or otherwise out of use.

CHECK

1. Record all details of any dept closures or little used outlets on Record Form (001) and add outlets to flushing register.
2. Ensure outlets are brought to the attention of the maintenance person carrying out the flushing activity and details added to Record Form (026)
3. All completed Record Forms to be stored in the building specific Log Book.

4.65 – TMV/TMT & THERMOSTATIC SHOWER DISINFECTION AND FUNCTION TEST (HIGH RISK)

QUARTERLY

FM First Template No

IN ACCORDANCE BOARD POLICY

RECORD FORM -**PROCEDURE REF -****HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4**The following actions must be undertaken every **THREE MONTHS**:**Description of Work**

- Examine all thermostatic taps for scale build-up or other deposits. De-scale any which are not clean.
- Check and remove any installed plastic flow straighteners from tap outlet
- Inspect and Clean and Disinfect filters / strainers by removing and immersing in a solution of 1000ppm free residual chlorine (50cc CLO2 in 5 litres of water) in water for 5 minutes.
- All HORNE Optitherm taps **MUST** have the flow straightener replaced during three monthly service tasks.
- Pasteurise outlets by over-riding thermostatic controls drawing water through each thermostatic tap until a temperature of 60°C is achieved. Run the tap at this temperature for five minutes. If this is not possible disassemble tap assembly and spray all accessible components with 'Shower Head plus' mixed to a 1:3 solution, (one part chemical, 3 parts water) or equal and approved and let stand for 5 minutes.
- Reassemble and verify fail safe operation by isolating hot and cold water supplies separately.
- Ensure thermostatic controls are re-adjusted to permit blending.
- Should controls not be able to be over-ridden, verify the temperatures at the inlet connections to the thermostatic valve utilising a contact type probe and electronic thermometer.
- Run and test tap and record hot and cold water inlet temperatures and mixed water outlet temperature.
- Log all actions.

4.7 Six Monthly Checks

Reference	Operation
4.71	TMV/TMT & Thermostatic Shower Disinfection and Function Test (Non-HIGH RISK)
4.72	CWST Inspection and Temperature Monitoring

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.71 – TMV/TMT & THERMOSTATIC SHOWER DISINFECTION AND FUNCTION TEST (NON HIGH RISK)

IN ACCORDANCE WITH BOARD POLICY

SIX MONTHLY**RECORD FORM -****PROCEDURE REF -****HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4**The following actions must be undertaken every **SIX MONTHS**:**Description of Work**

- Examine all thermostatic taps for scale build-up or other deposits. De-scale any which are not clean.
- Check and remove any installed plastic flow straighteners from tap outlet
- Inspect and Clean and Disinfect filters / strainers by removing and immersing in a solution of 1000ppm free residual chlorine (50cc CLO2 in 5 litres of water) in water for 5 minutes.
- All HORNE Optitherm taps MUST have the flow straightener replaced during three monthly service tasks.
- Pasteurise outlets by over-riding thermostatic controls drawing water through each thermostatic tap until a temperature of 60°C is achieved. Run the tap at this temperature for five minutes. If this is not possible disassemble tap assembly and spray all accessible components with 'Shower Head plus' mixed to a 1:3 solution, (one part chemical, 3 parts water) or equal and approved and let stand for 5 minutes.
- Reassemble and verify fail safe operation by isolating hot and cold water supplies separately.
- Ensure thermostatic controls are re-adjusted to permit blending.
- Should controls not be able to be over-ridden, verify the temperatures at the inlet connections to the thermostatic valve utilising a contact type probe and electronic thermometer.
- Run and test tap and record hot and cold water inlet temperatures and mixed water outlet temperature.
- Log all actions.

4.72 – CWST INSPECTION AND TEMPERATURE MONITORING:

FM First Template No 819

SIX MONTHLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 29 para 3.37**RECORD FORM – (003a) (003b)****PROCEDURE REF – P1C7****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4

The following actions must be undertaken every **SIX MONTHS** seasonally during Summer and Winter:

Description of Work

- Inspect the tank and associated pipework including insulation, valves etc for damage or corrosion and sediment.
- Operate all isolation valves through their full range of motion.
- Check the operation of the ball-valve by pressing down on it and lifting the float to confirm that water flows and stops.
- Inspect the tank overflows if visible. Confirm that there is no blockage or other foreign material and that the mesh screen is not damaged.
- Measure and record the temperature of the water in the tanks, by dipping the thermometer into the top as far from the ball-valve as possible.
- Check and record ambient outside air temp and tank room temp.
- Check the flow and record the temperature of water feeding the tanks. There should be a steady rapid flow when the ball float is down.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (003a) and (003b) ensuring that you date, sign them and enter FM First ticket number.
3. Return forms to the Water Systems AP.

4.8 Annual Maintenance Checks

Reference	Operation
4.81	DWS Calorifier / Expansion Vessel Inspection
4.82	Water Services Pipework and Distribution System Checks
4.83	Representative Tap Temperature Monitoring
4.84	Vibration coupling inspection
4.85	BMS Temperature Sensor Test and Calibration

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.81 - DWS CALORIFIER/EXPANSION VESSEL INSPECTION

FM First Template No 821

ANNUALLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 31 para 3.44**RECORD FORM - (006)****PROCEDURE REF - P1C9****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **ANNUALLY****Description of Work**

Follow the manufacturers' maintenance instructions from O&M manuals. Record all actions where applicable on Record Form (006) for each system.

- Isolate domestic hot water calorifier or hot, cold or chilled water storage/buffer vessel service valves;
- Heat any domestic hot water calorifier or hot water storage/buffer vessel up until the contents has reached 60°C and hold at this temperature for a period of at least 1 hour;
- Drain domestic hot water calorifier and expansion vessel and remove inspection hatch;
- Hose out the domestic hot water calorifier or hot and expansion vessel to remove any debris, scale or other deposit. Care should be taken to keep aerosols to a minimum;
- If the domestic hot water calorifier or expansion vessel does not have an inspection hatch, the pipework at the top of the vessel should be disconnected to allow the insertion of a water hose to allow debris to be washed down off internal surfaces;
- Examine the internal and external condition of the domestic hot water calorifier and expansion vessel and pipework, any defects should be reported in writing to the relevant Authorised Person (Water). The safety valve should be checked, overhauled and reset as necessary. The temperature and pressure gauges to be checked for operation.
- On completion of examination and any repairs, the domestic hot water calorifier and expansion vessel should be re-assembled and the following sequence must be undertaken:
 - Refill with cold water;
 - Drain the domestic hot water calorifier and expansion vessel;
 - Refill with cold water, leave cold feed valve open;
 - Run domestic hot water calorifier or hot water storage/buffer vessel at a temperature of 60°C for at least 1 hour. Test the operation of high limit cut-out system if fitted. Check the temperature of the calorifier/vessel top and bottom with a surface thermometer;

- Adjust any controls as necessary.
- Take bacteriological samples from the base of the calorifier and submit to GRI Water Lab for analysis. (THIS TASK TO BE CARRIED OUT BY DMA CANYON WATER)

NOTE: this flushing process can air lock the hot water system, so only carry it out when there is no hot water demand and the calorifier is valved off from the system.

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (006) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.82 - PIPEWORK AND DISTRIBUTION SYSTEM CHECKS

FM First Template No 829

ANNUALLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 31 para 3.**RECORD FORM - (0)****PROCEDURE REF -****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **ANNUALLY**:

Estates Manager or Water Systems AP will define areas to be checked in each building.

Description of Work

- Check all accessible pipework for damage, or corrosion.
- Check for missing or damaged pipework insulation

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (0) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.83 – REPRESENTATIVE TAP TEMPERATURE MONITORING

FM First Template No 917

ANNUALLYIN ACCORDANCE WITH SHTM 04-01 Part G (*V1 July 2015*) Page 32 para 3.39**RECORD FORM - (005d)****PROCEDURE REF – P1C10****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4

The following actions must be undertaken at regular intervals throughout the year to ensure 20% of the requirement is completed **ANNUALLY**:

Description of Work

- **OBJECTIVE:** Carry out water temperature monitoring to ensure consistency and performance of the system as per design. 20% of all outlets to be assessed annually to ensure entire system is completed within a 5 year period (*ref: SCART2 Question 54*)
- Check the temperatures at a representative number of hot and cold outlets on a rotational basis as defined in the local plan of the system being checked. Lead AP (Water) to define areas to be checked each month.
- Using a temperature probe check the temperature of the cold water tap does not go above 20°C after running the tap for 2 minutes;
- Using a temperature probe check the temperature of the hot water tap does not go below 50°C within running the tap for 1 minute;
- If the outlet being tested is protected by a TMV/TMT then temperatures should be taken directly from the supply pipework or by bypassing the thermostatic device by use of an appropriate purging kit.
- Record all temperatures and locations tested on the Record Form (005d).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (005d) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.84 - VIBRATION COUPLING INSPECTION

FM First Template No 831

ANNUALLY

IN ACCORDANCE WITH HSG 274 Part 2 (2014) Page 19 para 2.35

RECORD FORM - (008)**PROCEDURE REF – WQMS 001****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **ANNUALLY**:**Description of Work**

- Refer to list of vibration coupling locations to be assessed.
- Visually check the condition of the coupling for any signs of leakage, deterioration or corrosion.
- Ensure flexible portion of coupling is intact and free from damage or deterioration.
- Record all inspection details on the Record Form (008).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (008) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.85 – BMS TEMPERATURE SENSOR CALIBRATION

FM First Template No

ANNUALLY

IN ACCORDANCE WITH

RECORD FORM -**PROCEDURE REF –****HAISCRIBE/Risk Assessment Ref – N/A See Appendix 4**The following actions must be undertaken **ANNUALLY**:**Description of Work**

- This task should be included in the BMS Service Contract Specification.
- All temperature sensors related to domestic hot and cold water services to be checked and calibrated annually.
- All calorifiers, storage tanks, flow and return monitoring devices.
- Include all End of Line (EOL) sensors and cold water flushing devices.
- Records should be kept and made available to the estates dept on request.

4.9 Bi-Annual Maintenance Checks

Reference	Operation
4.91	Flexible Hose/Connection Inspection and Exchange
4.92	CWST Drop Test

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific 'Log Book' for the location being maintained.

4.91 – FLEXIBLE HOSE/CONNECTION INSPECTION AND EXCHANGE

FM First Template No

BI-ANNUALLY

IN ACCORDANCE WITH QEUH RISK ASSESSMENT RECOMMENDATIONS 2017

RECORD FORM - (009)**PROCEDURE REF – WQMS 002****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **ANNUALLY**:**Description of Work**

- Refer to list of flexible connection locations to be assessed as per WQMS 002.
- Visually check the condition of the coupling for any signs of leakage, deterioration or corrosion.
- Safely isolate the water services and exchange the flexible connection with a BRAND NEW UNUSED replacement.
- Apply tag/label to indicate the intended date of future replacement (todays date + 24 months)
- Record all details on the Record Form (009).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (009) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

4.92 – CWST DROP TESTS

FM First Template No 819

BI-ANNUALLY

IN ACCORDANCE WITH

RECORD FORM -**PROCEDURE REF -****HAISCRIBE/Risk Assessment Ref – N/A** See Appendix 4The following actions must be undertaken **ANNUALLY**:**Description of Work**

- Shut off mains cold water supply to tank.
- Record the start time and allow tank to drain naturally through usage. DO NOT OPEN THE DRAIN.
- Periodically monitor the tank until usage has reduced tank to exactly half of its starting capacity.
- Record the stop time and estimate the number of hours of storage of water in the tank.
- Record all inspection details on the Record Form (010).

CHECK

1. Record all details of any fault or discrepancy on the FAULT LOG and report to Manager.
2. Complete Record Forms (010) ensuring that you date, sign them and enter FM First ticket number.
3. Return form to the Water Systems AP.

5.0 INCIDENT AND EMERGENCY PROCEDURES

Procedure Reference	Operation
5.10	FAILURE OF CONTROL MEASURES
5.20	HIGH COLD WATER SUPPLY TEMPERATURE TO OUTLET
5.30	LOW HOT WATER SUPPLY TEMPERATURE TO OUTLET
5.40	CALORIFIER OR HEAT EXCHANGER TEMPERATURE FAULT
5.50	POSITIVE LEGIONELLA TEST RESULT
5.60	IDENTIFICATION OF LITTLE USED WATER OUTLET
5.70	EMERGENCY REPAIRS
5.80	DISINFECTION OF WATER SYSTEM
5.90	PSEUDOMONAS

NOTE:

Completed Log Sheet to be submitted to either the Authorised Person (Water Systems) or Site Manager Operational Estates for authorisation and copies filed as indicated in Section 2.2.

Due to the volume of information required for the recording of test results for each of the assets being maintained, the Log Sheets provided within this document are for indicative purposes only.

Detailed information on the assets and test records for same will be retained within the specific ‘Log Book’ for the location being maintained.

THE FOLLOWING PAGES DESCRIBE REMEDIAL ACTIONS TO BE TAKEN IN THE EVENT OF AN INCIDENT, EMERGENCY, OUT-OF-SPECIFICATION TEST RESULT AND / OR WHERE *LEGIONELLA* HAS BEEN IDENTIFIED AND/OR BACTERIA COUNTS BEING IN EXCESS OF THE RECOMMENDED LIMITS IN THE WATER SYSTEM ARE IDENTIFIED.

The Health and Safety at Work Act places a duty on employers to ensure, so far as is reasonably practicable, the maintenance of safe working conditions without risks to health, not only to employees, but also to the general public.

The risk to personnel associated with the presence of *Legionella* depends on a number of variables and may be quite low. However, since the actions to eradicate it are straightforward and reasonably practicable, it would be wise to put them in hand without delay if *Legionella* has been identified.

When analysis confirms that the levels of bacteriological contamination are in excess of acceptable limits, and/or the presence of Coliforms or *E.coli* is identified, the procedures recommended in this section should be applied.

5.1 Failure of Control Measures:

Where any reported test result, non-compliance issue or defect is made known which affects the integrity of the water system and indicates the failure of Control Measures and / or increased risk of Legionella the following procedures shall be followed and duly recorded within Section 2.3 of this document and brought to the attention of the relevant Infection Control Team and Water Management Group.

IN ALL CASES THE INCIDENT RECORD FORM (004) SHOULD BE COMPLETED AND INSERTED IN THE BUILDING SPECIFIC WATER SAFETY LOG BOOK.

5.2 High Cold Water Supply Temperature

Incident Plan

In the event of plant failure suppliers and installers guidance should be consulted. The location of all relevant literature should be recorded in the site logbook (e.g. Mercury fault finding guidance).

Mains and Stored Water

Currently there is no legal maximum water supply temperature from the Licensed Provider. In practice the water supply temperature to boundary point will be subject to seasonal variation. In winter this would normally be expected to be in the 5°C – 10°C range and in summer up to 20°C.

The following staged risk assessment escalation procedure should be employed where the water temperature in Cold Water Storage Tanks is 20°C or higher.

Stage 1 - Verification

- Where tepid cold water occurrence (i.e. $\geq 20^{\circ}\text{C}$) is reported from any numbers of cold water outlets, from maintenance/ppm, flushing procedures, from BEMS monitoring, or from the manual monitoring of storage tanks, the person identifying, or making a report must notify the relevant Authorised Person (Water) as soon as the problem is identified and confirm this in writing within 24 hours;
- The Authorised Person (Water) should liaise with the person identifying the problem and verify the problem by independently re-checking by means of taking the water temperature of the appropriate cold water storage tank, the temperature of each incoming mains supplies at the site boundary point (and building entry points of other buildings within the QEUH campus served by the same mains lines) and the outflow distribution temperature;
- If the cold water storage temperature is confirmed as being 20°C or higher at any of the above noted points, then the Authorised Person (Water) should record this in writing as well as conducting continuous monitoring of the incoming cold water mains, the cold water storage and the outflow temperatures to establish the temperature profiles and in more detail over at least a one week period to determine the level of risk;
- If only one of the incoming mains lines is $\geq 20^{\circ}\text{C}$ the consideration should be given to switching to the other mains supply until such times as “out-of-specification” mains line has returned to compliant parameters. Ensure if either mains line is non-operational it is included in a daily flushing regime and treated as per escalation procedures to follow.
- The Authorised Person (Water) should also review the Water Safety Log Book and take into account the recent water system history specifically to include:
 - the primary water treatment levels (for mains cold water supplied with Chlorine or Chloramination treatment);
 - any water sampling results;
 - system monitoring data including temperature monitoring and water quality chlorine or chloramination checks;
 - recent maintenance history; recent alterations, changes or additions to the water system;
 - any other changes made by Duty Holders or users of the water system; On reviewing continuous monitoring temperature profiles action as Stage 2, 3 or 4 as appropriate of this escalation procedure should be undertaken. The Authorised Person (Water) will ensure that the Responsible Person (Water) is notified immediately in writing at each stage and also recorded in the Water Safety log book.

Stage 2 - Initial Action – High Incoming Mains Cold Water Temperature

- Where the incoming mains cold water is 18°C or higher for more than a 48 hour period the Responsible Person (Water) should contact Business Stream (the Licensed Provider) who will work with Scottish Water to establish the reasons and determine a resolution. Continuous monitoring should continue and recorded in the risk assessment

Stage 3 - Water temperatures fluctuating above and below 20°C (but not higher than 25°C)

- Where water temperatures are fluctuating above and below 20°C in a regular cyclical manner over 72 hour periods in response to regular user water demand (but not higher than 25°C) and are more than 2°C higher than the incoming cold water mains supply temperature at the building entry point, then continuous monitoring should be continued by the Authorised Person (Water). The reason(s) for failure(s) should be identified and rectified as soon as possible. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there may be increased risk and appropriate actions may be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained).
- considerations for failures include:
 - accuracy of temperature sensors (requiring recalibration);
 - temperature sensors being located in water (requiring reposition where tank storage levels been reduced and sensor no longer sensing stored water);
 - inappropriate standby tank configuration;
 - temperature sensor in standby system;
 - temperature sensor measuring stagnation (requires reposition);
 - inappropriate siting (not in a cool location);
 - heat gain to the tank and pipework (due to lack of appropriate insulation or located close to heat gain from other heat sources);
 - storage capacity not minimised to match daily use (12 hours storage is recommended);
 - ingress of hot water through cross connection or mixing valve failure (i.e. from DHW system or MTHW systems);

Stage 4 - water temperatures fluctuating above and below 25°C (and rarely below 20°C)

- In this situation continuous monitoring should be continued by the Authorised Person (Water), the reason(s) for failure(s) (as Stage 3) identified and rectified on an urgent basis. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there will be an increased risk and appropriate actions will be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained);
- In this situation a permanent solution, such as ventilation for the plant room, or changing the water storage arrangements, or forming a circulating distribution system (with or without chilling depending on the circumstances) would require to be implemented;
- The Authorised Person (Water) should, unless instructed in writing to the contrary by Responsible Person (Water) implement the following:
 - o arrange to drain the tank contents and clean if necessary (*and/or carry out local disinfections where appropriate*);
 - o inform the users of the failed system that they must not draw off any water from the affected system until further notice;
 - o suitable disinfection of the tank and/or distribution system shall be carried out.

Please Note: *Due to the system design and installation complete disinfection of all downservices fed from the Raw and Bulk water storage tanks may not be practical as “high risk” system such as renal dialysis is fed from these tanks. Alternative protocols/method statements for local disinfections should be prepared and maintained;*

- o thereafter the tank/local area being disinfected shall be brought back into service;
- o finally the users shall be informed that the system is back in operation.

The Authorised Person (Water) shall complete an Incident Report Record Form. An entry should also be made in the Water Safety Log Book and the Responsible Person (Water) should be notified in writing as soon as possible.

5.3 Low Hot Water Supply Temperature

Incident Plan

In the event of plant failure suppliers and installers guidance should be consulted. The location of all relevant literature should be recorded in the site logbook (e.g. Mercury fault finding guidance).

Mains and Stored Water

Currently there is no legal maximum water supply temperature from the Licensed Provider. In practice the water supply temperature to boundary point will be subject to seasonal variation. In winter this would normally be expected to be in the 5°C – 10°C range and in summer up to 20°C.

The following staged risk assessment escalation procedure should be employed where the water temperature in Cold Water Storage Tanks is 20°C or higher.

Stage 1 - Verification

- Where tepid cold water occurrence (i.e. $\geq 20^{\circ}\text{C}$) is reported from any numbers of cold water outlets, from maintenance/ppm, flushing procedures, from BEMS monitoring, or from the manual monitoring of storage tanks, the person identifying, or making a report must notify the relevant Authorised Person (Water) as soon as the problem is identified and confirm this in writing within 24 hours;
- The Authorised Person (Water) should liaise with the person identifying the problem and verify the problem by independently re-checking by means of taking the water temperature of the appropriate cold water storage tank, the temperature of each incoming mains supplies at the site boundary point (and building entry points of other buildings within the Southern General Hospital served by the same mains lines⁸) and the outflow distribution temperature;
- If the cold water storage temperature is confirmed as being 20°C or higher at any of the above noted points, then the Authorised Person (Water) should record this in writing as well as conducting continuous monitoring of the incoming cold water mains, the cold water storage and the outflow temperatures to establish the temperature profiles and in more detail over at least a one week period to determine the level of risk;
- If only one of the incoming mains lines is $\geq 20^{\circ}\text{C}$ the consideration should be given to switching to the other mains supply until such times as “out-of-specification” mains line has returned to compliant parameters. Ensure if either mains line is non-operational it is included in a daily flushing regime and treated as per escalation procedures to follow.
- The Authorised Person (Water) should also review the Water Safety Log Book and take into account the recent water system history specifically to include:
 - the primary water treatment levels (for mains cold water supplied with Chlorine or Chloramination treatment);
 - any water sampling results;
 - system monitoring data including temperature monitoring and water quality chlorine or chloramination checks;
 - recent maintenance history; recent alterations, changes or additions to the water system;
 - any other changes made by Duty Holders or users of the water system;
 - On reviewing continuous monitoring temperature profiles action as Stage 2, 3 or 4 as appropriate of this escalation procedure should be undertaken. The Authorised Person (Water) will ensure that the Responsible Person (Water) is notified immediately in writing at each stage and also recorded in the Water Safety Logbook.

Stage 2 - Initial Action – High Incoming Mains Cold Water Temperature

- Where the incoming mains cold water is 18°C or higher for more than a 48 hour period the Responsible Person (Water) should contact Business Stream (the Licensed Provider) who will work with Scottish Water to establish the reasons and determine a resolution. Continuous monitoring should continue and recorded in the risk assessment.

Stage 3 - water temperatures fluctuating above and below 20°C (but not higher than 25°C)

- Where water temperatures are fluctuating above and below 20°C in a regular cyclical manner over 72 hour periods in response to regular user water demand (but not higher than 25°C) and are more than 2°C higher than the incoming cold water mains supply temperature at the building entry point, then continuous monitoring should be continued by the Authorised Person (Water). The reason(s) for failure(s) should be identified and rectified as soon as possible. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there may be increased risk and appropriate actions may be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained).
- considerations for failures include:
 - accuracy of temperature sensors (requiring recalibration);
 - temperature sensors being located in water (requiring reposition where tank storage levels been reduced and sensor no longer sensing stored water);
 - inappropriate standby tank configuration;
 - temperature sensor in standby system;
 - temperature sensor measuring stagnation (requires reposition);
 - inappropriate siting (not in a cool location);
 - heat gain to the tank and pipework (due to lack of appropriate insulation or located close to heat gain from other heat sources);
 - storage capacity not minimised to match daily use (12 hours storage is recommended);
 - ingress of hot water through cross connection or mixing valve failure (i.e. from DHW system or MTHW systems);

Stage 4 - water temperatures fluctuating above and below 25°C (and rarely below 20°C)

- In this situation continuous monitoring should be continued by the Authorised Person (Water), the reason(s) for failure(s) (as Stage 3) identified and rectified on an urgent basis. This should be recorded by updated risk assessment (specifically in relation to the patient risk rating – where there will be an increased risk and appropriate actions will be required to mitigate exposure. An up to date register of all areas and their subsequent patient risk ratings should be maintained);
- In this situation a permanent solution, such as ventilation for the plant room, or changing the water storage arrangements, or forming a circulating distribution system (with or without chilling depending on the circumstances) would require to be implemented;
- The Authorised Person (Water) should, unless instructed in writing to the contrary by Responsible Person (Water) implement the following:
 - o arrange to drain the tank contents and clean if necessary (*and/or carry out local disinfections where appropriate*);
 - o inform the users of the failed system that they must not draw off any water from the affected system until further notice;
 - o suitable disinfection of the tank and/or distribution system shall be carried out.

Please Note: *Due to the system design and installation complete disinfection of all downservices fed from the Raw and Bulk water storage tanks may not be practical as “high risk” system such as renal dialysis is fed from these tanks. Alternative protocols/method statements for local disinfections should be prepared and maintained;*

- thereafter the tank/local area being disinfected shall be brought back into service;
- finally the users shall be informed that the system is back in operation.

The Authorised Person (Water) shall complete an Incident Report Record Form. An entry should also be made in the Water Safety Log Book and the Responsible Person (Water) should be notified in writing as soon as possible.

Hot Water Services

When hot water storage or distribution temperatures fall below those required (60°C storage, 55°C at outlets and returning to calorifier) these will almost inevitably be caused a mechanical fault. Appropriate maintenance procedures, including the Mercury Fault Finding guidance documents, should be created and referenced to assist in timely rectification.

This escalation procedure (taken from SHTM 04-01 Part G (Draft)) should be employed if the Calorifier/Plate Heat Exchangers outflow temperature falls below 45°C.

The table below should be used to decide on the actions necessary in the event of a plant breakdown such as power failure or gas supply failure.

Breakdown leading to temperature <45°C, lasting for:	Risk Category	Action
<12 hrs	High	Verify
	Significant	Verify
	Moderate	Verify
>12 hrs	High	Thermally pasteurise
	Significant	Verify
	Moderate	Verify
>24 hrs	High	Thermally pasteurise
	Significant	Thermally pasteurise
	Moderate	Verify
>72 hrs	High	Thermally pasteurise
	Significant	Thermally pasteurise
	Moderate	Thermally pasteurise

In the event of a reduction in domestic hot water temperature the **Authorised Person (Water)** should be notified in writing as soon as possible. The reason for failure must be identified and rectified as soon as possible.

The **Authorised Person (Water)** shall notify the **Duty Holder** and users on the failed system that they must not draw off any hot water from the affected services until further notice.

The relevant **Duty Holder** shall ensure that their staff are aware of the situation, and that they in turn shall prevent patients from using affected services.

Where thermal pasteurisation is to be carried out, the temperature of the calorifier or plate heat exchanger shall be raised to 70°C, and the water shall be circulated throughout the affected distribution system for at least one 1 hour. Each tap or appliance should be run in sequence until full temperature is achieved (this should be measured). To be effective the temperature in the calorifier or plate heat exchanger should be high enough to ensure that all distribution outlets receive water at a temperature of greater than 60°C. Ensure the return flow to the calorifier or plate heat exchanger is no less than 55°C.

The **Authorised Person (Water)** shall inform users that the system is back in operation.

Bacteriological samples should be taken in consultation with the Infection Prevention and Control team.

The **Authorised Person (Water)** shall complete an Incident Report Record and ensure the **Responsible Person (Water)** is notified in writing as soon as possible. Maintain hard copy records in the Water Safety Log

5.4 Positive Legionella Test Result

Microbiological Sampling (Legionella)

Sampling requirements and frequency are to be formulated by NHS GG&C and written scheme should be updated as appropriate.

Legionella testing may be required:

- In systems where the temperature control regimes are not consistently achieved, frequent testing e.g. weekly should be carried out to provide early warning of loss of control. Once the system is brought back under control as demonstrated by monitoring, the frequency of testing should be reviewed
- Weekly checks are recommended until the system is brought under control;
- When an outbreak is suspected or has been identified;
- In wards with at-risk patients – for example those who are immuno-compromised (“high risk patient” areas still to be confirmed to DMA).

As a minimum, samples should be taken as follows:

- From the cold water storage and the furthestmost outlet from the tank, on every loop;
- From the calorifier flow, or the closest tap to the calorifier, and the furthestmost tap on the hot water service circulating system (these should be identified on sentinel outlet register);
- Additional samples should be taken from the base of the calorifier via drain valves;
- From areas where the target control parameters are not met (i.e. where temperatures are below 55°C for hot water systems or $\geq 20^{\circ}\text{C}$ for cold water systems);
- From areas subject to low usage, stagnation, excess storage capacity, dead legs, excessive heat loss, crossflow from the water system or other anomaly.
- High Risk Patient Areas
- Additional random samples may also be considered appropriate where systems are known to be susceptible to colonisation.

The temperature control regime is the preferred strategy for reducing the risk from *Legionella* and other waterborne organisms in water systems. This will require monitoring on a regular basis. The recommended test frequencies for various outlets are set out in Table 2 in Section 7.

HSG 274 Part 2 Table 2.3 Actions to be taken following legionella sampling in hot and cold water systems in healthcare premises with susceptible patients

Legionella bacteria (cfu/Litre)	Action required
More than 100 but less than 1,000	Low risk area Estates action only If only one or two samples are positive, system should be re-sampled. If a similar count is found again, a review should be carried out to identify any remedial actions a) If the majority of samples are positive, the system may be colonised, albeit at low level, with Legionella. Disinfection of the system should be considered but an immediate review of control measures and risk assessment should be carried out to identify any other remedial actions required. If remedial action is ineffective further measures will be discussed and approved by the Board Water Safety Group
More than 100 but less than 1,000	High Risk areas Impact on patient care Discuss results with ICD and agree actions and any closure of area.
More than 1,000	Low Risk Estates action only The system should be re-sampled and an immediate review of the control measures and risk assessment carried out to identify any remedial actions, including possible disinfection of the system. If remedial action is ineffective further measures will be discussed and approved by the Board Water Safety Group
More than 1,000	High Risk areas Discuss results with ICD and agree actions and any closure of area.

Communication pathway for Legionella results from water samples:

Water samples are sent to; UKASS-accredited laboratories which provide this service for NHS and other organisations that manage buildings. Reports will come back initially to the estates department.

Negative water samples are recorded as part of the documentation of Legionella control. If they are related to investigation of an “incident” such as a clinical case or a previous positive sample then these results are communicated to those managing that incident.

The information on the report which needs to be communicated is:

- Date of sampling
- Location and type of water outlet
- Identification of the organism, (Legionella pneumophila with serogroup, or Legionella species other than L pneumophila.)
- Count of organisms per Litre.

Estates will

- Inspect the system and take further action in accordance with HSE guidance and locally agreed procedures
- Inform Charge Nurse and or Clinical Nurse Manager of the Clinical Area concerned if appropriate of any control measures being taken/required
- Inform GM for the Sector if appropriate.

The results of this initial risk assessment must be communicated to all those noted above and also to the Facilities General Manager for the site involved.

The Infection Control Manager for Infection Prevention and Control will inform NHS GG&C

If there is impact on patient care then an Incident Management Team (IMT) may be convened to assess the risk and further actions.

See table in Appendix 2

5.5 Intermittent or Infrequently Used Water Outlets

If after investigation the taps or appliances identified within the reviewed list, to be updated on a quarterly basis, is deemed not necessary wherever possible the supply pipe work shall be cut back as close to the main circulating line as practicable to ensure that any dead leg formed is minimised and the appliance is removed from the water system.

In circumstances where there has been a lapse in the flushing regime, the stagnant and potentially contaminated water from within the shower or tap and associated dead leg should be purged to drain without discharge of aerosols before the appliance is used.

Where a ward or department is closed or taken out-of-use for an extended period of time e.g.: pending refurbishment, change in-use or other reason, arrangements shall be put in place to ensure the regular flushing and recording of water outlets within such areas. If such closures are considered to be long term or permanent consideration should be given to the disconnection of all water services to the affected areas.

5.6 Emergency Repairs

Emergency repairs may be required at any time and should be undertaken by trained and competent personnel. Such repairs can vary from a simple repair to a section of pipework, replacement of a component or major burst or loss of service. In all such cases the integrity and safety of the water distribution system must be maintained at all times.

5.7 Disinfection of Water System and Components

There are a number of different chemical and thermal disinfection methods available ALL of which shall be undertaken by trained and competent personnel in strict accordance with all Statutory Requirements, Safety Precautions and Manufacturers Instructions.

Disinfection - is the process of destroying or inactivating Pathogenic organisms and is generally applied to the water supply.

Sterilisation – is the process of destroying or inactivating all Organic Life Forms and is generally applied to all systems of transmission and storage materials.

In ALL instances no matter what disinfection method is employed, due regard shall be taken of patient groups, specialist equipment and processes which may be sensitive to the disinfection process being used – eg Renal Dialysis patients **must not** be exposed to Silver Hydrogen Peroxide chemicals as such the RO Water Treatment Plant and Dialysis Machines must be disconnected from the water system until the disinfection process is completed.

Silver Hydrogen Peroxide should NOT be used for a period of 90 days or longer, as required by the Drinking Water Inspectorate.

The disinfection process may be required for the following situations:

REPAIRS -	Repair fittings and exposed pipe ends should be clean and disinfected before use. Such items should be sprayed with a suitable disinfection solution such as a Sodium Hypochlorite @ a strength of 1000 mg/l (1000ppm) with a minimum contact time of 5 minutes or equal and approved.
MINOR ALTERATIONS -	Pipework should be cleaned internally by spraying with a suitable disinfection solution such as a Sodium Hypochlorite @ a strength of 1000 mg/l (1000ppm) or where pipes are long and internal surfaces cannot be reached with sprays then a swab soaked in a solution of 50mg/l (50ppm) with a contact time of one hour or equal and approved.
NEW SUPPLY PIPEWORK -	Pipes are filled with a solution such as a Sodium Hypochlorite @ a strength of 20 mg/l (20ppm) with a contact time of 24 hours. Or Sodium Hypochlorite and water at a strength of 50mg/l (50ppm) for a contact period of one hour. Minimum free chlorine after one hour – 30mg/l (30ppm) or equal and approved
SYSTEM DISINFECTION -	This will include water storage tanks and possibly the water distribution system. The advice and use of Legionella Control Association (LCA) approved contractors will be used for this purpose

NOTE:

Appropriate Method Statements and Risk Assessments will be compiled and obtained prior to any disinfection process commencing. Water Disinfection Risk Based Assessment Form (024) should be completed prior to any disinfection process being carried out. (SHTM 04-01 Part G (V1 July 2015) Page 38 para 5.9)

An alternative to chemical disinfection is to pasteurise the system. This involves increasing the temperature to greater than 60°C by increasing the thermostat setting at the calorifier or boiler and recirculation as necessary to maintain this temperature throughout for at least one hour. This should effectively sterilise the calorifier, and kill any *Legionella* organisms present.

The water should be flushed through the system more than once. It is important that all taps are run for at least 5 minutes (preferably longer) at full temperature to ensure that the complete system is pasteurised and that the hot water has reached all parts of the system.

5.8 Pseudomonas SOP

Standard Operating Procedure for minimising the risk of Pseudomonas

This SOP provides direction and guidance for ward based staff to meet their responsibilities as stated in *HPS(2013) Guidance for neonatal units (NNUs) (levels 1,2&3), adult and paediatric intensive care units (ICUs) in Scotland to minimise the risk of Pseudomonas aeruginosa infection from water*. This document refers to critical control points 2 – 4 (inclusive) only. (Critical points 1, 5 and 6 are considered in the NHSGGC Water Safety Policy 2013.

*High Dependency Units (HDUs) which are adjoining/ integrated with an ICU should be included in this guidance.

Responsibilities:

Senior Charge Nurses (SCNs) must:

- Follow this SOP.
- Ensure that they are aware of access issues to wash hand basins. Where access is an issue they must arrange for flushing to occur and document this.
- Keep records of daily flushing for at least one month within the Facilities Folder.
- Inform a member of the local Estates Team if this SOP cannot be followed in relation to flushing water outlets.
- Inform a member of the local Estates Team of infrequently used outlets which could be removed.
- Allow members of the local Estates Team access to complete maintenance as appropriate.

Estates must:

- Undertake actions deemed the responsibility of the local Estates Department as per the Water Safety Policy.
- Keep a record of outlets reported that are deemed to be infrequently used and actions taken by them to remove this risk.
- Provide a report of maintenance actions and issues/ anomalies to the Sector Water Safety Group.
- Support staff locally to undertake their responsibilities in terms of reducing risk associated with pseudomonas.

Domestic Services must:

- Ensure that water outlets are flushed at full flow for 1 minute (not causing splashing) as part of the cleaning process
- Ensure this is the first task completed of the day
- Record this in the Domestic services Compliance Checklist “Water Outlets”
- Ensure the Checklist is retained within the facilities Folder at ward level for one month

Managers must:

- Make this SOP available to their staff.
- Support SCNs in following this SOP.

Water Systems Group must:

- Keep this SOP up-to-date.
- Audit compliance with this SOP.
- Provide guidance via the Water Systems Policy.

Flushing Water Outlets

Flushing of water outlets is necessary to control the build-up of biofilm in water systems to reduce the risk of transmission of pathogens via the environment and equipment to patients.

The Senior Charge Nurse (SCN) in each unit has responsibility (under current guidance) to ensure that the following recommendations are complied with in their area. The SCN should ensure that:

All water outlets are flushed in high-risk environments (adult, paediatric and Neonatal ICUs and associated HDU's), daily, first thing in am for 1 minute at full flow (but not so that splashing goes beyond the basin). This must be recorded. This will be completed as part of the Domestic Services local work schedule for the area. This must be reviewed on a daily basis by the SCN and appropriate action taken when this is identified as not having been completed

Any problems or concerns relating to the safety, maintenance, reduced usage, any changes in use and cleanliness of all water outlets are identified and reported to the ICT and the Estates Department as relevant.

For more information refer to NHS Greater Glasgow and Clyde
'Water Systems Safety Policy Written Scheme and Operational Procedures'

Risk Assessment Review Guidance

Summary of L8 Management Tasks Required for L8 and SHTM 04-01 Compliance

	Guidance Documents	Allocated to
Regular check to ensure that legislation and guidance has not changed	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of all policies relating to legionella control (e.g. Maintenance, Water Treatment, Water Management, Energy) to ensure still valid and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of L8 Management Structure to ensure up-to-date and accurate	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of communication lines to ensure still accurate and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of escalation & emergency procedures to ensure still valid and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of duties allocated to site staff and ensure accurate and recorded	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of duties of sub-contractors and ensure accurate and recorded and contractors are suitably qualified/competent for tasks assigned to them (e.g. Water Hygiene contractors should be LCA Approved, Plumbing contractors should be SNIPEF and Water Safe Registered)	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of staff training requirements and update training matrix	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of method statements and risk assessments to ensure still valid and correct	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of site documentation to ensure all records up to date and present	L8 HSG 274 Pt 2 SHTM 04-01	
Regular update of "Patient Risk Rating" register for all areas of hospital.	SHTM 04-01 Part B	
Regular review of sentinel outlet locations register.	SHTM 04-01 Part B	
Regular review of primary, sub-ordinate and tertiary hot flow and return loops to reflect any system alterations.	HSG 274 Pt 2	
Regular review of plant and equipment maintenance schedules.	Manufacturer's Instructions	
Regular review of BEMS temperature sensor locations to reflect any system alterations	HSG 274 Pt 2	
Regular review of schematic/as-fitted drawings to ensure up-to-date and accurate	L8 HSG 274 Pt 2 SHTM 04-01	
Regular review of L8 risk assessment with a maximum period of two years between updates. (e.g. if change of use or changes in legislation or any other factor which could affect validity of current assessment)	L8 SHTM 04-01	

Appendix 4

HAISCRIBE Risk Assessments

All relevant HAISCRIBE risk assessments produced and approved for Water Systems related tasks are stored on the QEUH Shared Drive within the folder path “Water Quality>HAISCRIBE

QEUH and RHC Hospitals					
NHS GGC Annual Water Systems AE Audit					
Site Address:					
Queen Elizabeth University Hospital and the Royal Hospital for Children Hospital, 1345 Govan Rd, Glasgow G51 4TF					
Building	QEUH and RHC Hospitals	Date	4 th and 5 th February 2021	Auditor	Dennis H. Kelly
Staff Interviewed	Mel MacMillan and Kerr Clarkson				

Description of Levels of Risk:	
Very High	Urgent Remedial Action – Lp growth and aerosol opportunity with susceptible people present on site
High	Remedial Action is needed but not immediately – Lp growth opportunity is present
Medium	Acceptable risk but some concerns– Lp likely to be controlled but improvements should be sought
Low	Risk controlled and acceptable

Levels of Risk found during the Audit:

The levels of risk detailed below reflect the highest level of risk identified during the audit in that particular category.

The audit process reviews the following five areas:

Audited Topic	Level of Risk
B1 Risk Assessment	
B2 Schematic Drawings	
B3 Written Scheme Monitoring and Records	
B4 On Going Water Treatment	
B5 Task Completion	

Comments

There is a high level of completion of the required tasks at both hospitals and a significant improvement on the performance of the management and control systems compared to the audit that was completed in February 2020. Additionally, the record systems were simple to access and provided evidence of task and remedial action completion. There is a close working relationship with the main water hygiene contractor and this provides benefits in terms of the quality and speed of the delivery of the required tasks.

The on-site involved Estates staff at the two hospitals have a high level of technical understanding and have delivered significant improvements in the water hygiene processes and procedures compared to the audit that was undertaken on site 12 months ago.

There are ten recommendations made in this section of the audit and fourteen recommendations made in part A of this audit report. The total of 24 recommendations compares favourably and is a significant improvement on the forty three recommendations that were made in the same audit that was completed in February 2020.

Summary of Actions				
Actions		Risk Level	Completed Date	Signature
1.	It is recommended that NHS GGC formalise their approach to when risk assessments should be completed and reviewed and that a date for a review or a repeat of the QEUH and RHC risk assessment is agreed.			
2.	It is recommended that the timing and delivery of the new risk assessment/risk assessment review is clarified, agreed and implemented and that a minimum two year risk assessment review period is utilised going forward.			
3.	It is recommended that the drawings of the chlorine dioxide installations are acquired and added to the records as soon as possible.			
4.	It is recommended that schematic drawings are reviewed at least annually and amended and updated to reflect any water system changes.			
5.	It is recommended that section 4.51 on page 51 of the written scheme documented is amended to include reference to 55°C being the target temperature for domestic hot water outlets and not 50°C.			
6.	It is recommended that Scotmas are contacted and reminded that there is a need to complete and record the levels of chlorite that are being found in the hospital water systems.			
7.	It is recommended that a weekly check is made on the stock levels of chlorine dioxide feedstock chemicals as recommended in the HSG 274 document in para 2.100.			

8.	It is recommended that non TMV'd hot and cold outlets are identified in areas requiring HAI Scribes for panel removal in order that a picture can be built up of the hot and cold water temperatures in that particular area. It is recommended that the calorifier (2 in total in the building) are inspected internally on an annual basis as recommended in the HSG 274 document and also in the SHTM 04-01 document.			
9.	It is recommended that a search is made to attempt to find the missing temperature records for March and October 2020, and if found, that these records are added to the logbook.			
10.	It is recommended that TMV servicing report sheets are dated in future and that any remedial actions are recorded in a remedial action section in the logbook.			

Section B1 Risk Assessment		Y/N U/K, N/A or Partial	Comments	Risk Level
B1.1	Is there a written risk assessment in place for the building water systems?	Y	The risk assessment was undertaken by DMA Canyon Ltd.	
B1.2	Was the risk assessment completed and delivered to site within the past two years?	N	Risk assessment was completed in January 2019 with the on-site work having been completed between October and December 2018. The risk assessment is therefore just outside the 2-year recommended review period detailed in the SHTM 04-01 guidance. It is recommended that NHS GGC formalise their approach to when risk assessments should be completed and reviewed and that a date for a review or a repeat of the QEUH and RHC risk assessment is agreed.	
B1.3	Does the site/organisation have plans with regard to reviewing or redoing the risk assessment?	N	The 2019 risk assessment recommends a two year review period. It was confirmed during this audit that discussions will shortly be taking place Given that the current risk assessment is just outside the two-year review period stated in the SHTM 04-01, it is recommended that the timing and delivery of the new risk assessment/risk assessment review is clarified, agreed and implemented and that a minimum two year risk assessment review period is utilised going forward.	
B1.4	Does the risk assessment address all the water systems in the building?	Partial	Section 8 of the current risk assessment details 15 other water systems in the two hospitals and includes a brief description of each system as well as an initial assessment of risk. It further advises that specialists in each field are consulted to confirm the	

			risk assessment detail is reflective of the function of each water system. The recommendation associated with this question is covered in Part A of this audit.	
B1.5	Are there any systems that are defined as being excluded from the assessment in the RA scope?	Partial	Although the Hydrotherapy pool was mentioned in the list of additional water systems, the risk assessment document did state that the pool was not assessed in the risk assessment process. However, it did state on page 4 of section 3 of the report that the hydrotherapy pool was "covered under a separate assessment".	
Actions on Risk Assessment				
1. It is recommended that NHS GGC formalise their approach to when risk assessments should be completed and reviewed and that a date for a review or a repeat of the QEUH and RHC risk assessment is agreed. 2. It is recommended that the timing and delivery of the new risk assessment/risk assessment review is clarified, agreed and implemented and that a minimum two year risk assessment review period is utilised going forward.				
Section B2 Schematic Drawings		Y/N U/K, N/A or Partial	Comments	Risk Level
B2.1	Are schematic drawings available in the written scheme, or in some other place in the property?	Y	There is a note in the Smart Sheet electronic data management system detailing the locations of the soft copies of the drawings as being available on ZUTEC (electronic data storage system).	
B2.2	Do the schematic drawings show all the components of the water systems?	Y	The drawings are as fitted and detail the entire system configuration including all component parts.	

B2.3	Are the water system return legs shown on the schematic drawings?	Y		
B2.4	Are secondary and tertiary loops shown on the schematic drawings?	Y		
B2.5	Have any amendments been made to the schematic drawings?	N	As an example, Scotmas, who provided the chlorine dioxide dosing systems, are also contracted to supply drawings of the tank room pipework which was altered to allow for the installation of the dosage equipment. It was stated at the time of the audit that these drawings had not yet been created and delivered. It is recommended that the drawings of the chlorine dioxide installations are acquired and added to the records as soon as possible.	
B2.6	If amendments have been made are they signed and dated?	N/A	See comment B2.4 above.	
B2.7	Is there any indication that drawings are regularly inspected and updated if required?	Partial	It was stated that drawings will be checked during the working year as and when required. There is no formal process in place. Drawings will be inspected when required to trace valves for pipework isolation for example. It is recommended that schematic drawings are reviewed at least annually and amended and updated to reflect any water system changes.	
Actions on Schematic Drawings				

3. It is recommended that the drawings of the chlorine dioxide installations are acquired and added to the records as soon as possible. 4. It is recommended that schematic drawings are reviewed at least annually and amended and updated to reflect any water system changes.				
Section B3 Written Scheme, Monitoring and Records		Y/N U/K, N/A or Partial	Comments	Risk Level
B3.1	Is there a written scheme in place?	Y	The written scheme is entitled 'QEUEH Campus Water Systems - Written Scheme – Controlling the risks to Legionella and other harmful bacteria in Water Systems – 2019 Rev B'.	
B3.2	Is a copy of the written scheme available on site and does this include this building?	Y		
B3.3	Is there a statement in the written scheme of the expected “correct and safe operation” processes detailing targets for temperatures and other control measures?	Partial	The statement of correct and safe operations for the water systems can be found in section 4.1 of the written scheme document. Section 4.51 on page 51 details the target temperature for a domestic hot water outlet as being 50°C and not 55°C. It is recommended that section 4.51 on page 51 of the written scheme documented is amended to include reference to 55°C being the target temperature for domestic hot water outlets and not 50°C.	
B3.4	Is there any seasonal difference in the use profile of the water systems within this building?	N		

B3.5	Are any pieces of duty standby equipment in this building that require to be switched on a weekly basis, and do the records show that they are being switched?	N	Pump sets automatically change the lead pump on a daily basis and there is a record of checks on the pump sets in the log book.	
Actions on Written Scheme Monitoring and Records				
5. It is recommended that section 4.51 on page 51 of the written scheme documented is amended to include reference to 55°C being the target temperature for domestic hot water outlets and not 50°C.				
Section B4 On Going Water Treatment		Y/N U/K or Partial	Comments	Risk Level
B4.1	Is there any form of water treatment in use in the building?	Y	Incoming mains water is treated via a membrane filtration system and is filtered down to 0.2 micron. The filtered mains water is secondary disinfected using chlorine dioxide.	
B4.2	Is there any form of secondary disinfection in place for this building?	Y	There are a number of chlorine dioxide units installed throughout the QEUH and the RHC. These chlorine dioxide units automatically dose ClO ₂ to the hot and cold water as required. Dosing control is maintained via ClO ₂ probes installed throughout the building water systems.	
B4.3	Are the required checks for secondary disinfection levels being completed and recorded?	Partial	Discussions were held with the contractor, DMA Canyon Ltd, who complete the analytical testing of the water systems for chlorine dioxide levels. Tests are completed on the hot and cold water systems at 78 locations throughout the hospital. This does not cover all of the sentinel points in the hospital water systems but was deemed by NHS GGC to be representative of the levels	

			of chlorine dioxide that would be found throughout the hospital water systems. Tests are completed on a weekly basis and a full set of records were available from DMA Canyon Ltd. Scotmas, the suppliers of the chlorine dioxide dosing equipment, complete a monthly service check on the chlorine dioxide systems. This check used to include a measure of the chlorite levels but it is apparent that this element of the checks has been missed for the past year although it was completed in February 2021. In the HSG 274 guidance in para 2.100, there is a requirement for a weekly check to be made on the operation of the chlorine dioxide generators and also to check and record the levels of feedstock chemicals at each generator. It is recommended that Scotmas are contacted and reminded that there is a need to complete and record the levels of chlorite that are being found in the hospital water systems.	
B4.4	Are the required levels of disinfection being achieved in the building water systems?	Y	Cold water chlorine dioxide residuals are generally within accepted limits. The hot water chlorine dioxide levels are reduced as would be expected in a hot water system.	
B4.5	Is there a record of biocide stock levels in the written scheme?	Partial	Biocide stock levels are checked as part of the Scotmas monthly contract. These checks should be made on a weekly basis. It is recommended that a weekly check is made on the stock levels of chlorine dioxide feedstock chemicals as recommended in the HSG 274 document in para 2.100.	
B4.6	Is any of the building water base exchange softened?	N/A		
B4.7	Are service records for the base exchange softeners	N/A		

	available in the written scheme?			
B4.8	Is filtration in use in any of the building water systems?	Y	Mains water is treated via a membrane filtration system. There are three membrane filtration sets in the hospital to allow for servicing of any unit if required.	
B4.9	Are service records for the filtration equipment available in the written scheme?	Y	Veolia, the equipment supplier, has a service contract for the filtration equipment. The Veolia service records are held online and can be accessed when required. The records were accessed and demonstrated to the auditor during this audit.	
Actions on Ongoing Water Treatment				
6. It is recommended that Scotmas are contacted and reminded that there is a need to complete and record the levels of chlorite that are being found in the hospital water systems. 7. It is recommended that a weekly check is made on the stock levels of chlorine dioxide feedstock chemicals as recommended in the HSG 274 document in para 2.100.				

Section B5 Task Completion		Expected Task Levels	Actual Records	Comments	Risk Level
B5.1	Tank Inspections	2 with temperature taken twice per year	2	Tank inspections are undertaken by DMA Canyon Ltd.	
B5.2	Hot Water Storage	4	12	Details are held on the monthly calorifier record sheets.	

	Vessel blowdowns				
B5.3	Hot Water Storage Vessel Internal Inspections	1	1	These checks were recently started in December 2020 and will be completed by end of February 2021.	
B5.4	Shower/Spray Heads	4	4	Showers are replaced on a quarterly basis. This task is completed by DMA Canyon Ltd. Records of shower replacements were available in the estates office. A random selection of areas was sampled including ARU 1, 2, 3, 4 and 5, ward 8A and ward 11A. A full set of shower replacement records was available for each.	
B5.5	Hot Water Storage Vessel F and R Temps	12	12	The calorifier flow and return temperatures generally appear to be acceptable.	
B5.6	PH Ex F and R Temps	12	N/A		
B5.7	Hot Sentinel Temps	12	10	The record for the temperatures at the hot outlets appears to be missing for the months of March and October 2020. A lot of the temperatures that are recorded in the records are from the TMV outlet as it is not allowed to remove IPS panels without a HAI Scribe. This does not tell us what is going on in the hot and cold water elements of the water systems. The BMS does however have end of line sensors on the Adults and Children hospitals. The BMS alarms if the temperatures are getting out of specification at these sensors. It is recommended that non TMV'd hot and cold outlets are identified in areas requiring HAI Scribes for panel removal in	

				order that a picture can be built up of the hot and cold water temperatures in that particular area. It is recommended that a search is made to attempt to find the missing temperature records for March and October 2020, and if found, that these records are added to the logbook.	
B5.8	Hot Sec Loop Temps	12	10	Incumbent water hygiene supplier DMA advised secondary loop temperatures are taken whenever possible as part of the routine temperature monitoring programme. This is confirmed by the records in the logbook.	
B5.9	Tertiary Loop Hot Temperatures	4	10	As for comment 5.8	
B5.10	Hot Rep Temps	1	1	Incumbent water hygiene supplier DMA advised that secondary loop temperatures are taken whenever possible as part of the routine temperature monitoring programme. This will include non-sentinel outlet, or representative, temperatures. This is confirmed by the records in the logbook.	
B5.11	Cold Sentinel Temps	12	10	The record for the temperatures at the outlets appears to be missing for the months of March and October. A lot of the temperatures that are recorded in the records are from the TMV outlet as it is not allowed to remove IPS panels without a HAI Scribe. This does not tell us what is going on in the hot and cold water elements of the water systems. The BMS does however have end of line sensors on the Adults and Children hospitals. The BMS alarms if the temperatures are getting out of specification at these sensors. The recommendation for this is covered in the recommendation for section B5.7	

B5.12	Cold Sub Loop Temps	12	N/A		
B5.13	Cold Rep Temps	1	10	Incumbent water hygiene supplier DMA advised that representative temperatures are taken whenever possible as part of the routine temperature monitoring programme. This is confirmed by the records in the logbook.	
B5.14	POU Heater Temps	12	N/A		
B5.15	Expansion Vessels	2 – 12 Monthly to six-monthly	12	This is covered in the monthly calorifier checks which can be found in the logbook. These tasks are completed by Estates staff through the FM 1 st system. The QEUH and RHC expansion vessels are flow through units. The water is however encouraged to move on a monthly basis by opening the drain point for the vessel.	
B5.16	TMV's/TMT's	1	U/K	The logbook has records showing that tests are being completed on the TMV's. However, the report sheets for the TMV servicing are not dated so it is not possible to say when the work was completed. Additionally, there are comments regarding water flowing from TMV's after the slam tests have been performed. There are statements such as "new cartridge required". There is no indication if any of these issues have been addressed. It is recommended that TMV servicing report sheets are dated in future and that any remedial actions are recorded in a remedial action section in the logbook.	
B5.17	Little used outlet flushing	Past three months	>24	Flushing appears to be happening on a daily basis. In the RHC and the QEUH, from the beginning of November 2020 until then end of January 2021 there were 52 flushing records – this is well in excess of the twice weekly flushing requirement.	

B5.18	CIO2 testing	52	52	It was noted that the chlorite tests have not been completed for the past year. A recommendation covering this issue can be found in section 4.3.	
B5.19	Check on the cold water distribution pipework thermal insulation	1	1	In the written scheme it is confirmed that this should be completed on an annual basis. This is addressed while completing other tasks such as the monthly plant room checks, checks of cold water storage tanks and checks on calorifiers and TMV's. The fact that the insulation has been checked can be found on the calorifier monthly check sheets.	
B5.20	Tank Clean and Disinfection	1	1	The records show that the cold water storage tanks were cleaned and disinfected on the 31 st January 2020.	
B5.21	Legionella sampling	4	4	A sampling schedule is in place which covers the entire QEUH campus. Samples are taken from QEUH and RHC designated points on a monthly basis. The samples are taken by DMA Canyon Ltd and are submitted to the GRI labs. The results are then sent to Estates and they are stored in Section 22 the Campus Scart folder. Any out of specification results are listed on a separate spreadsheet. This spreadsheet contains the remedial actions that were completed in response to the out of specification result and the outcome in terms of retesting. Once an issue has been remediated and cleared the details are recorded on a further spreadsheet and this records the three clear results. This system has been in place since 2018.	
Actions on Task Completion					

8. It is recommended that non TMV'd hot and cold outlets are identified in areas requiring HAI Scribes for panel removal in order that a picture can be built up of the hot and cold water temperatures in that particular area. It is recommended that the calorifier (2 in total in the building) are inspected internally on an annual basis as recommended in the HSG 274 document and also in the SHTM 04-01 document.
9. It is recommended that a search is made to attempt to find the missing temperature records for March and October 2020, and if found, that these records are added to the logbook.
10. It is recommended that TMV servicing report sheets are dated in future and that any remedial actions are recorded in a remedial action section in the logbook.

Thanks

Subject: CRAG

Dear colleagues,

Just to keep everyone updated, the CRAG has been repeated today as per last week's discussions, the result is positive in our QEUH lab, and a sample is on its way down to Bristol for testing too. The clinical team have been informed.

Best wishes,

Ash

Hi Liz

Thank you for your reply and discussion regarding the interpretation of the Cryptococcal Ag results. The patient will be monitored , followed up and treated as Christine has advised in her email.

Kind regards
 Kathleen

Dear Kathleen, Christine et al.

As regards clinical interpretation of any test we are not really in a position to do that without recourse to the full clinical details so as far as our reports are concerned we can only report what we find.

The fact that we reported these as lateral flow positive only and NEAT specimen suggests that it was negative by the latex agglutination test and therefore could not be titred using that kit. In this particular case it was a very weak positive line even with the neat serum whereas we normally see much stronger positives. In fact we have subsequently titred the serum samples from 26.06.20 and 27.06.20 in tandem using the lateral flow and there is a very, very faint line on the 1:2 dilution for both and possibly a shadow on the 1:4 when looked at with a magnifying glass. In the days when we only had latex agglutination testing both of these specimens would have been reported as negative. It is however as you say a more sensitive test than the latex agglutination so it is still possible that some weak positives could represent early disease. The attached paper raises concerns over such low titres with a 34% false positive rate overall, with all the false positives represented by titres $\leq$ 1:5. It would be of interest to test a later serum sample to see if there has been any change.

The CSF sample was lateral flow negative in this patient and the panfungal PCR on the blood samples from 26th and 27th June have also been negative, although this latter test lacks sensitivity for cryptococcosis. Although fluconazole treatment is certainly not unreasonable in this patient and he should be monitored for further signs and symptoms I do not think based on this evidence that a full scale look for environmental sources is warranted at this stage. I cannot be definitive that these represent false positives, although it is likely and they are less than proof of infection. If the patient does deteriorate and reveals further evidence of cryptococcosis then as you know the first-line treatment would be an initial course of amphotericin B plus flucytosine, followed by long-term fluconazole.

I am sorry for any confusion over this testing and the likely interpretation but in this case the results are not clear cut.

With best wishes,

Liz

Subject: RE: CRAG

Hi Liz

Re our telephone conversation and a further conversation with Christine on 29.06.20, we discussed the reporting of the results of 2 blood samples :

1. Blood [REDACTED] Lab no [REDACTED] sent for BDG - and tested as requested for Cryptococcal Ag - verbal report : faint line will report as positive.
2. Blood [REDACTED] lab no [REDACTED] - sent for confirmation of Cryptococcal Ag - verbal report : faint line will report as positive

Both samples were Latex Agglutination - negative and was informed that the Antigen test is more sensitive

Printed reports issued :

1. **Requesting laboratory number:** [REDACTED]

CRYPTOCOCCUS NEOFORMANS ANTIGEN TEST

Cryptococcus neoformans antigen test:	POSITIVE (NEAT specimen)
--	--------------------------

Results comment:

Positive by lateral flow device only.

2. [REDACTED]

CRYPTOCOCCUS NEOFORMANS ANTIGEN TEST

Cryptococcus neoformans antigen test:	POSITIVE (NEAT specimen)
--	--------------------------

Results comment:

Positive by lateral flow device

A further 2 blood samples taken on 27.06.20 were also sent for confirmation

3 .Blood [REDACTED] Lab no [REDACTED] - sent for BDG - and also tested as requested for Cryptococcal Ag

Requesting laboratory number: [REDACTED]

CRYPTOCOCCUS NEOFORMANS ANTIGEN TEST

Cryptococcus neoformans antigen test:	POSITIVE (NEAT specimen)
--	--------------------------

Results comment:

Positive by lateral flow device

4. Blood [REDACTED] lab no [REDACTED] sent for confirmation of Cryptococcal Ag **positive** result .

CRYPTOCOCCUS NEOFORMANS ANTIGEN TEST

Requesting laboratory number: [REDACTED]

Cryptococcus neoformans antigen test:	POSITIVE (NEAT specimen)
--	--------------------------

Results comment:

Insufficient sample remained to perform titration
Positive by lateral flow device only.

The CrAg LFA pack insert (IMMY) this was used to test the 2 blood samples in our laboratory

The presence of two lines (a control line and a line in the test zone) regardless **of the intensity of the test line, including faint lines, indicates a positive result.** The control line is a migration control and not intended as a specimen addition control.

As raised by Christine , if the interpretation of the results are now being considered as false positives on the 4 separate sample detailed above, are the reports to be amended and updated with interpretative comments to aid the Clinicians with the diagnosis and treatment of the patient ?

Kind regards
Kathleen

Subject: CRAG

Good Morning Liz,

Thanks for discussing the case of the [REDACTED] with positive CRAG testing on 3 serial samples, last week. As we discussed at the time with Kathleen, , the performance of the test is very good in determining early cryptococcal infection and we agreed that fluconazole would be worth starting pending the CSF samples to exclude meningitis. As far as I understood from our discussion the latex agglutination is less sensitive a test and the fact that 3 separate samples were positive by Crag indicated that a false positive was less likely.

I now understand that this interpretation has changed and that there is now a view that the results were false positives on 4 separate samples? I would be grateful to be included in discussion going forward as to whether a follow up sample becoming negative post treatment would be a helpful way to understand the pathophysiology of a potential early infection being detected.

Hi John,

We discussed the recent paediatric case of *Cryptococcus* infection at our complex case meeting.

Interestingly as part of the discussion we identified the unique epidemiology in Glasgow since 2019 where 2 paediatric haem onc patients who had inpatient stays in QEUEH building, and 3 adult cases since 2018 had at least a few nights inpatient stays also developed cryptococcosis. In the same time period there is a one case that I have not been able to identify if they had any inpatient stays. So in 5/6 confirmed cases in Glasgow there is an epi link to QEUEH site. This was noted by a relative of one of the cases that were identified at another hospital previously apparently.

This is really very striking given that between us all at the meeting, spanning over 20 years practice in GGC we can recall only 1 or two non HIV cases (one Hep B case I was involved in).

Just wanted to make sure that you were in the loop re the other 2 cases also having had inpatient stays at QEUEH. I copy in Michael as he wrote a poster on some of the cases and took part in the discussion.

The Following document is a Request for Information (RFI) response received by the Scottish Hospital Inquiry from NHS GGC

Scottish Hospitals Inquiry/NHSGGC - Request for Information dated 15th April 2024 (SHI RFI 26)

Please provide the following information from NHSGGC regarding Cryptococcus at QEUH/RHC from 26th January 2015 to date:

(1) Confirmation of the total number of Cryptococcus cases/infections in patients at QEUH/ RHC between 26th January 2015 to date:

There were two known Cryptococcus cases / infections in patients at the QEUH / RHC between 26th January 2015 to date. Please see Appendix 1 Patient Summaries. These were Patient 2 and Patient 4. Their associated blood culture and serology test data is included in Appendix 2.

a) Confirmation of the number of all positive test results for Cryptococcus infection(s):

Cryptococcus infections can be detected in patients using different tests:

- Blood culture test, which is a medical laboratory test used to detect bacteria or fungi in a person's blood.
- Serology tests, these are blood tests that look for antibodies in a person's blood.

Please note a positive test does not assure infectivity, the result may be a false positive.

There were a total of **24 positive Cryptococcal Serology tests** from patients who had samples taken whilst they were in the QEUH / RHC between 26/01/15 until 12/04/24.

There were a total of **17* blood culture tests** which were positive for Cryptococcus from patients who had samples taken whilst they were in the QEUH / RHC between 26/01/15 until 12/04/24.

*Note 2 of these were non-invasive samples.

Patients have multiple tests, blood culture and/or serology throughout their inpatient stay. A total of 10 patients had samples taken whilst they were an inpatient in the QEUH/RHC which were positive for Cryptococcus (either positive blood culture and/or positive serology test).

Appendix 1 includes summaries for each of the patients who had samples taken whilst they were in the QEUH/RHC between 26/01/15 until 12/04/24 which were positive for Cryptococcus (either positive blood culture and/or positive serology test).

Appendix 2 includes corresponding details of the positive blood culture and/or serology tests for patients who had samples taken whilst in the QEUH/RHC and any associated negative serology tests. This includes patients who had a

positive blood culture and/or serology test before they were transferred to QEUH/RHC but who were subsequently cared for and had further samples taken in QEUH/RHC. For completeness, blood culture and serology test results for *Cryptococcus* from samples that were taken from these patients whilst they were in another NHSGGC hospital location are also included.

b) Confirmation of the number of all negative test results for *Cryptococcus* infection(s):

There were a total of **661 negative *Cryptococcal* Serology tests** from patients who had samples taken whilst they were a patient in the QEUH/RHC between 26/01/15 until 12/04/24.

Blood culture tests which were “negative” for *Cryptococcus* are all other blood culture tests undertaken which did not detect *Cryptococcus*, the number of which is voluminous.

c) Confirmation of the number of inconclusive test results, which have not later resulted in either a positive or negative result(s); and

There were no intermediate serology results.

d) With the numbers provided taking into account all variations or strains of *Cryptococcal* infection(s)

These have been included in the figures.

(2) Except insofar as already provided, full details of all or all or any response or reporting action taken in respect of positive cases of *Cryptococcus* at QEUH/ RHC from 26th January 2015 to date, please see the Inquiry’s position regarding information already submitted below.

NHSGGC has previously provided the Inquiry with all of the information relating to the response or reporting action taken in respect of the two confirmed positive cases of *Cryptococcus* at the QEUH/RHC from 26/01/15 until 12/04/24.

This information relating to the two confirmed positive cases was previously provided under:

- RFI 1 6 water and cryptococcus timeline (IMT minutes and commentary),
- RFI 7 2.17 (minutes of *Cryptococcus* IMT Expert Group, reports considered by that group, and final unredacted report of that group),
- RFI 7 5.3, 5.5 and 5.7 (correspondence, reports etc around IMT investigations, pigeons etc),
- RFI 7 5.6 (Dr Kennedy’s *cryptococcus* epidemiology report), RFI 7 2.23 (summary of investigations outwith IMT).

(3) In respect of the Report from the Cryptococcus Incident Management Team Expert Advisory Sub-Group dated 5th April 2022:

a) Confirmation of when this report was submitted/sent by NHS GGC to NSS, along with any accompanying correspondence.

The Report from the Cryptococcus Incident Management Team Expert Advisory Sub-Group dated 5th April 2022 was emailed to NSS on 07/04/2022, accompanying the report was a list of responses to NSS's comments on the draft version of the report.

The email is attached: ARHAI April and May correspondence 2022.pdf

b) Details of the response, if any, from NSS in respect of the report, along with any communications from NSS to NHS GGC in respect of the views if NSS regarding the report.

An initial response was received from NSS on 28/04/2022, this is contained in the attached ARHAI April and May correspondence 2022.pdf

Also attached are three tables which list comments provided by HFS and ARHAI and the response to the comments by the Sub-group.

- 250321 Response to ARHAI HFS comments on draft report.doc
- 2nd Response to ARHAI HFS comments on draft report 30 04 21.doc
- 05 11 21 Response to ARHAI HFS Comments on DRAFT Crypto Report.pdf

c) Confirmation of NHS GGC's understanding of whether NSS were supportive of the report, along with any documentation, correspondence, or information provided by NSS confirming their support of NHS GGC's position.

NHSGGC's understanding is that ARHAI were not supportive of all the findings of the report and requested to be removed as authors of the report.

Appendix 1: Patient summaries for patients who had samples taken whilst they were in the QEUH/RHC between 26/01/15 until 12/04/24 which were positive for Cryptococcus (blood culture and/or Cryptococcal Serology tests)

Patient No	Patient Summary
Patient 1	Specimen date: [REDACTED].12.2020: Skin swab and tissue sample [REDACTED] No acute features of cryptococcal infection noted at clinic however commenced on fluconazole on advice of microbiology. Patient History: Immunosuppressed patient [REDACTED]. Patient was a pigeon keeper/racer. Last admission to NHSGGC prior to specimen date was [REDACTED].10.20 [REDACTED]
Patient 2	Confirmed Cryptococcus Case – Information previously provided to the Inquiry: • RFI 1 6 water and cryptococcus timeline (IMT minutes and commentary), • RFI 7 2.17 (minutes of Cryptococcus IMT Expert Group, reports considered by that group, and final unredacted report of that group), • RFI 7 5.3, 5.5 and 5.7 (correspondence, reports etc around IMT investigations, pigeons etc), • RFI 7 5.6 (Dr Kennedy's cryptococcus epidemiology report), RFI 7 2.23 (summary of investigations outwith IMT). • RFI 7 2.17 unredacted final report includes clinical details of the case and is the most succinct source.
Patient 3	Specimen date: [REDACTED].10.16 CSF taken @ RAH Ward 2AMU. [REDACTED].02.17 CSF taken @ QEUH Ward 5c. Patient History: [REDACTED] Transferred to Ward 5c QEUH 12.10.16. During this admission patient tested positive for [REDACTED] (new diagnosis). Re admitted with Cryptococcus in CSF again February 2017.
Patient 4	Confirmed Cryptococcus Case – Information previously provided to the Inquiry: • RFI 1 6 water and cryptococcus timeline (IMT minutes and commentary), • RFI 7 2.17 (minutes of Cryptococcus IMT Expert Group, reports considered by that group, and final unredacted report of that group), • RFI 7 5.3, 5.5 and 5.7 (correspondence, reports etc around IMT investigations, pigeons etc), RFI 7 5.6 (Dr Kennedy's cryptococcus epidemiology report), RFI 7 2.23 (summary of investigations outwith IMT).

	RFI 7 2.17 unredacted final report includes the clinical details of the case and is the most succinct source.
Patient 5	Isolate from 2020, related information previously provided to the Inquiry: - IMT minutes submitted to SHI under Section 21 no.2 1.1.7. Additional correspondence in relation to this patient has also been provided with this response: - CP Email re weekly report.docx - Email re investigation 29.06.20 - Redacted V1.0.pdf - Email re lab results.docx - HIIORT 02.07.20.docx - HIIORT 09.07.20.docx - HPS Return 02.07.20.docx - JH Plant Room Inspection 03.07.20.docx - List of admissions [REDACTED].docx - RHC AHU Walk round 6 July 2020.docx - SBAR [REDACTED] case 30 June 2020.doc - Timeline for Patient [REDACTED].docx - Update on CSF PCR 08.docx - Update to HPS 08.07.20.docx
Patient 6	Transferred from [REDACTED].03.21 with suspected fungal lesions. [REDACTED] possible cryptococcal antigen detected. [REDACTED]
Patient 7	Non-invasive sample Specimen Date [REDACTED].12.15 (mouth) Mouth swab taken in ED isolated <i>Cryptococcus laurentii</i> Patient History: Patient attended RHC ED [REDACTED].12.15 presenting with rash [REDACTED] Routine bacterial screen obtained which included mouth swab. Patient had no previous admissions before or since this attendance.
Patient 8	Specimen date: [REDACTED].11.16: Clotted blood antigen positive. Discharged the day sample was taken, no further mention of this in micro notes or clinical notes. Patient history: Patient was complex congenital HIV positive. [REDACTED].

Patient 9	Specimen date: [REDACTED].04.23: Blood culture taken on admission to RAH ED isolated <i>Cryptococcus neoformans</i>, with subsequent positive isolates form CSF. Patient History: [REDACTED] [REDACTED] Transferred to QEUH ID unit [REDACTED].04.23 for treatment of <i>Cryptococcus</i> meningitis.
Patient 10	Non-invasive sample Specimen Date [REDACTED].10.17 Patient History: Patient has history of [REDACTED] kidney disease and [REDACTED]. Regular admissions to renal ward before and after isolate. Last admission to RHC prior to isolate was [REDACTED].09.17 to [REDACTED].09.17. Admitted to Ward 3c on [REDACTED].10.17 after [REDACTED] noticed peritoneal fluid was blood stained. Patient discharged home [REDACTED].10.17. Peritoneal dialysis fluid taken on admission to Ward 3c RHC [REDACTED].10.17 isolated <i>Cryptococcus curvatus</i>.

Appendix 2: Corresponding details of the positive blood culture and/or serology tests for patients who had samples taken whilst in the QEUH / RHC and any associated negative serology tests. For completeness, blood culture and serology test results for *Cryptococcus* from samples that were taken from these patients whilst they were in another NHSGGC hospital location are also included.

Contraventions

Maternity Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Filling Loop	Maternity Boiler Room	Boiler Room	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	Install suitable backflow prevention to provide Fluid Category 4 protection.	Provide Fluid Category 4 protection for quick fill filling loop for heating system.
Fire Hose Reel	Maternity Building	Full Building	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Install a double check valve	Install a double check valve back at source or on supply pipe to each fire reel. Also put in place a flushing program for fire reels.
Main Inlet	Maternity Boiler Room	Plant Room	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	install stop valve, double check valve and drain valve on incoming supply	
Main Inlet	Maternity Building	Unknown	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	install stop valve, double check valve and drain valve on incoming supply	Locate incoming supply pipe and install stop valve (BS1010), double check valve and drain valve.
Shower	Maternity Building	Full Building	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Restrain shower head	Restrain all shower heads.

Energy Centre

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Filling Loop	Energy Centre Building	Next to heating pressure unit	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	Install suitable backflow prevention to provide Fluid Category 4 protection.	Quick fill filling loop to top up heating system requires category 4 protection.
Main Inlet	Energy Centre Building	Mains Incoming Water Supply	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	install stop valve, double check valve and drain valve on incoming supply	

Adult and Children Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Hose Union Taps	Adult and Children Building	Basement Hydro Pool Plant Room	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Install a backflow prevention device to provide Fluid Category 5 protection.	This union hose tap must be fed from a storage cistern which incorporates a category 5 air gap or replace with bib tap and install double check valve on supply pipe.
Pipework	Adult and Children Building	Water Tank Room	03/08/2020	5	Dead Leg of Pipe Work - High Risk	Disconnect at relevant point so that no stop end at pipe work remains. Failure to remove may increase the risk of Legionella bacterial growth	Put flushing program in place at trade tank 1 & 2 on drain off outlets to lower the risk of Legionella bacterial growth.
Reduced Pressure Zone Valve (RPZ)	Adult And Children Building	Plant Room 31 3rd Floor	03/08/2020	4	RPZ Valve has not been commissioned/tested	RPZ Valve must be commissioned / tested by qualified tester annually.	Please provide test certificate from qualified tester.
Reduced Pressure Zone Valve (RPZ)	Adult And Children Building	Children Building Plant Room	03/08/2020	4	RPZ Valve has not been commissioned/tested	RPZ Valve must be commissioned / tested by qualified tester annually.	RPZ valve feeding hydrotherapy pool needs commissioned /tested by qualified tester also re-installed away from electrical appliances.
Shower	Adult And Children Building	Full Building	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Restrain shower head	Restrain all shower heads on site.
Stop Valve	Adult And Children Building	Basement Fire Fighting Tank	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Install BS1010 stop valve	Install BS1010 stop valves on the main inlet supply pipe to both firefighting tank.
Warning Pipe	Adult and Children Building	Water Tank Room	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Install warning pipe	Reconfigure all early warning pipes in water tank area to correct air gap.

Teaching and Learning

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Filling Loop	Teaching and Learning	4th Floor Boiler Room	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	Install suitable backflow prevention to provide Fluid Category 4 protection.	Install category 4 protection on supply pipe to the quick fill filling loop for heating system.
Reduced Pressure Zone Valve (RPZ)	Teaching And Learning	4th Floor Boiler Room	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	RPZ Valve must be commissioned / tested by qualified tester annually.	RPZ Valve supplying heating system must be commissioned / tested by qualified tester annually.
Shower	Teaching And Learning	Full Building	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Restrain shower head	Restrain all shower heads.

Westmarc Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Filling Loop	Westmarc Building	Boiler room	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	Install suitable backflow prevention to provide Fluid Category 4 protection.	Quick fill filling loop for heating system must have fluid category 4 protection installed.
Main Inlet	Westmarc Building	Boiler Room	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Install a Double Check Valve and a Drain Valve	Install a double check valve and drain valve on the mains water incoming supply pipe.

Neonatal Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Filling Loop	Neonatal Building	Plant Room	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	Install suitable backflow prevention to provide Fluid Category 4 protection.	Quick fill filling loop for heating system must have Fluid Category 4 protection.
Main Inlet	Neonatal Building	unknown	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	install stop valve, double check valve and drain valve on incoming supply	Locate and install - Possible location ground floor fire exit door in pipe chase.
Pumps	Neonatal Building	Secondary Filter Water Tank	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	This equipment must be fed from a storage cistern that incorporates a AA, AB or AD air gap	Pump booster Set must be fed from a storage cistern that incorporates an AA, AB or AD air gap.
Shower	Neonatal Building	Full Site	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Restrain shower head	Restrain all shower heads on site.

Neurology Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Pumps	Neurology Building	Level 6 Plant Room Water tank	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	This equipment must be fed from a storage cistern that incorporates a AA, AB or AD air gap	All booster sets fed from storage cistern must incorporate a AA,AB or AD air gap
Reduced Pressure Zone Valve (RPZ)	Neurology Building	Neurology Boiler House	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	RPZ Valve must be commissioned / tested by qualified tester annually.	This RPZ valve also needs re-installed sighted wrongly too high.
Shower	Neurology Building	Full Building	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Restrain shower head	Restrain all Shower heads.

Landlangs Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Filling Loop	Landlangs Building	Boiler room	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	Install suitable backflow prevention to provide Fluid Category 4 protection.	Quick fill filling loop for heating system requires fluid category 4 protection.
Filling Loop	Landlangs Building	Boiler room	03/08/2020	4	Insufficient Backflow Prevention for Category 4 Contamination Risk	Install suitable backflow prevention to provide Fluid Category 4 protection.	Quick fill filling loop for heating system requires fluid category 4 protection.
Pumps	Langlands Building	2nd floor plant room b	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	This equipment must be fed from a storage cistern that incorporates a AA, AB or AD air gap	Booster pump sets must be fed from a storage cistern that incorporates an AA, AB or AD air gap.
Shower	Langlands Building	Full Building	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Restrain shower head	Restrain all shower heads.

PDRU And Vascular Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Main Inlet	PDRU And Vascular Building	Unknown	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	install stop valve, double check valve and drain valve on incoming supply	Locate incoming supply pipe and install stop valve (BS1010) ,double check valve and drain valve.
Pumps	PDRU And Vascular Building	Loft Area	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	This equipment must be fed from a storage cistern that incorporates an AA, AB or AD air gap	The booster pump set in loft area must be fed from a storage cistern that incorporates an AA, AB or AD air gap.
Shower	PDRU And Vascular Building	Full Building	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Restrain shower head	Restrain all Shower Heads.

Laboratory and Medicine Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Pipework	Laboratory and Medicine Building	Laboratory Level 4	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Install a backflow prevention device to provide Fluid Category 5 protection.	Laboratory taps must be fed from a designated category 5 tank supply which feeds labs only. Please confirm if level 4 laboratory taps are fed from domestic tank on level 4 or laboratory tank in basement.
Pumps	Laboratory and Medicine Building	Mortuary Tank 2 In Basement	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	Install a backflow prevention device to provide Fluid Category 5 protection.	Booster pump set fed from mortuary tank 2 requires category 5 protection.

CMB Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Fire Hydrant	CMB Building	At hydrant on grass verge left hand side of main entrance door	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Remove	Remove temporary water supply from fire hydrant to CMB building and install a permanent supply which meets the water bylaws regulations.
Main Inlet	CMB Building	Unknown	03/08/2020	5	Dead Leg of Pipe Work - High Risk	Disconnect at relevant point so that no stop end at pipe work remains. Failure to remove may increase the risk of Legionella bacterial growth	The old water mains incoming supply pipe needs disconnected back at source. Please confirm if this has been done.

AMB Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Pipework	AMB Building	Unknown	03/08/2020	5	Dead Leg of Pipe Work - High Risk	Disconnect at relevant point so that no stop end at pipe work remains. Failure to remove may increase the risk of Legionella bacterial growth	This building is vacant please confirm if pipework has been capped off back at source.

Max Fax Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Pipework	Max Fax Building	Lab Area - Grinder Machine	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Install a double check valve	Install double check valve on supply pipe to dental grinder.

Podiatry Building

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Main Inlet	Podiatry Building	Plant Room	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Install a Double Check Valve and a Drain Valve	Install Double check valve and drain valve on incoming supply pipe.

Whole Site

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Bath	All Buildings	Arjo Baths	03/08/2020	5	Insufficient Backflow Prevention for Category 5 Contamination Risk	This equipment must be fed from a storage cistern that incorporates a AA, AB or AD air gap	Arjo Baths must be fed from a designated storage cistern that incorporates a AA, AB or AD air gap. Rhapsody/Primo P200+ Location- NSGH-02-DMW-013 NSGH-02-DMW-011 NSGH-01-STW-079 NSGH-06-GENW1-001 NCH-04-DCFP-038 NCH-03-GW3-059 NCH-03-GW1-068 NCH-02-SCH-079 NCH-02-ARU-006 NCH-01-CCW-051 NCH-01-CAR-048
Main Inlet	Full Site	All boundary incoming supply	03/08/2020	3	Insufficient Backflow Prevention for Category 3 Contamination Risk	Install a double check valve to give whole site protection	Install a double check valve to all main inlet boundary's supply points. location- Meter -11W712602 150MM X-253618/Y-665875 06M440901/03H000872 80/20 COMBI X-253329 Y-665758 3K220000653954 150MM X-253443 Y-665842 09H701812/09M102281 80/20 COMBI X-253547 Y-665541 11W727521/19W711190 100MM X-253815 Y-665585 11H762937/11M686368 80/20 COMBI X-253790 Y-666042

Recommendations

Premise Fitting	Area	Location	Recommendation
Fire Hydrant	Full Site	Full Site	All fire hydrants on site to have flushing program in place to remove any risk of legionella bacterial growth.

Comment/Issues

Premise Fitting	Area	Location	Comment/Issue
Pipework	Neuro-Surgical Plant Room 9	Plant Room 9	This area is under renovation and has double check valve in place. This area will require a revisit in one years' time once work has been completed.

Contraventions

Premise Fitting	Area	Location	Due By	Risk	Contravention	Rectification	Comments
Bath	Full site	'Arjo' baths	21/03/2022	5	Insufficient backflow prevention for fluid category 5 contamination risk.	Install suitable backflow prevention to provide fluid category 5 protection.	Arjo Baths - this equipment must be fed from a designated storage cistern that incorporates an AA, AB or AD air gap. Rhapsody/Primo P200+ Location-NSGH-02-DMW-013 NSGH-02-DMW-011 NSGH-01-STW-079 NSGH-06-GENW1-001 NCH-04-DCFP-038 NCH-03-GW3-059 NCH-03-GW1-068 NCH-02-SCH-079 NCH-02-ARU-006 NCH-01-CCW-051 NCH-01-CAR-048
Filling Loop	Energy Centre Building	Next to heating pressure (unit	21/03/2022	4	Insufficient backflow prevention for fluid category 4 contamination risk.	Install suitable backflow prevention to provide fluid category 4 protection.	Quick fill filling loop to top up heating system requires fluid category 4 protection.
Filling Loop	Teaching and Learning	4th floor boiler room	21/03/2022	4	Insufficient backflow prevention for fluid category 4 contamination risk.	Install suitable backflow prevention to provide fluid category 4 protection.	Quick fill filling loop to top up heating system requires fluid category 4 protection.
Filling Loop	Westmarc Building	Boiler room	21/03/2022	4	Insufficient backflow prevention for fluid category 4 contamination risk.	Install suitable backflow prevention to provide fluid category 4 protection.	Quick fill filling loop to top up heating system requires fluid category 4 protection.

Filling Loop	Neonatal Building	Plant room	21/03/2022	4	Insufficient backflow prevention for fluid category 4 contamination risk.	Install suitable backflow prevention to provide fluid category 4 protection.	Quick fill filling loop to top up heating system requires fluid category 4 protection.
Filling Loop	Maternity boiler room	Boiler room	21/03/2022	4	Insufficient backflow prevention for fluid category 4 contamination risk.	Install suitable backflow prevention to provide fluid category 4 protection.	Quick fill filling loop to top up heating system requires fluid category 4 protection.
Filling Loop	Landlans Building	Boiler room	21/03/2022	4	Insufficient backflow prevention for fluid category 4 contamination risk.	Install suitable backflow prevention to provide fluid category 4 protection.	Quick fill filling loop to top up heating system requires fluid category 4 protection.
Hose Union Taps	Adult and Children Building	Basement hydro pool plant room	21/03/2022	5	Insufficient backflow prevention for fluid category 5 contamination risk.	Install suitable backflow prevention to provide fluid category 5 protection.	This union hose tap must be fed from a storage cistern which incorporates a fluid category 5 air gap or replace with bib tap and install double check valve on supply pipe.
Main Inlet	Energy Centre Building	Mains incoming water supply	21/03/2022	3	Insufficient backflow prevention for fluid category 3 contamination risk.	Install suitable backflow prevention to provide fluid category 3 protection.	Install stop valve (BS1010), double check valve and drain valve on incoming supply.
Main Inlet	PDRU And Vascular	Unknown	21/03/2022	3	Insufficient backflow prevention for fluid category 3 contamination risk.	Install suitable backflow prevention to provide fluid category 3 protection.	Locate incoming supply pipe and install stop valve (BS1010), double check valve and drain valve.
Main Inlet	Full site	All boundary incoming supply	21/03/2022	3	Insufficient backflow prevention for fluid category 3 contamination risk.	Install suitable backflow prevention to provide fluid category 3 protection.	Whole site protection - install a double check valves to all main inlet boundary supply points. Care facility/hospital		Royal Hospital for Children	
Clinical area/ward and speciality		Haemato-oncology ward	
Total number of beds		25 (2 out of use for refurb & 2 out of use due to contaminated water outlets) = 21 beds in use	
Total number of beds occupied		21	
Section 3: Initial assessment			
Type: Incident/outbreak/ data exceedance e.g. Gastrointestinal, decontamination failure		Water contamination	
Infectious agent known or suspected		Cupriavidus pauculus/Pseudomonas aeruginosa	
Case definition	Patient with bacteraemia secondary to Cupriavidus pauculus or Pseudomonas aeruginosa Patient with bacteraemia due to Stenotrophomonas		
Date of first case (if applicable)			
Total number of confirmed patient cases	Total number of probable patient cases	Total number of possible patient cases:	Total number of staff cases:
4	0	0	0
Number of patients giving clinical cause for concern as a consequence of this incident/outbreak		0	
Number of deaths as a consequence of this incident/outbreak		0	
Was the infectious agent cited as a cause of death on a death certificate* (if yes, state which part of the certificate)			
Additional information: Patient presented at end of January with Cupriavidus pauculus bacteraemia. Responded to treatment. As part of the investigations a selection of water outlets in ward 2A were sampled and have tested positive - 4 patient rooms , treatment room and prep room. Note there is currently a patient on the unit with Pseudomonas aeruginosa bacteraemia which is healthcare associated. One outlet has tested positive for this organism Due to the number of positive outlets we will not test anymore at present . We assume widespread problem so will proceed straight to dosing the system with Silver Hydrogen peroxide. Taps and components including flow straighteners have been removed for sampling. Water tanks have also been sampled

Section 5: Organisational Arrangements		
PAG/IMT meeting held	Yes	Date: 5/2/18 & 19/2/18 & 1/3/18
Next planned IMT	Early week beginning 5 th March	Date:
Press statement (send with HIIORT or provide date for receipt)	Draft awaited Date:	
HPS support requested	Not at present	Date.....
Other information: e.g. decisions from IMT	Water checklist carried out – concerns identified and issued as an SBAR to clinical SMT Initial rooms identified as having contaminated outlets taken out of use. All showers out of use. Patients going for line insertion in theatre will have a bed bath down in theatre. All staff and patients to use alcohol based hand rub after washing hands Bottled water for teeth brushing Ongoing surveillance by ICT for further cases 2/3/18 IMT held. Water dosing will take place today with Sanosil. Estates have commenced replacement of outlets. Results from main water tanks are negative suggesting outlets themselves are the source. Water supply to ward will go down for 4 hours , hand hygiene stations will be put in place using bottled water. Patients will be given sterile water to drink. Once dosing complete outlets will be put back in use and resampling will take place early next week. HIIAT remains at Red. 06/03/18 IMT held. No new patient cases. Patient with Pseudomonas is stable. Microbiological testing is still in progress but several components of the tap including the flow straighteners have tested positive for Cupriavidus. Showerhead has also grown the organism. All flow straighteners will be replaced. Disposable showerheads will be purchased and fitted for this ward. Water sampling to move from 6 monthly to monthly. Alerts set up on ICNet for Cupriavidus in blood cultures. One other Cupriavidus pauculus bacteraemia in 2A , September 2017 but water testing had been negative so not clear if linked to current incident . Isolate has been sent for typing. Working hypothesis is that outlets are positive due to contact spread as main tanks are negative. HIIAT remains Red 09/03/18 IMT held. No new patient cases. A program of tap exchange, thermal disinfection and replacement of flow straighteners is ongoing. Once all taps have been changed there will be a further chemical disinfection . Resampling will take place after chemical disinfection. Water testing has been extended to ward 2B which is the outpatient area. HIIAT will remain at Red until repeat sampling post 2nd chemical disinfection . 12/03/18 Urgent IMT reconvened following positive water isolates after sanitisation indicating that the sanitisation process has been ineffective. Water has grown Cupriavidus(multiple outlets) and Stenotrophomonas (one shower head only). The most likely scenario is that dosing has disrupted the biofilm leading to the release of bacteria into the water. One patient colonised with Stenotrophomonas (not related to the positive room) . No patients giving cause for concern. Following control measures were immediately put in place; • All showers and baths out of use for patients. • Patients going for line insertion in theatre will have a bed bath down in theatre. • All staff and patients to use alcohol based hand rub after washing hands on ward 2A and 2B. • Bottled water for teeth brushing in ward 2A & 2B • Ongoing surveillance by ICT for further cases • Disposable shower heads to be installed this evening • Portable sinks will be delivered to the ward this evening and filled over night. • All taps to be cleaned and have replacement flow straighteners and TMVs • Chemical sanitisation of the ward will commence at 6am tomorrow • Portable sinks will be deployed and remain in use until clear samples are achieved post sanitisation.	

- The program of replacing Horne taps ASAP will re-commence following sanitisation.
- Water supply in ward 3C will be tested as a contingency for failure of the current plan.
- Comms prepared for parents.
- Holding press statement updated.
- Further IMT to be arranged later in the week.

IMT 19.03.19 Update

Infection Control Measures

The following control measurements are for immunocompromised patients with Ward 4B, 4C, 7A, 7D which include Cystic Fibrosis and Renal transplant patients:-

- Patient must not wash/be washed/drink or brush teeth with water from the sink or shower outlets.
- Only drink bottle water (Patients are allowed to drink cups of tea)
- Use bottle water to brush teeth
- Washing must be used with single use patient wipes/bottled water.

Please note that sterile water should be used if it is a Bone Marrow Transplant (BMT) patient.

All rooms with immunocompromised patients are to get a twice daily Actichlor cleans.

The group asked about patients within critical care, Dr Inkster informed them that the patients would not be taking showers or using clinical hand wash basins if in critical care.

Water Control Measures

Point of use filters will be installed on all Clinical Hand Wash basins within Ward 4B as well as replacement of shower heads and hoses. Once complete testing of the water will recommence and when negative specimens obtained, patients can start using the main water supply. This should take approximately 48 hours.

The above precautions are for short term only. Long term solutions are currently being investigated which include replacing all current taps within the hospital and the dosing of the water supply with Chlorine Dioxide.

HIIAT Assessment

The group agreed that the HIIAT should be RED.

IMT 21.03.19 Update

Patient Update RHC

Ward 2A

All 3 positive blood culture *Stenotrophomonas* patients have had their lines taken out and are currently stable and causing no concerns to staff.

Patient Update QEUH

No positive blood cultures for *Stenotrophomonas* or *Cupriavidus* in Ward 4B

There have been no new cases since the implementation of the control measures.

Epidemiology

Since the opening of the RHC site there have been 3 cases of Cupriavidus reported. This is a very rare pathogen which is linked to dialysis lines and water. Strong epidemiology link with the Cupriavidus and water with the positive results from the water outlets.

Cases of Stenotrophomonas have spiked to 4 cases during the month of March 2018 in RHC 2A. There is usually about 1 case of Stenotrophomonas a month within the RHC site. In ward 4B QEUH site only one case of Stenotrophomonas has ever been reported since opening. In ward 2A it is unclear whether we can link to this to water as it has only been found in one shower outlet. However the counts were high at >100 and we only sampled limited outlets assuming widespread contamination with Cupriavidus. Originally it was thought the Stenotrophomonas was being transmitted through patients taking showers. The other possibility is that the index case is water related and subsequent cases were transmitted from HCW to other patients or all cases may be completely independent from the water supply.

Typing results will shed light on the Cupriavidus as it will show if there has been a link with cross transmission from water outlet to patient.

Cannot determine if Stenotrophomonas is water source or cross transmission until typing results come back.

RHC Water Report

Ward 2A wide spread positive results for Cupriavidus in multiple sink outlets, 2 positive shower outlets with Stenotrophomonas and 1 outlet with pseudomonas. Dosed system 4 times and have seen the counts being lowered but Cupriavidus still present in number of outlets.

Ward 2B and 3C still have widespread Cupriavidus

Fungal matter found in water supply in 2B and 3C but levels not dramatic and it is not uncommon to find this in hospital environments. None of the fungus has been identified as significant to date. No issues with Aspergillus were found within the samples although noted an issue with lab contaminants. Fungus in the water supply is a concern particularly for BMT patients and this has been discussed with experts. Control measures will need to take this into account moving forward.

Ward 4B QEUH Water Report

Two positive results of Cupriavidus from shower head in ward 4B. Multiple water samples positive from outlets in 4B

Sampling being carried out on 21.03.18 within occupied bed areas in Ward 4B QEUH.

Other Reports

The two sources of water coming into the hospital from Hardgate road and Govan road have both came back negative from samples taken by Scottish Water. Low levels of another bacteria were identified but within acceptable limits and there is no evidence of this bacteria in our tanks indicating that filtration is working.

It was reported that the two main water storage tanks, filter tanks and booster pumps have all came back negative.

Renal dialysis samples are within normal limits

There are no concerns re aseptic pharmacy results – successive results are negative

Other Relevant reports

Samples were taken of soap dispensers, liquid soap, wipes and an array of commonly used items domestic use. Initial results from the samples after 24 hours is negative but still have to wait until 48 hours until incubation period is complete.

Current Infection Control Measures

The following specific control measurements for immunocompromised patients are as follows

- Patient must not wash/be washed/drink or brush teeth with water from the sink or shower outlets.
- Only drink bottle water
- Use bottle water to brush teeth
- Wash must be used by single use patient wipes/bottled water or water from the mobile hand wash units which are available in Ward 2A.
- Parents and staff can use sinks for hand hygiene but use AHR afterwards.

Please note that sterile water should be used if it is a Bone Marrow Transplant (BMT) patient.

All rooms with immunocompromised patients are to get a twice daily Actichlor cleans which consists of all rooms in ward 2A and any inpatients throughout RHC.

If staff are to carry out an aseptic technique on a patient then they must carry out hand hygiene a surgical scrub with bottled water then followed by use of sterillium.

Ciprofloxacin is still to be given to all immunosuppressed patients in the meantime but this will not be a long term. Janice Watt informed the group that Pharmacy are currently going through 50 bottles of Ciprofloxacin a week. She is mostly concerned that the long term supply of liquid form Ciprofloxacin mostly used for paediatric patients compared to the tablet form given to adults.

Water Control Measures

Tap and shower filters have been fitted in Ward 2A, 2B, 3C in the RHC and occupied beds in Ward 4B Haematology, QEUH (unoccupied rooms being done later this week). Filters are currently being fitted to NICU today with sampling being taken from PICU before filters being installed.

Director of regional will inform facilities colleagues regarding what areas should be prioritised within the QEUH for the fitting of water filters into Ward 4A, 4C, 4D, 7A and 7D.

Quality assurance of the fitting of the filters will be carried out by Facilities.

The group was informed that that to completely know if the filters work they would need to identify a positive water outlet that has not been dosed with silver nitrate, fit the filter and resample to see the results.

It was agreed once facilities can confirm that filters have been fitted to all CWHB and showers and checked they have been fitted correctly then patients can resume using showers and wash hand wash basins.

Facilities will carry out tests on the water outlets on a weekly basis to ensure the filter is working. If the counts start to get high then they can change the filters on the affected outlets. The filters currently fitted to the taps have a working life of 30 days. Facilities have are introducing a rolling program to change these filters from day 25.

Water coolers are to be kept out of use within in patient areas.

There was extensive discussions within the IMT re whether microbiological efficacy of filters was required prior to using the water. The consensus of the IMT was that we would proceed with filters without these results. Post meeting this decision was supported by Peter Hoffman Public Health England and Susanne Lee, International water expert.

Future Preventative Measures

Currently two future preventable measures are being looked at.

One of the measures is the installation and replacing of all horne taps within high risk areas or throughout the whole QEUH and RHC campus with the later being very time costly and time consuming. Two tap models are currently being investigated

The other preventable measure being looked at is the dosing of the water system with Chlorine dioxide. This would need expert opinion on how this could be implemented due to the size of the campus and the water holding tanks.

Hypothesis

It was explained that Scottish water reported that main tanks are negative. Post filtration tanks and risers are negative. The bacteria concerned like oxygen and taps/showers are heavily contaminated. Tap and shower components are conducive to biofilm especially flow straighteners and plastic.

It was explained there may have been contamination in the past with organisms being flushed through the system but forming biofilm on the outlets .

HIIAT Assessment

The group agreed that the HIIAT should remain at RED.

IMT 27.03.18

Patient Update RHC

Ward 2A

The three affected patients are not giving medical staff any cause for concern.

PICU

No concerns regarding the patient in PICU.

Patient Update QEUH

No cases reported

RHC Water Report

Pre filter water results have come back showing numerous outlets within PICU positive with Cupriavidus and numerous outlets positive with Sphingomonas in NICU. Point of use filters have been fitted to CWHB outlets in these areas.

The group were informed that most of the positive tests are coming back as Cupriavidus, although these checks were all pre filter tests.

Positive results for Delftia has come back from testing carried out in theatres, RHC. LICD has requested filters are to be fitted there.

RHC therefore has evidence of widespread problem

Ward 4B QEUE Water Report

Pre filter results from water sampling within Ward 4B QEUE have different Microbiology results than Ward 2A, RHC. There is a mixture of gram negative pathogens with some outlets testing positive for high counts of fungal growth. Bacteria include Delftia sp, Commanonas sp, Achromobacter sp and Cupriavidus.

The water risers for Ward 4A and 4D have come back positive, but some of the water outlets are negative. Samples from Level 6 & 7 have come back negative. Dr Inkster has requested water testing on Level 5 to see if any pathogens are moving up the building.

Overall gram negative pathogens and fungal counts some greater than 100 have been found throughout the QEUE and RHC sites. Fungal counts should not be higher than 10 and some of the gram negative pathogens are significant, particularly for immunosuppressed patients.

Additional alerts have been put on IC net within NHSGGC to capture a suggested list of microorganisms associated with water at the suggestion of HPS. These infections will now be monitored at least in the short term to identify and issues.

Other Reports

Neuro and Maternity buildings are negative for everything with counts of zero due to historic chlorine dioxide dosing to the water supply to the buildings.

Initial typing results are showing 2 different strains of Cupriavidus. The group will need to wait until the patient typing results are returned to see if they are the same.

Patient pseudomonas bacteraemia is a different organism from the pseudomonas found from sampling. The group has decided to exclude this patient case from the incident as it is not linked to any of the samples taken.

Did not sample Ward 2A drains as numerous doses of Sansil has been put down the drains. Ward 2B, RHC and ward 4B, QEUE have been sampled. Both have come back with Stenotrophomonas, Elizabethkingia and Pseudomonas species.

Current Infection Control Measures

The group agreed to step down the Infection Control measures put in place for affected wards within the QEUE and RHC sites as point of care filters have been fitted to all water outlets and showers. Patients can now use the CHWB to carry out hand hygiene and also use the showers if required. Patients no longer require Ciprofloxacin.

For the time being BMT patients within the RHC will still have all precautions kept in place.

This was agreed as we need to wait for quality assurance process (4 weeks testing) of the point of use filters. There is a quality assurance from the company but NHGS GG&C has not approved it. The group said a lot of this is down to confidence and can we guarantee the safety of the BMT patients.

Concern was expressed re the testing of filters and whether it was comparable to our situation with multiple bacteria and fungi. Furthermore when used in these situations filters are usually applied for a single organism problem. There are currently 4 BMT patients in RHC at the moment with 1 more BMT expected to be admitted within the

next 4 weeks. Addition precautions would be put in place after discussion within Clinical Staff W & C SMT and IPCT.

*Post IMT it was agreed to proceed with BMT patients but that filters would need to be changed every 7 days as we have proven microbiological efficacy to that point. This will mean BMT patients can shower. One patient was discussed with Edinburgh but will come to RHC –this patient has C diff and strict IC precautions will be applied.

Hypothesis

There are 3 main hypothesis the group are looking into which are -

Could the outlets be contaminated from a back flow from the drains. There is currently no evidence of back flow from drains. Ward 4B and 2B both have positive microbiology but this is different from the water results. LICD observed no backflow and noted that the showers, whilst they can dangle are sitting high above the drains, The group have decided to exclude this as a possible issue.

There is small number of organisms coming in from the main supply in low levels, which over time has built up and formed biofilm on the outlets

Contamination of the pipes during the commissioning of the building. Also the possibility that the taps had been kept in a dusty area for some time until they were all fitted without being cleaned.

The group agreed to look into the air handling system as they use a very coarse filter that does not stop microbiology organisms. LICD stated that you would expect perhaps to see Gram positive organisms also and not just water associated Gram negatives. HFS has experience regarding this and will speak to IPCT when he gets back.

Current Water Control Measures

It was agreed that 12 water tests will be carried within each ward 2A and Ward 4B on a weekly basis. The outlets tested will remain the same throughout the month. Sampling will be carried out on a Monday so that the results will be available later on the week with no results coming in during the weekend. This will be carried out for 4 weeks which is lifetime of the filters and then each filter will be replaced through a rolling program

Facilities have got a table of all point of use filters and shower filters that have been fitted and will forward this onto the group.

Future Preventative Measures

New taps preferable without flow straighteners.

The introduction of a chlorine dioxide dosing of the water supply to RHC and QEUH.

Filters being used on a much longer term basis in high risk wards, defined as 2A and 4B

How do we clean drains throughout the RHC/QEUH sites – Dr Inkster advised using acetic acid and focusing on 2a and 4B first.

HIIAT

The group agreed that the HIIAT score of AMBER after the group agreed there was moderate risk to service and public anxiety and minor risk to severity of illness and risk of transmission.

No further IMT are planned at this time but a separate group chaired by the Acting Director of facilities would be convened to look at long term solutions.

Complete this update section weekly as a minimum if red or amber or as agreed with IMT and HPS for onward reporting to SGHSCD.
